MATHEMATICAL REVIEWS, 190 Hope St., Providence 6, R.I.

Subscription: Price $50 per volume. There will be two volumes in 1965. Checks should be made payable to the AMERICAN MATHEMATICAL SOCIETY. Subscriptions should be addressed to the American Mathematical Society, 190 Hope St., Providence 6, R.I.

The preparation of the reviews appearing in this publication is made possible by support provided by a grant from The National Science Foundation. The publication was initiated with funds granted by the Carnegie Corporation of New York, the Rockefeller Foundation, and the American Philosophical Society held at Philadelphia for Promoting Useful Knowledge. These organizations are not, however, the authors, owners, publishers or proprietors of the publication, and are not to be understood as approving by virtue of their grants any of the statements made or views expressed therein. The comments and opinions expressed in reviews of books and other publications are those of the individual reviewers and do not necessarily represent the views of the Editors or the American Mathematical Society.

Mathematical Reviews will be published in two volumes in 1965; each volume will consist of six monthly issues, and a separate index issue will be published for each volume. Reviews and pages are numbered consecutively.

Journal references in Mathematical Reviews are given in the following form: *Fortschritte der Math.* (6) 5 (56) (1960/61), *no.* 2, 18–53 (1962), where, after the abbreviated title, one has: (series number) volume number (volume number in first series, if given) (nominal date), issue number if necessary, first page—last page (imprint date). If only one date is given, this will usually be interpreted as the nominal date and will be printed immediately after the volume number. If no volume number is given, the year will be used in its place. The symbol ★ precedes the title of a book or other non-periodical which is being reviewed as a whole.

References to reviews in Mathematical Reviews before Volume 20 (1959) are by volume and page number, e.g., MR **15**, 122; from Volume 20 on, by volume and review number, e.g., MR **20** #4387 or MR **23** #A123. Reviews reprinted from Applied Mechanics Reviews, Computing Reviews, Mathematics of Computation, Operations Research, Referativnyĭ Žurnal Matematika (Mehanika, etc.), Science Abstracts, or Zentralblatt für Mathematik are identified in parentheses following the reviewer's name by AMR, CR, MC, OR, RŽMat (RŽMeh, etc.), SA, Zbl, respectively.

Printed in Great Britain by William Clowes and Sons, Limited, London and Beccles

Meschkowski, Herbert 3329

★Einführung in die moderne Mathematik.
B·I-Hochschultaschenbücher, 75.
Bibliographisches Institut, Mannheim, 1964. 189 *pp*.

This book is part of an extensive series of "Hochschultaschenbücher" and provides a brief introduction to the ideas surrounding the elementary mathematical structures. In his foreword, the author reflects that some years ago an introduction to higher mathematics was principally limit calculus, while now it tends to be the science of formal systems. The book contains some problems and their solutions.

Table of Contents: Axioms, Sets, Rational Numbers, Groups, Rings and Fields, Lattices, Spaces, Real Numbers.

P. J. Davis (Providence, R.I.)

Burlak, J. 3330

★Russian-English mathematical vocabulary.
With a short grammatical sketch by K. Brooke. University Mathematical Texts.
Oliver and Boyd, Edinburgh-London; Interscience Publishers, Inc., New York, 1963. viii + 305 *pp*. 21 *s*.

This is (at least) the third Russian-English mathematical dictionary-with-grammar since 1961 (others are Lohwater [*Russian-English dictionary of the mathematical sciences*, Amer. Math. Soc., Providence, R.I., 1961; MR **23** #A3044] and Milne-Thomson [*Russian-English mathematical dictionary*, Univ. Wisconsin Press, Madison, Wis., 1962; MR **24** #A2520]). Although Brooke's grammar has some features that the others lack, notably an alphabetical table of final letters with indications of what they might signify, Lohwater's remains the most helpful because of its large number of illustrative examples from a variety of mathematical fields. All three dictionaries include (apparently random) selections of Russian versions of mathematicians' names; Burlak is particularly strong on those of interest in the history of mathematics, and on British names. Unfortunately, Burlak records the MR transliteration of Russian only as it was before 1962. The reviewer has made a number of spot checks of words from papers in several fields; whereas in most cases any one of the three dictionaries will lead to the correct meaning, at least after a little thought, Lohwater's seems considerably more likely to evoke the correct mathematical idiom. In the reviewer's opinion, a mathematician wanting to buy only one dictionary should still buy Lohwater's.

R. P. Boas, Jr. (Evanston, Ill.)

★Swedish-Russian technical dictionary 3331
[Шведско-русский политехнический словарь].
Compiled by V. F. Maksimov; Edited by L. Ja. Popilov and I. V. Èlhval'd.
Izdat. "Sovetskaja Ènciklopedija", Moscow, 1964. 1257 *pp*. 3.07 *r*.

This dictionary contains approximately 60,000 words and terms; the mathematical vocabulary will be of interest principally to applied mathematicians.

Mikhalszewska, N. E. [Михальшевская, Н. Е.]; Mikhalszewski, R. I. [Михальшевский, Р. И.] 3332

★Polish-Russian mathematical dictionary [Польско-русский математический словарь].
Glavnaja Redakcija Inostran. Naučno-Tehn. Slovarei Fizmatgiza, Moscow, 1963. 213 *pp*. 0.79 *r*.

This dictionary, which has 12,000 entries, will prove useful in reading general mathematics in Polish. The number of entries in the dictionary could have been substantially reduced by the omission of an excessive number of listings of the type $A + B$, where A and B have their customary meanings; for example, there are 146 such entries under "grupa", extending from "grupa abelowa" (abelian group) to "grupa zwarta" (compact group).

★Philosophy of mathematics: Selected readings. 3333
Edited and with an introduction by Paul Benacerraf and Hilary Putnam.
Prentice-Hall, Inc., Englewood Cliffs, N.J., 1964. vii + 536 *pp*. $8.95.

This volume comprises a collection of some of the more important papers on the philosophy of mathematics that have appeared during the last 75 years or so, the majority of them belonging to the more recent period. The papers have been selected in such a way as to present the thread of the argument; the principle of selection is explained in a brief introductory chapter by the editors. There are four main parts, respectively on "The Foundations of Mathematics", "The Existence of Mathematical Objects", "Mathematical Truth", the last section being reserved for passages from Wittgenstein's *Remarks on the foundations of mathematics* [Macmillan, New York, 1956; MR **19**, 1], together with a number of comments and reviews of Wittgenstein's book. Within the four parts, the selection of papers (not in chronological order) is again carried out in such a way that the later papers frequently illuminate those that have preceded, and a particularly pleasing result is that philosophy of mathematics is exhibited in the form of a constant "disputation" (to use the title of Heyting's second paper in Part One). Thus the selection from Russell's *Introduction to mathematical philosophy*

[Allen & Unwin, London, 1919] follows the Frege extract, "The Concept of Number"; Castañeda's paper on "Arithmetic and Reality" blasts its predecessor, D. A. T. Gasking's "Mathematics and the World", etc. And the bibliography supplies additional controversial material where space has limited its reproduction in full.

It would be impossible to single out in detail every paper; some of the names from the list of contributors may give the reader some idea of its breadth and penetration: Carnap, Heyting, von Neumann, Brouwer, Frege, Russell, Hilbert, Quine, Goodman, Gödel, Bernays, Ayer, Nagel, Hempel, Poincaré, Dummett. There is no doubt that this selection will be a classical reference work for many years to come.

G. Buchdahl (Cambridge, England)

HISTORY AND BIOGRAHPY

See also 3359, 4231–4233.

Eves, Howard 3334

★**An introduction to the history of mathematics.**
Revised edition.
Holt, Rinehart and Winston, New York, 1964. xvi + 439 *pp*. $7.95.

The present book, a minor revision of the first edition [New York, 1953], attests the current popularity of the history of mathematics in the schools and universities (see, for example, the recent volume by A. Aaboe [*Episodes from the early history of mathematics*, Random House, New York, 1964; MR **28** #2956] sponsored by the School Mathematics Study Group).

The author has divided his book into two parts. Part I ("Before the Seventeenth Century") deals with numeral systems, Babylonian and Egyptian mathematics, Pythagorean mathematics, the problems of duplication, trisection and quadrature, Euclid's *Elements* and Greek mathematics after Euclid, Hindu and Arabian mathematics, and European mathematics up to 1600. Part II ("Seventeenth Century and Later European Mathematics") deals rapidly with later developments.

Bubnov, Nicolaus (Editor) 3335

★**Gerberti postea Silvestri II papae Opera Mathematica (972–1003).**
Accedunt aliorum opera ad Gerberti libellos aestimandos intelligendosque necessaria per septem appendices distributa.
Georg Olms Verlagsbuchhandlung, Hildesheim, 1963. cxix + 620 *pp*. (4 *plates*) *DM* 98.00.

Der Nachdruck der Originalausgabe [Friedländer, Berlin, 1899] ist sehr zu begrüßen. An ergänzendem Material ist zu nennen: P. Tannery und L'Abbé Clerval [Notices Extraits Manuscrits Bibliothèque Nat. **36** (1901), 487–543] und J. E. Hofmann [Abh. Preuss Akad. Wiss. Math.-Natur. Kl. **1942**, no. 8; MR **8**, 189].

J. E. Hofmann (Ichenhausen)

Kepler, Johannes 3336

★**Gesammelte Werke. Band VIII: Mysterium cosmographicum. Editio altera cum notis *De Cometis*, *Hyperaspistes*.**
Bearbeitet von Franz Hammer.
C. H. Beck'sche Verlagsbuchhandlung, Munich, 1963. 517 *pp*. (3 *inserts*) *DM* 65.00.

The present book is Volume 8 (Volume 7 appeared in 1953) in the planned series of Kepler's works begun by von Dyck and Max Caspar. In it Franz Hammer has presented three of Kepler's late works: Kepler's second and annotated edition of *Mysterium Cosmographicum* of 1621, his *De Cometis* of 1619, and his *Hyperaspistes* of 1625.

In the first edition (1596) of *Mysterium Cosmographicum* Kepler had related planetary orbits to nested regular polyhedra; in the second edition he tries to reconcile these results with his *Harmonice Mundi* (1619), where he used harmonic ratios to produce planetary parameters. In *De Cometis* he treats Halley's Comet as it appeared in September 1607, as well as the three comets of 1618; among other things, he endeavors to determine their motion, assuming that their paths are rectilinear. *Hyperaspistes* is a vehement polemic defending Brahe (d. 1601) against Chiaramonti, who in *Anti-Tycho*, a contribution to the controversy about the comets of 1618, had attacked Brahe's contention that comets are supralunar.

The Latin texts of these works are printed without translation, but followed by summaries and scanty notes and comments in German.

A. Aaboe (New Haven, Conn.)

Vekerdi, László 3337

The discovery of pre-Euclidean mathematics. (Hungarian)
Magyar Tud. Akad. Mat. Fiz. Oszt. Közl. **13** (1963), 133–150.

A brief survey of the discovery of the Greek mathematics of the 6th and 5th centuries B.C., centered on the problem of the so-called "geometrical algebra" of the second book of the *Elements*. It is suggested that the well-known interpretations of O. Neugebauer and B. L. van der Waerden are inspired partly by modern patterns of thought, and that the Greek "geometrical algebra" is, as H. G. Zeuthen already considered it, a simple tool of the Greek "synthetic" geometry.

Á. Szabó (Budapest)

Vekerdi, László 3338

Infinitesimal methods in Pascal's mathematics. (Hungarian)
Magyar Tud. Akad. Mat. Fiz. Oszt. Közl. **13** (1963), 269–285.

Pascal's infinitesimal method in the *Traité des sinus du quart de cercle* is discussed, and it is suggested that it may be an application of the method of indivisibles on infinitesimal concepts of the antique exhaustion method. Analogies to Descartes' method for the calculation of the area of the cycloid are discussed.

Á. Szabó (Budapest)

Boyer, Carl B. 3339

Pascal: The man and the mathematician.
Scripta Math. **26**, 283–307 (1963).

A critical account of Pascal's contributions to mathematics and their relations to previous results and the work of his contemporaries.

O. Ore (New Haven, Conn.)

upont, Pascal 3340
[illegible]same storico-critico del contributo di d'Alembert, Eulero, Poinsot, Poncelet ed altri al concetto dell'asse istantaneo di rotazione nei moti rigidi con un punto fisso.
Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 537–572.
n analysis, in terms of vectors, of instantaneous axes of otation, beginning with D'Alembert's work on the utation of the Earth's axis. Besides the authors mentioned n the title, the studies of Burali-Forti, Marcolongo, and thers in rigid rotating systems are also briefly considered.
G. Huxley (Belfast)

upont, Pascal 3341
Il centro istantaneo di rotazione, nei moti rigidi piani, dal punto di vista storico, critico, applicativo.
Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 331–354.
succinct study of centres of rotation in moving rigid lane systems, beginning with Descartes. The work of ernoulli, Cauchy, Chasles, and others on the subject is onsidered, and there is a neat treatment of stationary oints in rotating squares. The author ends by claiming or instantaneous centres of rotation and for centres of elocity a prime position in kinematics, statics, and nechanics.
G. Huxley (Belfast)

ryde, Matthew M. 3342
Waclaw Sierpiński—mathematician.
Scripta Math. **27**, 105–111 (1964).
n account of the professional life of Sierpiński in elebration of his eightieth birthday. Although there is no ibliography, references to his most important contribuions are mentioned in the text.

hevalley, Claude 3343
Emil Artin [1898–1962].
Bull. Soc. Math. France **92** (1964), 1–10.
n account of Artin's professional career, together with a escription of his most significant contributions. A bibliography, including unpublished lecture notes, is appended.

uraux, Werner 3344
Wilhelm Blaschkes Leben und Werk.
Mitt. Math. Ges. Hamburg **9**, no. 2, 24–40 (1963).
n account of Blaschke's career and principal contribuions. No bibliography is given.

ulliksen, Harold 3345
Samuel Stanley Wilks, 1906–1964.
Psychometrika **29** (1964), 103–104. (1 *plate*)
brief account of the professional career of Wilks. There no bibliography.

ibliography of papers of A. N. Kolmogorov 3346
published in [illegible]–1962. (Russian)
Uspehi Mat. Nauk **18** (1963), no. 5 (113), 121–123.

LOGIC AND FOUNDATIONS

Denjoy, Arnaud 3352
Rapports logiques associés, pour l'inclusion ou l'exclusion, vis-à-vis de p classes d'éléments dans un même espace.
C. R. Acad. Sci. Paris **257** (1963), 2594–2596.
Author's summary: "Les catégories définies par les systèmes de rapports logiques sont figurées, avec les notations de l'algèbre élémentaire, par des formules où chaque variable désigne concurremment un ensemble et sa fonction caractéristique."

Denjoy, Arnaud 3353
Catégories définies par l'association de rapports logiques d'inclusion ou d'exclusion, vis-à-vis de p classes d'éléments dans un même espace.
C. R. Acad. Sci. Paris **258** (1964), 765–767.
Author's summary: "Compléments à la Note précédente [#3352] pour en rectifier certains points et mener l'étude à son terme."

Rose, Alan 3354

Note sur la formalisation de calculs propositionnels polyvalents à foncteurs variables.

C. R. Acad. Sci. Paris **259** (1964), 967–968.

The author considers the problem of deriving, from a given axiomatisation of an M-valued propositional calculus without variable functors (variables for one-place functions from propositions to propositions), an axiomatisation of the corresponding calculus with variable functors. He has already obtained a result of this kind [same C. R. **258** (1964), 1951–1953; MR **28** #2967] which generalises a result of Rosser and Turquette [J. B. Rosser and A. R. Turquette, *Many-valued logics*, North-Holland, Amsterdam, 1951; MR **14**, 526]. It is assumed here that the (original) calculus is functionally complete [ibid., p. 13] and that its axiomatisation includes both a rule of substitution and the analogue of modus ponens. An axiomatisation of the extended calculus is obtained by modifying the rule of substitution (so as to allow substitution for variable functors) and adding a single new axiom. That a provable formula is assertable follows directly from an examination of the new axiom and the modified rule. Functional completeness ensures the availability of certain constant propositional functions, previously used by the author and Rosser and Turquette. Then, being given an assertable formula P of the extended calculus, there is indicated a method of obtaining a finite sequence of assertable formulae such that: (i) the first of them is P, (ii) the last, Q, contains no occurrences of variable functors, and (iii) each can be deduced from its predecessor in the extended axiomatisation. Now, since U is assertable, it can be deduced in the original axiomatisation, and thus one obtains, in a straightforward way, a proof of P in the new axiomatisation. *M. J. Wicks* (Singapore)

Saito, Setsuo 3355

Truth value assignment in predicate calculus of first order.

Notre Dame J. Formal Logic 4 (1963), 216–223.

A decision procedure is proposed for testing validity and consistency of formulas of the restricted predicate calculus. The procedure appears to be an extension of a well-known decision method applied to sentential calculus and is closely related to the use of semantic tableaux developed by E. W. Beth.

E. J. Cogan (Bronxville, N.Y.)

Maehara, Shoji 3356

On the interpolation theorem of Craig. (Japanese)

Sûgaku **12** (1960/61), 235–237.

This paper is an explanatory remark on the interpolation theorem of Craig in connection with a theorem of Beth [Beth, Nederl. Akad. Wetensch. Proc. Ser. A **56** (1953), 330–339; MR **15**, 385] and Gentzen's principal theorem for LK. As an example of possible applications of the interpolation theorem of Craig, the author gives a proof of Beth's theorem by it. An outline of a proof of the interpolation theorem by Gentzen's principal theorem for LK is also added. *K. Ono* (Nagoya)

Ackermann, Wilhelm 3357

Grundgedanken einer typenfreien Logik.

Essays on the foundations of mathematics, pp. 143–155. *Magnes Press, Hebrew Univ., Jerusalem*, 1961.

Es werden typenfreie formale Systeme besprochen, in denen das Komprehensionsaxiom uneingeschränkt gilt, aber das tertium non datur nicht allgemein herleitbar ist. Ein typenfreies System Σ_1, in dem sich die klassische Zahlentheorie und die verzweigte Analysis entwickeln lassen, ist als widerspruchsfrei bekannt [der Verfasser, Math. Z. **57** (1953), 155–166; MR **14**, 834; der Referent, Math. Ann. **125** (1953), 394–400; MR **15**, 386]. Der Nachteil dieses Systems, keine eigentliche Implikationsbeziehung zu enthalten und kein Deduktionstheorem zu besitzen, wird durch Einführung einer fiktiven Beweisbarkeit in einer nachweisbar widerspruchsfreien Erweiterung Σ_2 überwunden [der Referent, Math. Z. **61** (1954), 160–179; MR **16**, 662]. Um gewisse Härten in der Interpretation zu vermeiden, wie sie für Σ_2 bestehen, führt der Verfasser ein im wesentlichen äquivalentes System Σ_3 ein, das eine formal festgelegte Folgerungsbeziehung $U \vdash B$ (ist U beweisbar, so auch B) enthält. Schließlich werden die Grundgedanken für ein weiteres typenfreies System entwickelt, dem interpretationsmäßig ein schärferer Standpunkt zugrundegelegt ist. Es wird nämlich von einer sinnvollen Formel verlangt, daß sie keine sinnlosen Bestandteile enthält, wobei eine Formel U als sinnlos anzusehen ist, wenn sowohl U als auch $\neg U$ sich widersprechende Konsequenzen hat. In diesem System, das vermutlich als widerspruchsfrei nachgewiesen werden kann, läßt sich eine Art Zahlentheorie entwickeln, die jedoch nicht die klassische ist. In einer Erweiterung dieses Systems kann man die klassische Zahlentheorie und weitere Teile der klassischen Mathematik darstellen [der Verfasser, Arch. Math. Logik Grundlagenforsch. **5** (1960/1961), 96–111]. Ein relativer Widerspruchsfreiheitsbeweis des erweiterten Systems unter Bezugnahme auf die axiomatische Mengenlehre wird als wünschenswert angesehen. *K. Schütte* (Kiel)

Rasiowa, H. 3358

A generalization of a formalized theory of fields of sets on non-classical logics.

Rozprawy Mat. **42** (1964), 30 pp.

Let $\mathscr{L}$ be a propositional calculus containing among its binary and unary propositional connectives the signs for disjunction, conjunction and implication, and containing among its theorems all theorems of positive logic. ($\mathscr{L}$ can be, e.g., the classical, intuitionistic, minimal, positive or modal S4 propositional calculus.) With $\mathscr{L}$ a corresponding class of abstract algebras $\mathscr{A}$ ("$\mathscr{L}$-algebras") is associated. Also, with $\mathscr{L}$ a corresponding predicate calculus $\mathscr{L}^*$ of the second order is associated (containing as primitive signs the propositional connectives of $\mathscr{L}$, individual and set variables, quantifiers binding such variables, signs for the identity of individuals and for the equality and inclusion of sets, signs for binary and unary operations on sets—corresponding to the propositional connectives of $\mathscr{L}$—and signs for the universal set and, in case $\mathscr{L}$ contains a negation sign, for the empty set), with an axiom system characterizing the operations and relations, and with the usual rules of inference.

In case $\mathscr{L}$ is the classical propositional calculus, $\mathscr{L}^*$ can be interpreted as a formalized theory of fields of sets. A formula of $\mathscr{L}^*$ containing no individual variables and no quantifiers binding such variables is a theorem of $\mathscr{L}^*$ if and only if it is a theorem in the elementary formalized theory of Boolean algebras.

In the general case, under some additional suppositions concerning $\mathscr{L}$, an interpretation of the system $\mathscr{L}^*$ is given in terms of a model $\mathfrak{M}$ such that for any formula α of $\mathscr{L}^*$, α is a theorem of $\mathscr{L}^*$ if and only if α is valid in $\mathfrak{M}$. Furthermore, a formula of $\mathscr{L}^*$ of the form $A=B$ or $A \subset B$ is a theorem of $\mathscr{L}^*$ if and only if it is a theorem of the elementary formalized theory of $\mathscr{L}$-algebras based on $\mathscr{L}$-logic, whereas the question remains open whether the same holds for arbitrary formulas of $\mathscr{L}^*$ containing no individual variables and no quantifiers binding such variables. *V. Devidé* (Zagreb)

Moreno, Alberto 3359

Propositional logic in Juan de Santo Tomás. (Spanish)

Notre Dame J. Formal Logic 4 (1963), 113–134.

This is an analysis of some of the work of John of St. Thomas (1589–1644) from the point of view of symbolic logic. His view of simple and compound propositions is explained, as are his notions of consequence and argumentation. Negation, disjunction, and conjunction emerge from his work as connectives, while implications of various sorts are, for him, relations among statements. Among his rules of argumentation a substantial number of inference rules available in classical sentence calculi are to be found. Relevant passages from the original Latin text are supplied in notes. *E. J. Cogan* (Bronxville, N.Y.)

Massey, Gerald J. 3360

Note on Copi's system.

Notre Dame J. Formal Logic 4 (1963), 140–141.

The author argues that a proof in the first edition of the reviewer's *Symbolic logic* [Macmillan, New York, 1954; MR 17, 223] is fallacious. The proof in question is intended to establish that the nineteen elementary valid argument forms (of Chapter 3) supplemented by the principles of conditional proof and indirect proof (of Chapter 3) provide a complete system of truth functional logic. The author agrees that the nineteen forms augmented by the strengthened rule of conditional proof (of Chapter 4) is proved complete by the argument of the text, but objects that in Chapter 3 the conditional proof of a formula nowhere contains the formula itself as a whole line, thus making the argument of the text inapplicable. The author is careful to state that his objection is not to the conclusion drawn in the text, which "remains an open question", but to the proof offered in the text. His objection seems to be correct to the present reviewer. (A simpler objection would turn on the fact that the argument in the text makes no reference to the rule of indirect proof, although the text admits that that rule serves to strengthen the proof apparatus consisting of the nineteen forms plus the "weak" conditional proof rule.)

I. M. Copi (Ann Arbor, Mich.)

Canty, John Thomas 3361

Completeness of Copi's method of deduction.

Notre Dame J. Formal Logic 4 (1963), 142–144.

The author settles the open question pointed out by Massey in the note reviewed above [#3360]. The author's proof turns not at all on conditional proof, but entirely on the nineteen forms, plus the rule of indirect proof (IP). Using only the nineteen forms the author proves the validity of a lemma: $q \vee (p \cdot -p) \cdot r .\therefore. q$. Then, using the rule of indirect proof, he proves his Theorem 1: Corresponding to every derived rule which can be demonstrated in RS there is an argument which can be proved valid by Copi's method of deduction (CMD). His proof can be described as follows. For any derived rule $P_1, \cdots, P_n \vdash Q$ of RS, by the deduction theorem there is a demonstration in RS that $\vdash P \supset Q$, where P is the conjunction of $P_1, \cdots, P_n$. Now it is obvious that by CMD a formal proof of validity can be constructed for the argument $P_1, \cdots, P_n, -Q \therefore N$, where N is the disjunctive normal form of the wff $P \cdot -Q$. By the analyticity of RS, $P \supset Q$ is a tautology, hence $P \cdot -Q$ is a contradiction, and every disjunct of N contains a contradiction. Hence by iterated uses of the lemma we obtain by CMD a formal proof of a contradiction from $P_1, \cdots, P_n, -Q$. Now by the rule IP the validity of the argument $P_1, \cdots, P_n \therefore Q$ is proved valid by CMD. Now the completeness of CMD follows from the deductive completeness of RS which contains a derived rule $P_1, \cdots, P_n \vdash Q$ corresponding to any argument $P_1, \cdots, P_n \therefore Q$ that can be proved valid by the use of truth tables. *I. M. Copi* (Ann Arbor, Mich.)

Nagornyĭ, N. M. 3362

On realizable and fulfillable logical-arithmetical formulae. (Russian)

Dokl. Akad. Nauk SSSR 157 (1964), 529–531.

The author proposes a definition of realizability which differs from the original one of Kleene [J. Symbolic Logic 10 (1945), 109–124; MR 7, 406] in some details; it is based on that of Šanin [Trudy Mat. Inst. Steklov. 43 (1955); MR 19, 4]. The object, if any, which realizes a formula P is a partial recursive function or an ordered pair; with it is associated an index (*zapis*, also translatable as "record", "transcription", etc.) which is its Gödel number in some fixed Gödel numeration. If P is a prime formula $T=S$, where T and S are constant terms, the realization, if any, of P is a binary general recursive function R such that $R(m,n)=0$ if and only if $m=n$; and this realizes P if and only if T and S have the same numerical value. If P is compound, the realization, if any, of P is determined in terms of the indices of the major components of P. The author then defines a second notion of fulfillability (*osupolnenie*) by an inductive definition of the same structure except that "realization" is replaced by "fulfillment" and the index of a fulfillment is always (if it exists at all) the number 0. The author states without proof the following two theorems: (1) If constructive logic is used, then a formula P has a realization if and only if it has a fulfillment; (2) If classical logic is used, then the class H of those formulas for which realizability and fulfillability are equivalent cannot be recognized by any algorithm. *H. B. Curry* (University Park, Pa.)

Fuhrken, G. 3363

Skolem-type normal forms for first-order languages with a generalized quantifier.

Fund. Math. 54 (1964), 291–302.

The author considers a language (with denumerably many non-logical constants) obtained from the first-order language by adjoining to it a new quantifier Q. Each ordinal α determines an interpretation L_α of the language

under which the usual connectives and the quantifiers $\wedge$, $\vee$ have the ordinary meaning, whereas $QxFx$ means: there are at least $\aleph_\alpha$ elements satisfying Fx.

Let V_α be the set of formulas which are identically true in the interpretation L_α. The main results of the paper are: (1) If $\aleph_\alpha$ is regular, then $V_1 \subseteq V_\alpha$; (2) $V_\alpha \subseteq V_0$ for every α.

In order to obtain these results the author introduces two "normal forms" for sets of formulas. One of them is used when $\alpha = \beta + 1$ and the other when α is a limit number. The first normal form for a set Σ of formulas is a set Σ^* of first-order formulas (without the quantifier Q) containing two additional predicates, a unary predicate U and a ternary predicate F. The set Σ^* has the property that a relational system $\mathfrak{A}$ of power $\aleph_{\beta+1}$ is a model of Σ if and only if there are a set X (an interpretation of U) and a ternary relation Y (an interpretation of F) such that the relational system $(\mathfrak{A}, X, Y)$ is a model of $\Sigma^* \cup \{QxUx\}$. The word "model" refers, of course, to the interpretation L_α of the logical constants. The idea behind the construction of Σ^* is that U is an auxiliary set of power $\aleph_\beta$, and sentences of the form $QxHx$ are replaced everywhere by sentences stating that there is a one-one mapping of the universe into the set $\{x : Hx\}$; furthermore, one assures (by adding suitable sentences to Σ^*) that for each sentence of the form $QxHx$ occurring as a part of a formula in Σ either the universe can be mapped in one-one way into $\{x : Hx\}$ or the set $\{x : Hx\}$ can be so mapped into $\{x : Ux\}$.

The second normal form is based on a similar principle.

Theorems on normal forms jointly with results of Vaught on Skolem-Löwenheim forms for two cardinals [cf. R. L. Vaught, Bull. Amer. Math. Soc. **69** (1963), 299–313; MR **26** #4912] yield results (1) and (2) stated at the beginning. Another important corollary is the compactness theorem for L_1 which states that a set Σ of formulas is satisfiable (under the interpretation L_1 of logical constants) if and only if every finite subset of Σ is satisfiable.

In addition to these results, the paper lists a couple of theorems on ordinals α, β for which the inequality $V_\alpha - V_\beta \neq 0$ holds. Finally, the author formulates some open problems concerning conditions under which $V_\alpha = V_\beta$, respectively, $V_\alpha \subseteq V_\beta$. *A. Mostowski* (Warsaw)

Vaught, R. L. 3364

The completeness of logic with the added quantifier "there are uncountably many".

Fund. Math. **54** (1964), 303–304.

Using results of G. Fuhrken [#3363], the author shows that the set V_1 is recursively enumerable. More generally, if S is a recursively enumerable set of formulas, then so is the set of (semantically defined) consequences of S, logical constants being interpreted according to L_1.

The author notes that the set V_1 is defined in set theory. If one limits the notion of "sets" used in the definition of V_1 to constructible sets, one obtains a definition of another possible set V_1^c. The author shows, however, that the equation $V_1 = V_1^c$ is provable in the Zermelo-Fraenkel set theory. Thus one can always eliminate the generalized continuum hypothesis and more generally, the axiom of constructibility from a proof of a theorem saying that a particular formula F belongs to V_1. *A. Mostowski* (Warsaw)

Pi Calleja, Pedro 33[illegible]

Formalization of the Russell counter-paradox. (Spanish)

Math. Notae **19** (1964), 147–151.

The author makes a few remarks about Russell's parado[x] emphasizing the analogous problem of a catalogue listi[ng] all those catalogues which do not list themselves. He al[so] refers to the resolution of the paradox in axiomatic s[et] theory. No new slant on the paradoxes is offered. *E. Mendelson* (Flushing, N.Y.)

Hintikka, Jaakko 336[6]

The modes of modality.

Acta Philos. Fenn. Fasc. **16** (1963), 65–81.

A non-technical exposition of the author's theory o[f] model systems as a unifying concept in the study o[f] modal logics; somewhat more extensive than the author's previous sketch [Theoria (Lund) **27** (1961), 119–128; MR **25** #2953]. *E. Mendelson* (Flushing, N.Y.)

Sacks, Gerald E. 336[7]

The recursively enumerable degrees are dense.

Ann. of Math. (2) **80** (1964), 300–312.

The author shows that, given recursively enumerable (RE) degrees **b** and **c** with **b** < **c**, there is an RE degree **d** with **b** < **d** < **c**. (The case **b** = **0** had been previously proved by Muchnik and Friedberg.) Given RE sets B and C of degrees **b** and **c**, respectively, the author constructs an RE set D of degree **d**. The set B is "copied" in D. In addition, a partial copy of C is made in D for each i to insure that $D \neq \{i\}^B$. A complete copy would insure this, since C is not recursive in B; but only a partial copy must be made, since we want $C \neq \{e\}^D$. As usual, a priority scheme is set up between these requirements. A difficulty is that the requirement $C \neq \{e\}^D$ may interfere infinitely often with a lower priority requirement $D \neq \{i\}^B$. However, this can happen only when $\{e\}^C$ is not total; the author then says that e is unstable. The construction insures that for given i, there will be infinitely many stages at which no unstable $e < i$ is preventing us from making the ith copy of C in D; so we can achieve $D \neq \{i\}^B$. A tedious but straightforward argument then shows that D is recursive in C. *J. R. Shoenfield* (Durham, N.C.)

Sacks, Gerald E. 3368

A maximal set which is not complete.

Michigan Math. J. **11** (1964), 193–205.

The author shows that if **c** is a degree such that $\mathbf{0} < \mathbf{c} \leq \mathbf{0}'$, then there is a degree **b** containing a maximal recursively enumerable set such that $\mathbf{c} \not\leq \mathbf{b}$ (so that $\mathbf{b} \neq \mathbf{0}'$). Given a set C of degree **c**, the author constructs a maximal recursively enumerable set M of degree **b** by combining Friedberg's construction of a maximal set with standard priority methods for insuring that M is not recursive in C. Difficulties arise because a requirement for making M maximal may necessitate putting infinitely many numbers in M, thus interfering with a lower priority requirement infinitely often. This difficulty is surmounted by methods previously developed by the author [#3367 above]. *J. R. Shoenfield* (Durham, N.C.)

Mendelson, Elliott 3369

On some recent criticism of Church's Thesis.

Notre Dame J. Formal Logic **4** (1963), 201–205.

The author rejects three recent arguments directed against Church's thesis. The first, by J. Porte, is found to confuse "effective computability" with "human computability". The second, by R. Péter, interprets Kleene's definition of recursive function more narrowly than is intended in the statement of Church's thesis. And the third argument by L. Kalmar is found to contain the tacit assumption that the class of proofs in arbitrary consistent extensions of a given first-order theory p is effectively enumerable. Church's thesis does not lead to a contradiction, but merely implies the falsity of this assumption.

D. L. Kreider (Hanover, N.H.)

Hermes, Hans 3370

Unentscheidbarkeit der Arithmetik.

Math.-Phys. Semesterber. 11 (1964), 20–34.

This is a brief but very clear exposition of matters connected with the title. It contains a condensed explanation of a Turing machine and a sketch of the proof by way of the undecidability of semi-Thue systems. For details the author refers to his book [*Aufzählbarkeit, Entscheidbarkeit, Berechenbarkeit*, Springer, Berlin, 1961; MR 26 #1252]. *H. B. Curry* (University Park, Pa.)

Vučković, Vladeta 3371

On some possibilities in the foundations of recursive arithmetics of words. (Serbo-Croatian summary)

Glasnik Mat.-Fiz. Astronom. Društvo Mat. Fiz. Hrvatske Ser. II 17 (1962), 145–157 (1963).

The author generalises his previous work on multiply successor arithmetics to systems whose "numerals" are finite strings of letters of an alphabet a_ξ, $\xi \in I$. It is shown that even when no conditions are imposed upon the alphabet (other than that the letters are distinct and one of them is distinguished), the characteristic function for word equality is primitive recursive and the analogue of induction is provable. If the index set I is a semi-group, the associative law for addition is provable, but the general associative law for linear operations requires the semi-group to be commutative. When I is a group (with neutral element 0, and $-\xi$ the inverse of ξ), if a_0 now denotes the empty word, so that the alphabet is a_ξ, $\xi \in I-\{0\}$, and if we impose the axioms

$$a_{-\xi}a_\xi = a_\xi a_{-\xi} = a_0$$

for all $\xi \in I-\{0\}$, and define $-X$ by

$$-a_0 = a_0, \qquad -(a_\xi X) = a_{-\xi}+(-X), \qquad \xi \in I-\{0\},$$

then $X = -A$ is the solution of each of the equations

$$X+A = a_0, \qquad A+X = a_0.$$

Péter, Rózsa 3372

Über die Primitiv-Rekursivität einiger den Aufbau von Formeln charakterisierenden Wortfunktionen.

Acta Math. Acad. Sci. Hungar. 14 (1963), 149–172.

Formulas of the propositional calculus are treated as words on an appropriate alphabet, and the notion of primitive recursive word-function is used. The step-by-step inward decomposition of a formula into successive components is systematized by means of a Kantorovich graph, the nodes of which are indexed in a simple fashion by words on two fixed letters. The graph of a formula is shown to depend primitive recursively on the formula. Let $\mathrm{Pos}(x, y) \equiv [y$ is the index of a node of the graph of a formula x, and y represents a positive component of $x]$, and let $\mathrm{Neg}(x, y)$ be defined similarly for negative components. Then Pos and Neg are primitive recursive. There is a primitive recursive function with primitive recursive inverse which for each formula maps its Łukasiewicz parenthesis-free notation onto its Pawlak parenthesis-free notation. *P. Axt* (E. Lansing, Mich.)

Markov chains and intuitionism. III. Note on continuous functions with an application to Markov chains.

Nederl. Akad. Wetensch. Proc. Ser. A 67 = *Indag. Math.* 26 (1964), 256–261.

Part II appeared in same Proc. 66 (1963), 275–281 [MR 27 #6304]. The limit properties of continuous functions defined in an interval at the end points of the interval are considered. The following intuitionistic result has no classical counterpart: If $f(t)$ is a function defined for all real numbers t such that $(t \nless a) \vee (t<a)$ and if $\lim_{t\downarrow x} f(t)$ exists for every x, then we have $\lim_{t\uparrow a} f(t) = \lim_{t\downarrow a} f(t)$. These results are motivated by a theorem of Doob's on Markov chains.

Žuravlev, Ju. I. 3374

An estimate of complexity of local algorithms for certain extremal properties on finite sets. (Russian)

Dokl. Akad. Nauk SSSR 158 (1964), 1018–1021.

This paper concerns algorithms for deciding for finite sets of a family $\mathfrak{M}$ whether or not predicates of a given class P are true. Such an algorithm is said to be local if its procedure in making a decision for a set $\mathfrak{A}$ is conditioned by its decision for sets $\mathfrak{B}$ in $\mathfrak{M}$ in a neighborhood of $\mathfrak{A}$, where neighborhoods are interpreted distinctly in special situations. Among special local algorithms are those for obtaining minimal disjunctive normal forms and those for constructing minimal paths in lattice graphs. The results of the paper give estimates of complexity of local algorithms in terms of the sizes of neighborhoods and of the cardinal number of the class P of predicates.

E. J. Cogan (Bronxville, N.Y.)

Rutledge, J. D. 3375

On Ianov's program schemata.

J. Assoc. Comput. Mach. 11 (1964), 1–9.

Ju. I. Janov's program schemata [Problemy Kibernet. 1 (1958), 75–127; MR 24 #B1735; for a leisurely English exposition see the reviewer's article in *Logik und Logikkalkül*, pp. 159–178, Verlag Karl Alber, Freiburg, 1962] are strings of symbols that abstractly characterize the sequential and control properties of computer programs (without algebraically inessential details). Alternatively, Janov gave such characterizations in matrix form. In terms of and for such schemata, Janov devised constructive equivalence criteria—"equivalence" in what the author rightly calls a "very strong" sense.

The author aims at expounding Janov's results in the context of a judiciously revamped formal apparatus of his

own, and he presents inter alia an algorithm for the equivalence problem as conceived and solved by Janov. Pointing out the proximity and relevance of such considerations to the equivalence problem for finite automata, he also specifies a procedure for generating all members of an equivalence class of schemata, given one member.

{It appears, from a review, that some of the author's results, in particular, the tie-up with finite-automata theory, were independently obtained by S. Igarashi [J. Information Processing Soc. Japan 3 (1962), 66–72; MR 28 #4979].} *E. M. Fels* (Munich)

Elgot, C. C.; Rutledge, J. D. 3376

RS-machines with almost blank tape.

J. Assoc. Comput. Mach. **11** (1964), 313–337.

Authors' summary: "Finite automata which communicate with counters or with tapes on a single-letter alphabet with end mark are studied. A typical machine system studied here consists of a family of machines; the finite automaton part of each of the machines is identical; each machine has one reset counter (almost blank loop tape) and one non-reset counter (almost blank straight tape); the first counter counts up to a, say, and the second counts running up to a, b, respectively. The system "accepts" those pairs (a, b) such that the (a, b)-machine eventually halts when started in standard position. Thus the system defines a binary relation on natural numbers. Some solvability and unsolvability results are obtained concerning the emptiness of the set accepted by a system or the emptiness of the intersection of the sets accepted by two or more systems. Some of the theorems strengthen results of Rabin and Scott [IBM J. Res. Develop. 3 (1959), 114–125; MR 21 #2559]. It is shown for a certain class of systems that the relations defined by them are exactly the same as those definable in the elementary theory of addition of natural numbers. For another class of systems it is shown that an intersection problem is equivalent to Hilbert's tenth problem."

Frey, T. 3377

Über die Konstruktion nichtvollständiger Automaten.

Acta Math. Acad. Sci. Hungar. **15** (1964), 375–381.

Let F^* be a set of words (over a finite alphabet) which contains u if it contains uv. Two incomplete Moore sequential machines A and B, with start states, are called F^* equivalent if, for each word in F^* as input, the outputs from A and B coincide. Using standard techniques, the author constructs for each machine defined over F^* a smallest state F^* equivalent machine.

S. Ginsburg (Van Nuys, Calif.)

Frey, T. 3378

Über die Konstruktion endlicher Automaten.

Acta Math. Acad. Sci. Hungar. **15** (1964), 383–398.

Regular sets are here given by automata. The author considers functions f of regular sets which yield regular sets. In addition, he seeks constructions realizing f which yield reduced (i.e., minimal state) automata if the original automata are reduced. All the functions discussed, which include union, intersection, star, and initial subwords among others, are already known to preserve regular sets (many, in fact, with the same constructions in the paper). The only new results are those relating to when the constructed automaton is reduced.

La Menza, Francisco 3380

On the foundations of arithmetic. (Spanish)

Math. Notae **19** (1964), 171–177.

A few deductions are carried out, based on Dedekind's definition of finite set; for example, the union of two finite sets is shown to be finite. However, in trying to prove the trichotomy law for finite sets, the author takes as obvious a theorem which is actually equivalent to the trichotomy law for arbitrary sets.

E. Mendelson (Flushing, N.Y.)

Ono, Katuzi 3381

New formulation of the axiom of choice by making use of the comprehension operator.

Nagoya Math. J. **23** (1963), 53–71.

Es handelt sich um Formalisierungen der Mengenlehre im Rahmen der gewöhnlichen Prädikatenlogik mit der binären Relation $\in$ als einziger Grundrelation. Die Gleichheit $=$ und die Identität $\Box$ sind folgendermaßen definiert: $x = y \equiv \forall z\,(z \in x \leftrightarrow z \in y)$, $x \Box y \equiv \forall t\,(x \in t \leftrightarrow y \in t)$. Jede Menge r bestimmt in natürlicher Weise zwei binäre Relationen r (bezüglich der Gleichheit) und $\underset{\Box}{r}$ (bezüglich der Identität). Durch den Komprehensionsoperator wird aus einer binärer Relation Γ eine binäre Relation (Γ) gebildet: $x(\Gamma)y \equiv \forall s\,(s \in x \leftrightarrow s\Gamma y)$. Für das Produkt $\Gamma\Delta$ aus zwei binären Relationen Γ und Δ gilt: $x\Gamma\Delta y \equiv \exists z\,(x\Gamma z \wedge z\Delta y)$. In dieser Symbolik läßt sich eine strenge Fassung des Auswahlaxioms folgendermaßen formulieren: (A) $x \in y \to y \ni (\eta)y$. Dabei ist η eine spezielle binäre Relation. Zwei verschiedene schwache Fassungen des Auswahlaxioms lauten: (B) $\exists r \forall xy\,(x \in y \in m \to y \ni (\underset{\Box}{r})y)$, (C) $\exists r \forall xy\,(x \in y \in m \to y \ni (r)y)$. Aus dem Axiom (C) und der Voraussetzung, daß es zu jeder Menge s eine Einheitsmenge $\{s\}$ gibt, folgt das Extensionalitätsaxiom. (Hiermit fällt die Gleichheit mit der Identität zusammen.) Der Verfasser untersucht die Beziehungen zwischen den verschiedenen Auswahlaxiomen (A)–(C) und gewissen Verallgemeinerungen dieser Axiome im Rahmen seiner Objekttheorien OF [dasselbe J. 22 (1963), 119–167; MR

27 #5669] und OZ [ibid. 29 (1962), 105–168; MR 26 #36], die nur je ein Axiom haben, das jeweils unter Bezugnahme auf eine Satellitenrelation formuliert ist. Fügt man zu dem Axiom von OF das Auswahlaxiom (C) hinzu (wobei die Satellitenrelation von OF durch die einfachere Satellitenrelation von OZ ersetzt werden kann), so ergibt sich eine Theorie, die nach Angabe des Verfassers mit der Mengentheorie von Fraenkel (unter Anschluß des Fundierungsaxioms) äquivalent ist. *K. Schütte* (Kiel)

Kurepa, G. [Kurepa, Đuro] 3382

On rank-decreasing functions.

Essays on the foundations of mathematics, pp. 248–253. *Magnes Press, Hebrew Univ., Jerusalem*, 1961.

The author considers any partially ordered set B in which every chain is well-ordered and extends the theory of regressive functions for such sets [cf. W. Neumer, Math. Z. 54 (1951), 254–261; MR 13, 331; the reviewer, Acta Sci. Math. (Szeged) 17 (1956), 139–142; MR 18, 551; G. Kurepa, Z. Math. Logik Grundlagen Math. 4 (1958), 148–156; MR 20 #4499; R. Ricabarra, Rev. Mat. Cuyana 2 (1956), 1–27; MR 22 #1518]. Any B determines a well-defined sequence of mutually disjoint sets R_0B, R_1B, $\cdots$, $R_\alpha B$, $\cdots$, where R_0X denotes the set of the initial elements of X and where $R_\alpha B=R_0(B-\bigcup_{\xi<\alpha}R_\xi B)$. For each $x\in B$ one has a well-determined ordinal number γx such that $R_{\gamma x}$ contains x. Let $\gamma M=(\gamma x : x\in M)$ for each $M\subseteq B$. The set γB is an initial section of ordinal numbers. The ordinal type of γB is supposed to be an initial number ω_α such that $\mathrm{cf}(\alpha)>0$. A set $M\subseteq B$ is said to be a stationary set in B, provided the set γM has the corresponding property in γB, i.e., γM intersects every closed set $\subseteq B$ cofinal to γB. Each function f whose domain D and antidomain fD are parts of B and which satisfies $\gamma fx=\gamma x$ for $x\in D\cap R_0B$ and $\gamma fx<\gamma x$ for $x\in D-R_0B$ is said to be a γ-regressive (or rank-decreasing) function. For a rank-increasing function one has $\gamma x<\gamma fx$ $(x\in D)$. The main results are as follows. If ω_α is a regular initial number and if for every $\beta\in\gamma B$ the cardinal number of $R_\beta B$ is $<\aleph_\alpha$, then for every many-valued rank-increasing function f from B into B such that, for each $x\in B$, the set (fx) of values fx at x is a non-stationary set, the set fB is a non-stationary set (Theorem 3.5). Let, for every $\beta\in\gamma B$, the cardinal number of $R_\beta B<\aleph_{\mathrm{cf}(\alpha)}$. If M is any stationary set in B and if f is any γ-regressive function from M into B, then there exists a stationary set $M_0\subseteq M$ such that $\sup\gamma fM_0<\inf\gamma M_0$ (Theorem 4.2).

Keisler, H. Jerome 3383

Good ideals in fields of sets.

Ann. of Math. (2) 79 (1964), 338–359.

This paper deals with certain Boolean-algebraic properties of ideals in fields of sets, somewhat related to infinite additivity. The results have important applications in model theory, but are also of independent interest.

Let D be a set of sets directed by inclusion (i.e., $(\forall x, y\in D)(\exists z\in D)(z\supseteq x\cup y)$), and let f and g be functions on D with values in the set $S(X)$ of all subsets of X. We write $g\geq f$ if for all $x\in D$, $g(x)\supseteq f(x)$. We say that an ideal I in the field $S(X)$ is D-good if for every monotonic function f on D into I there exists an additive function $g\geq f$ on D into I.

For each ideal I let $G(I)$ be the least cardinal $|D|$ of a directed set D such that I is not D-good, if there is such a D. By Theorem 3.2 (credited to C. C. Chang), if $|Y|=G(I)$, then I is not $S_\omega(Y)$-good, where $S_\omega(Y)$ is the set of all non-void finite subsets of Y. The author's main results are the following. Let $|X|=\alpha$ and let α^+ be the least cardinal greater than α. (A) Assuming $2^\alpha=\alpha^+$, there are 2^{2^α} prime ideals I in $S(X)$ such that $G(I)=\alpha^+$; (B) There are 2^{2^α} prime ideals I in $S(X)$ such that $G(I)=\omega^+$. The paper is concluded with a list of interesting problems, mostly concerned with the function G. *A. Lévy* (Jerusalem)

Keisler, H. Jerome 3384

On cardinalities of ultraproducts.

Bull. Amer. Math. Soc. 70 (1964), 644–647.

This paper answers some unsolved problems of five or six years standing concerning the cardinalities of ultraproducts. The more interesting consequences of these results concern the cardinalities of ultrapowers, and they are stated by the author in Theorem A as follows (D is a nonprincipal ultrafilter over a set I of infinite power λ). (i) If α is infinite and D is not countably complete, then $\alpha^I/D=(\alpha^I/D)^\omega$. (ii) For any α, γ, and D, $(\alpha^\gamma)^I/D\geq(\alpha^I/D)^\gamma$. (iii) If D is uniform, then $(\alpha^{(\lambda)})^I/D=(\alpha^I/D)^\lambda=\alpha^\lambda$, where $\alpha^{(\lambda)}=\sum_{\beta<\lambda}\alpha^\beta$. Each part of Theorem A has a corresponding generalization (given in Theorem 2.2) to ultraproducts $\prod_{i\in I}\alpha_i/D$. The author observes that the proofs of these theorems can be made uniform by introducing the notion of (β,γ)-regular ultrafilters and proving a result (Theorem 2.1) about them. Essentially, Theorems A and 2.2 follow from Theorem 2.1 by noticing that (Lemma 1.3) every countably incomplete ultrafilter is (ω,ω)-regular and every uniform ultrafilter is (λ,λ)-regular. Another consequence of Theorem 2.1 concerns the cardinal $\alpha=\prod_{i\in I}n_i^{q(n_i)}/D$, where $\lim_{m\to\infty}q(m)=\infty$. It turns out (Theorem 2.3) that if $\beta=\prod_{i\in I}n_i/D$ is infinite, then $\alpha\geq\beta^\omega$.

Keisler, H. J.; Tarski, A. 3385

From accessible to inaccessible cardinals. Results holding for all accessible cardinal numbers and the problem of their extension to inaccessible ones.

Fund. Math. 53 (1963/64), 225–308.

The authors investigate the classes C_0, C_1, C_2 of all infinite cardinals satisfying the following conditions (a), (b), and (c), respectively: (a) There exists an α-complete field of sets with at most α generators in which some α-complete proper ideal cannot be extended to an α-complete prime ideal; (b) In the field of all subsets of a set of power α every α-complete prime ideal is principal; (c) There exists an α-complete field of sets in which some α-complete proper ideal cannot be extended to an α-complete prime ideal.

It has been known for some time that $\omega\notin C_0\subseteq C_1\subseteq C_2$, and that all accessible cardinals belong to C_0 [P. Erdős and A. Tarski, *Essays on the foundations of mathematics*, pp. 50–82, Magnes Press, Hebrew Univ., Jerusalem, 1961; MR 29 #4695]. It has turned out, contrary to expectations, that a very large class of inaccessible cardinals is a part of C_0. This was first proved by Tarski [Logic, Methodology and Philosophy of Science (Proc. 1960 Internat. Congr.), pp. 125–135, Stanford Univ. Press, Stanford, Calif., 1962; MR 27 #1382], using a metamathematical result of W. P. Hanf [Fund. Math. 53 (1963/64), 309–324; MR 26 #3943].

H. J. Keisler gave a different model-theoretical proof of a similar result concerning the class C_1 [Logic, Methodology and Philosophy of Science (Proc. 1960 Internat. Congr.), pp. 80–86, Stanford Univ. Press, Stanford, Calif., 1962].

The authors give a purely mathematical discussion of the problems involved in (a), (b), and (c) and prove that a very large class of infinite cardinals α possesses the properties (a), (b), and (c).

"Actually we do not know at present any non-denumerable cardinal which is capable of a 'constructive characterization' (in some very general and rather loose sense of the term) and for which we could not prove that it possesses the properties discussed. Nevertheless, the straightforward question whether all cardinals larger than ω possess these properties is still open, and it does not seem very likely that the methods now available will bring forth an answer to this question" (from the introduction of the authors).

The authors define a family of subclasses of C_1 called normal classes and define some "constructively characterised" operations on normal classes (or on sequences of normal classes) such that these operations lead from a class X to a new class Y which includes X. The results concerning the extent of class C_1 consist in establishing induction principles which say that the above operations yield normal classes when applied to normal classes and are based on the theorem that the class of all accessible cardinals is normal. The proofs of these results are given in full in § 1. In § 3, Theorem 3.4, it is proved that C_0 itself is normal and, as a corollary of this, C_0 is a proper part of C_1 unless C_1 contains all non-denumerable cardinals. On the other hand, as an improvement of the results of § 1 it is proved that various "constructively defined" classes of cardinals are included in C_0. Some of the proofs given in § 3 are of sketchy character. The authors mention that they are going to publish a paper considering metamathematical problems exhibiting the same pattern. There they will give much simpler metamathematical proofs for results which imply all the results of § 3.

The authors discuss several mathematical problems exhibiting the same pattern as the problems involved in (a), (b), and (c). Most of these problems can be shown to be equivalent to one of the problems discussed in detail, and so the authors get important corollaries of their results in various branches of mathematics: general set theory, theory of Boolean algebras, theory of measure, group theory, topology and functional analysis. These results can be considered as characterizations of the classes C_0, C_1, C_2 and are proved in §§ 4, 2 and 5, respectively.

The following corollaries of the results give a general survey of the problems and results of the respective sections.

Theorem 4.35: The hypothesis $C = C_0$ implies (and is implied by) each of several statements, e.g.,

(i) For every $\alpha > \omega$ there is an α-complete field of subsets of α which includes $S_\omega(\alpha)$, is α-generated by a set of power α, and in which every α-complete prime ideal (more generally, every α-complete and δ-saturated ideal with $2^\delta < \alpha$) is principal.

Theorem 2.50: The hypothesis $C = C_1$ implies (and is implied by) each of several statements, e.g.,

(i) In every β-complete Boolean algebra every countably complete prime ideal is β-complete.

Theorem 5.12: The hypothesis $C = C_2$ implies (and is implied by) each of several statements, e.g.,

(i) For every α there is a β such that, for every $\gamma \geq \beta$, some α-complete proper ideal in $S(\gamma)$ cannot be extended to any α-complete prime ideal (more generally, to any α-complete and δ-saturated proper ideal with $2^\delta < \alpha$).

These theorems have further corollaries under the assumption that the generalised continuum hypothesis holds. Theorem 2.51 (iii) states that if the generalised continuum hypothesis holds, or at least $[\omega_1, 2^\omega]$ does not contain regular limit cardinals, the hypothesis that every non-denumerable α belongs to C_1 is equivalent to the statement that there is no (countably additive non-trivial) measure on any set.

It is to be mentioned that in some places the authors point out interesting and important unsolved problems; see, e.g., pages 230, 267 and 305. The paper contains complete references on the known results on the topic and restates the most important of them.

Monk, D.; Scott, D. 3386

Additions to some results of Erdős and Tarski.

Fund. Math. 53 (1963/64), 335–343.

The authors prove some results on the topic treated by H. J. Keisler and A. Tarski [#3385].

The relations $T(\alpha, \beta)$, $\bar{R}(\alpha, \beta)$ are defined for infinite α, β. $T(\alpha, \beta)$ holds if and only if the α-product space of a β-termed sequence of discrete two-point topological spaces is α-compact. $\bar{R}(\alpha, \beta)$ holds if and only if in every α-complete field α-generated by at most β elements every α-complete proper ideal can be extended to an α-complete prime ideal. Theorem 1.8 states that $\bar{R}(\alpha, \beta)$ and $T(\alpha, \beta)$ are equivalent unless α is singular and $\alpha = |2^\alpha|$. $C(\alpha)$ is said to hold if the α-product space of an arbitrary sequence of α-compact topological spaces is α-compact. Theorem 1.9 states that $C(\alpha)$ is equivalent to the statement that $T(\alpha, \beta)$ holds for every β. A ramification system is said to be an α-ramification system if it is a system of order α and for every $\xi < \alpha$ the set of all elements of order ξ has power less than α. $Q(\alpha)$ is said to hold if every α-ramification system has a simply ordered subset of type α. Theorem 2.1 states that for every strongly inaccessible α, $Q(\alpha)$ and $T(\alpha, \alpha)$ are equivalent.

In Theorems 3.1 and 3.2 equivalents of $T(\alpha, \beta)$ are given in terms of general set theory. They are called first and second separation principles, respectively.

Doss, Raouf 3388

On Gödel's proof that $V = L$ implies the generalized continuum hypothesis.

Notre Dame J. Formal Logic 4 (1963), 283–287.

The proof mentioned in the title is modified as follows: For a set m of ordinals closed with respect to the operations J_i $(0 \le i < 9)$, K_1, K_2, O known from Gödel's monograph [*The consistency of the continuum hypothesis*, Princeton Univ. Press, Princeton, N.J., 1940; MR 2, 66] and with respect to still one more auxiliary operation O_1, the author defines by transfinite induction a function H on ordinals such that $H(J_i(\langle\alpha, \beta\rangle)) = \mathfrak{F}_i(H(\alpha), H(\beta))$ for $0 < i < 9$ and $H(J_0(\langle\alpha, \beta\rangle)) = H``m \cap J_0(\langle\alpha, \beta\rangle)$. He shows that the relations $F(\alpha) \in F(\beta)$ and $H(\alpha) \in H(\beta)$ are equivalent for $\alpha, \beta \in m$, and similarly for the relations $F(\alpha) = F(\beta)$ and $H(\alpha) = H(\beta)$. If G is an isomorphism from m to an ordinal, then $H(\alpha) = F(G(\alpha))$ for $\alpha \in m$. Proofs of these theorems are brief and quite simple. The author shows that they can replace the rather cumbersome proof given on pp. 54–60 of Gödel's monograph. *A. Mostowski* (Warsaw)

COMBINATORIAL ANALYSIS

Bizley, M. T. L. 3389

A problem in permutations.

Amer. Math. Monthly **70** (1963), 722–730.

The problem in question is the enumeration of the arrangements of m letters and a_i letters A_i, $i = 1, 2, \cdots, n$, such that apart from the M's, no two like letters are together. The problem is solved in two ways and generalized to the case where there are a_i letters A_i, $i = 1, 2, \cdots, n$, and at most b_i of the letters A_i are together. The (multivariable) generating function for the numbers of the latter case is shown to be $[1 - \sum_{i=1}^{n} x_i(1 - x_i^{b_i}) \times (1 - x_i^{b_i+1})^{-1}]^{-1}$. Recurrence relations, multiple sum expressions, and the relation of the symmetrical case (when all of the various kinds of letters are subject to the same restrictions) to the two-pack matching problem are also given. *J. Riordan* (Murray Hill, N.J.)

Classes of geometric designs.

Rend. Mat. e Appl. (5) **23** (1964), 14–21.

Author's introduction: "The purpose of this purely expository paper is to outline some geometric aspects of the theory of (balanced incomplete block) designs. Our discussion falls into two parts which are only loosely connected. In Section 1 we give the basic definitions and discuss the question how the finite projective and affine spaces can be characterised among the more general projective, resolvable, and affine designs. Section 2 deals with finite inversive planes; these form a special class of 3-designs. We shall be mainly interested in the characterisation of the miquelian finite inversive planes, and some results in this direction will be given."

Moon, John W. 3391

A note on "Pattern variants on a square field".

Psychometrika **28** (1963), 93–95.

A k-pattern on an m-by-m square of m^2 like cells is a selection of k cells. Two patterns are equivalent if one can be obtained from the other by a rotation or reflection of the square. The number g_{mk} of inequivalent k-patterns has been found by S. J. Prokhovnik [Psychometrika 24 (1959), 329–341]; here it is formulated in terms of George Pólya's fundamental theorem of enumerative combinatorial analysis. The cycle index is

$$(f_1^{m^2} + 2f_1^m f_2^{m(m-1)/2} + 3f_2^{m^2/2} + 2f_4^{m^2/4})/8 \quad \text{for } m \text{ even},$$

$$(f_1^{m^2} + 4f_1^m f_2^{m(m-1)/2} + f_1 f_2^{(m^2-1)/2} + 2f_1 f_4^{(m^2-1)/4})/8 \quad \text{for } m \text{ odd},$$

and the store enumerator is $1 + x$. It is also noted that the theorem is adapted to other specifications of patterns and equivalence relations; in particular, the patterns on a rectangle whose cells may be marked in two ways, and whose equivalences are specified by the group of reflections of the rectangle, are enumerated. No attention is given to the development of the theorem for numerical results, nor to more complicated equivalences such as that in F. Harary [Pacific J. Math. 8 (1958), 743–755; MR 21 #2598]. *J. Riordan* (Murray Hill, N.J.)

The inverse multiplier for abelian group difference sets.

Canad. J. Math. **16** (1964), 787–796.

The author proves (I) If -1 is a multiplier of a difference set with parameters v, k, λ of an Abelian group G, then v and λ are even and $v = (m/\alpha)[(m+\alpha)^2 - 1]$, $k = m(m+\alpha)$, $\lambda = m\alpha$, where m and α are integers and $m \equiv \alpha + 1$ (2). (II) If 2^{s_1} is the order of the subgroup of element of order 2 of G and if $2^{s_1} < (k/\lambda) + 1$, then -1 is not a multiplier. *H. B. Mann* (Madison, Wis.)

Erdős, P.; Hanani, H. 3394

On a limit theorem in combinatorial analysis.

Publ. Math. Debrecen **10** (1963), 10–13.

Given a set E of positive integers and positive integers k, such that $l \le k \le n$, let $M(k, l, n)$ denote a minimal system of k-tuples such that every l-tuple is contained in at least one k-tuple of the system. Let $m(k, l, n)$ denote a maximal system of the k-tuples such that every l-tuple is contained in at most one set of the system. The number of k-tuples

in these systems is denoted by $\bar{M}(k, l, n)$ and $\bar{m}(k, l, n)$, respectively. Put

$$\mu(k, l, n) = \binom{k}{l}\binom{n}{l}^{-1}\bar{M}(k, l, n),$$

$$\nu(k, l, n) = \binom{k}{l}\binom{n}{l}^{-1}\bar{m}(k, l, n),$$

so that $\nu(k, l, n) \leq 1 \leq \mu(k, l, n)$ with equality only if

$$\binom{k-h}{l-h}\bigg|\binom{n-h}{l-h} \qquad (h = 0, 1, \cdots, l-1).$$

Hanani [see #4161 below] has proved that the equalities hold for $l=2$, $k=3, 4, 5$ and for $l=3$, $k=4$.

Erdős and Rényi [Publ. Math. Debrecen 4 (1956), 398–405; MR 18, 3] have proved that for every k

$$\lim_{n=\infty} \mu(k, 2, n) = \gamma_k \quad \text{and} \quad \lim_{k=\infty} \gamma_k = 1.$$

In the present paper it is proved that

$$\lim_{n=\infty} \mu(k, 2, n) = \lim_{n=\infty} \nu(k, 2, n) = 1 \qquad (k = 2, 3, \cdots),$$

$$\lim_{n=\infty} \mu(p+1, 3, n) = \lim_{n=\infty} \nu(p+1, 3, n) = 1,$$

where p is a power of a prime.

Szász, Gábor 3396

★Introduction to lattice theory.

Third revised and enlarged edition. MS revised by R. Wiegandt; translated by B. Balkay and G. Tóth.

Academic Press, New York-London; Akadémiai Kiadó, Budapest, 1963. 229 *pp*. $8.50.

This English version of Szász's text differs somewhat from the German edition [*Einführung in die Verbandstheorie*, Akadémiai Kiadó, Budapest, 1962; MR **25** #2011]. It has a new tenth chapter on direct and subdirect decompositions not included in the German edition. The bibliography, which is good but not exhaustive, has now 232 entries instead of 198. The added references are mostly to recent papers, some of which are referred to in the revised text.

Some of the new sections included in this edition are on length, the maximum and minimum conditions, irreducible and prime elements of a lattice, complete sublattices of a complete lattice, compact elements, and compactly generated lattices. Some of the problems at the ends of the chapters are new. The titles of the chapters are: (1) Partly ordered sets, (2) Lattices in general, (3) Complete lattices, (4) Distributive and modular lattices, (5) Special subclasses of the class of modular lattices, (6) Boolean algebras, (7) Semimodular lattices, (8) Ideals of lattices, (9) Congruence relations, (10) Direct and subdirect decompositions.

This is a clearly written introductory text from which one can learn painlessly most of the fundamental notions and methods of lattice theory. It is not intended for the specialist or research worker. For the most difficult topics the author refers the reader to the literature. It includes little or nothing about ordered linear spaces or lattice ordered rings, groups, and semigroups.

O. Frink (University Park, Pa.)

Szász, G. [Szász, Gábor] 3397

On independent systems of axioms for lattices.

Publ. Math. Debrecen **10** (1963), 108–115.

Let $L=(L; \cap, \cup)$ be an algebra with two binary operations denoted by $\cap$ and $\cup$, and consider the equations: (1) $(x \cap y) \cap z = x \cap (y \cap z)$; (2) $(x \cup y) \cup z = x \cup (y \cup z)$; (3) $x \cap y = y \cap x$; (4) $x \cup y = y \cup x$; (5) $x \cap (x \cup y) = x$; (6) $x \cup (x \cap y) = x$; (7) $x \cap x = x$; (8) $x \cup x = x$; (9) $x \cap (y \cap z) = (x \cap y) \cap (x \cap z)$; (10) $x \cup (y \cup z) = (x \cup y) \cup (x \cup z)$; (11) $x \cap (y \cap z) = (y \cap x) \cap (z \cap x)$; (12) $x \cup (y \cup z) = (y \cup x) \cup (z \cup x)$ and the relation (13) $x \cap y = y$ if and only if $y \cup x = x$. Each of the systems I [(1)–(6)], II [(1)–(4), (7), (13)], III [(3)–(6), (9), (10)] is known to be an independent system of axioms for lattices, and the author points out that IV [(5), (6), (11), (12)] is another such system.

The purpose of this report is to determine independence examples for these systems consisting of the least possible number of elements. For instance, the independence of (3)–(6) in I can be shown with algebras consisting of two elements, whereas the independence of (1) and (2) in I can be shown with algebras consisting of five elements. The author shows that these examples are best possible in the following sense: If $(L; \cap, \cup)$ is an algebra consisting of at most four elements in which the axioms (3)–(6) hold, then either both or more of (1) and (2) hold in L. Similar results are obtained for the systems II and III, and the author exhibits independence examples for the system IV, each containing but two elements.

J. Kist (University Park, Pa.)

Birkhoff, Garrett 3398

A new interval topology for dually directed sets.

Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 325–331.

A dually directed set is a partially ordered set in which every pair of elements has an upper bound and a lower bound. Every lattice is dually directed. For such sets the author defines a new interval topology in terms of the order as follows. Let the family C of "closed bounded sets" consist of arbitrary intersections of finite unions of closed intervals $[a, b] = \{x \in D: a \leq x \leq b\}$. Then the closed sets of the dually directed set D in the new interval topology are those sets all of whose intersections with members of the family C are members of C. Any family formed in this way from a family of sets C is called the residual C^* of C. For example, in a k-space the family of all closed sets is the residual of the family of compact sets.

The author shows that for certain important dually directed sets the new interval topology is more useful

and better behaved than the "old" interval topology defined by the reviewer, in which the semi-infinite closed intervals form a sub-basis for the closed sets. For example, the new interval topology of the Euclidean space E^n considered as a direct product of n chains coincides with its usual topology, while the old interval topology does not. He shows also that a closed set in the new topology is bounded if and only if it is a member of the family C, and that a subset of a conditionally complete lattice which is closed in the new topology is compact if and only if it is bounded.

The author states incorrectly (Theorem 1) that the old and new interval topologies coincide if and only if D has universal bounds O and I. Actually the two topologies coincide for all chains, whether they have universal bounds or not. The question of when the two topologies coincide remains open, as does the question of when the new interval topology of a direct product of ordered sets coincides with the cartesian product of the new topologies of the factors. *O. Frink* (University Park, Pa.)

Congruence relations in semi-lattices.

J. London Math. Soc. **39** (1964), 723–729.

Let L be any semi-lattice and let C be the lattice of congruence relations on L. The author shows that C has the following two properties: (i) every element ($\neq 1$) of C is an intersection of dual atoms; (ii) every $s \in C$ has a pseudo-complement $s^* \in C$. L can be embedded in C in the following way. For every $x \in L$ we define $\bar{x} \in C$ by defining $u \equiv v\ (\bar{x})$ to mean $u \vee x = v \vee x$. It is proved that this element $\bar{x}$ is of the form s^*. The author proves that every completely distributive Boolean algebra can be represented as the lattice of congruence relations of a semi-lattice. *E. T. Schmidt* (Budapest)

Avann, S. P. 3402

Increases in the join-excess function in a lattice.

Math. Ann. **154** (1964), 420–426.

In the present paper the author continues his investigations of the join-excess function $\nu[a]$ of a finite lattice L [same Ann. **142** (1960/61), 345–354; MR **23** #A81]; he is mainly concerned with the various ways in which $\nu[a]$ increases in an ascending chain. Several sufficient conditions are given in order that $\nu[a, b] \geq 0$ for $a, b \in L$. Another result is the following. If, in a Jordan-Dedekind lattice L, $\nu[c] = \nu[d]$ for $c \geq d$, then the quotient lattice c/d is lower semi-distributive. *Ph. Dwinger* (Delft)

Jakubík, J.; Kolibiar, M. 3403

Über euklidische Verbände.

Math. Ann. **155** (1964), 334–342.

The authors generalize the notion of euclidean lattice introduced by F. Klein-Barmen [same Ann. **140** (1960), 263–277; MR **22** #6739; J. Reine Angew. Math. **195** (1955), 121–126; MR **18**, 6] to that of α-euclidean lattice, and prove some theorems about the generalization. Let L be a lattice with 0-element, and let α be a cardinal number. An element x of L is said to be primary if the closed interval $[0, x]$ is a chain. L is said to be α-euclidean if it has the following three properties: (1) L contains the join of any set of pairwise disjoint primary elements of cardinal number less than α; (2) every element of L is the join of such a set of pairwise disjoint primary elements; and (3) if z is in L and $z \leq \bigcup x_i$, where the set $\{x_i\}$ has cardinal number less than α, and $z \cap x_i = 0$ for $i \neq k$, then $z \leq x_k$. If α is $\aleph_0$, then α-euclidean reduces to euclidean in the sense of Klein-Barmen.

By the α-product of a family of chains with 0-element is meant the set of all elements x of the direct product of the chains such that the cardinal number of those components of x which are different from 0 is less than α. The authors show that a lattice is α-euclidean if and only if it is an α-product of chains with 0-element. They show also that a lattice S is isomorphic to a dual ideal of an α-product of chains if and only if every principal dual ideal of S is an α-euclidean lattice. Finally, they show that S is isomorphic to an α-product of chains if and only if every principal dual ideal of S and the dual of every principal ideal of S is α-euclidean. *O. Frink* (University Park, Pa.)

Skornjakov, L. A. [Скорняков, Л. А.] 3404

★Complemented modular lattices and regular rings [Дедекиндовы структуры с дополнениями и регулярные кольца].

Gosudarstv. Izdat. Fiz.-Mat. Lit., Moscow, 1961. 198 *pp.* 0.75 *r.*

It has been almost thirty years since von Neumann's early work on complemented modular lattices, continuous geometries, and regular rings. During that period, numerous contributions have been made to these subjects. von Neumann's results have been polished and generalized, and several important new facts about complemented modular lattices have been discovered. The author has done an excellent job of assembling the main theorems of von Neumann and his followers into a short but comprehensive book. The first four sections deal with the representation theorems for complemented modular lattices. The culmination is von Neumann's theorem that every complemented modular lattice with a homogeneous basis of rank four or greater is isomorphic to the lattice of all principal left ideals of a regular ring. The proof of this result is based on ideas introduced by Amemiya [J. Math. Soc. Japan **9** (1957), 263–279; MR **19**, 1154]. Section 5 deals with complete, complemented modular lattices. The results obtained are specialized in Section 6 to continuous

geometries. In particular, the theorem that every continuous geometry admits a unique dimension function is proved. These sections are based on Chapter IV of Maeda's book [*Kontinuierliche Geometrien*, Springer, Berlin, 1958; MR 19, 833]. Section 7 is devoted to uniqueness questions, the main results being those of von Neumann and the author. Section 8 treats *-regular rings, and the application which Kaplansky made of them to prove that every complete, orthocomplemented modular lattice is continuous. It is essentially Kaplansky's proof [Ann. of Math. (2) **61** (1955), 524–541; MR 19, 524] which is given for this theorem, rather than the more direct lattice-theoretic argument of Amemiya and Halperin [Canad. J. Math. **11** (1959), 481–520; MR **22** #1530]. The final section contains a list of 37 interesting problems, along with a discussion of work related to these problems (up to about 1960). It is the reviewer's opinion that the author's book fills very well a definite gap in the mathematical literature. It offers students direct access to some of von Neumann's most beautiful discoveries. The original notes of von Neumann, remarkable as they are, show signs of having been written in the heat of discovery. The only other book on continuous geometries, Maeda's work cited above, is more a monograph than a textbook. The author has taken advantage of numerous advances which have been made in the field of continuous geometries since von Neumann's and Maeda's books were written. The result is a well-organized, lucid book which can serve either as a textbook or a research tool. *R. S. Pierce* (Seattle, Wash.)

Glagolev, V. V. 3405

An estimate of the complexity of the contracted normal form for almost all functions of the logic of algebra. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 770–773.

The author is here concerned with complexities introduced by algorithms for computing minimal disjunctive normal forms (dnf's) of functions of the algebra of logic. Such algorithms begin by searching out reduced dnf's, and choosing those that are minimal from the irreducible dnf's among them. The upper estimate obtained of irreducible dnf's of almost all functions of n variables of algebraic logic is $2^{2^n c_3 \log n \cdot \log \log n}$. A property $Q(f)$ is said to hold for almost all functions of the algebra of logic if $\psi_Q(n)/2^{2^n}$ approaches 1 as n becomes infinite, where $\psi_Q(n)$ is the number of functions of n variables having the property $Q(f)$.

Glagolev, V. V. 3406

A function of a Boolean algebra the number of whose units is equal to the number of monotone functions of n variables. (Russian)

Diskret. Analiz. No. 2 (1964), 10–11.

A Boolean function of 2^n arguments is constructed and shown to be the characteristic function of the set M_n of monotonic Boolean functions of n arguments.

E. J. Cogan (Bronxville, N.Y.)

Dwinger, Ph. 3407

The dual space of the inverse limit of an inverse limit system of Boolean algebras.

Nederl. Akad. Wetensch. Proc. Ser. A **67** = *Indag. Math.* **26** (1964), 164–172.

Consider an inverse limit system of Boolean algebras $\{B_\alpha, f_{\alpha\beta}\}$ with inverse limit B_∞ [see the reviewer's paper, Proc. Amer. Math. Soc. **2** (1951), 566–576; MR **12**, 524]. Let C be an arbitrary Boolean algebra with homomorphic maps g_α into the B_α. Suppose, further, that $f_{\alpha\beta}g_\beta = g_\alpha$ for each pair $\alpha \leq \beta$. Then (Theorem 1) there exists a unique $g \in \mathrm{Hom}(C, B_\infty)$ such that $\pi_\alpha g = g_\alpha$, where π_α is a certain projection of B_∞ into B_α, and dually (Theorem 2). The direct limit X^∞ of the dual spaces can be made (Theorem 5) into a 0-dimensional Hausdorff-space, and the dual space of B_∞ is the largest 0-dimensional Hausdorff compactification of the space obtained from X^∞ by identifying each two points which cannot be separated from each other by open sets. Theorem 6: If the projections π_α of B_∞ into B_α are onto, then the largest 0-dimensional Hausdorff compactification of X^∞ is the dual space X of B_∞, and X^∞ is dense in X (this last correcting an error of the reviewer's) and can be a proper subset of X. {The author has communicated that there are minor misprints on page 165, line 12, and on page 170, line 1, and that, on page 171, the definitions for x_n and x_n^* have been omitted from the proof of Theorem 7.} *F. Haimo* (Belmont, Mass.)

Daigneault, Aubert 3408

Freedom in polyadic algebras and two theorems of Beth and Craig.

Michigan Math. J. **11** (1964), 129–135.

The author proves two theorems in polyadic algebra which are equivalent to the well-known model-theoretic results of Beth [Nederl. Akad. Wetensch. Proc. Ser. A **56** (1953), 330–339; MR **15**, 385] and of Craig [J. Symbolic Logic **22** (1957), 269–285; MR **21** #3318]. By a polyadic algebra is meant a locally finite polyadic algebra of infinite degree. The two theorems are as follows. (1) Let B^* be a family of polyadic algebras, let M^* be a family of monomorphisms of a polyadic algebra M into members of B^*, and let B be the free product of B^* with amalgamation of M^*. Then the intersection of any two factors in B is precisely the amalgamated part. (2) Let V and W be respectively a set of predicates and a set of constants freely generating an equality polyadic algebra A. Let $V = V_1 \cup V_2$ and $V_0 = V_1 \cap V_2$, and for $i = 0, 1, 2$, let A_i be the subalgebra of A generated by V_i and W. Then, whenever $a_1 \leq a_2$ with $a_1 \in A_1$ and $a_2 \in A_2$, there exists $a_0 \in A_0$ such that $a_1 \leq a_0 \leq a_2$. Theorem 1 also has a version for equality polyadic algebras. The proofs are carried out in polyadic algebra, but are in part similar to the proof of Craig's theorem due to A. Robinson [Nederl. Akad. Wetensch. Proc. Ser. A **59** (1956), 47–58; MR **17**, 1178].

Benzaken, Claude 3409

Définition et propriétés de certaines familles de fonctions booléennes croissantes.

C. R. Acad. Sci. Paris **259** (1964), 1369–1371.

This note is an announcement of results which form a continuation of work as yet unpublished. A set of finite Boolean functions forms a family provided it is closed under reduction; the act of obtaining a new function $\bar{f}$ from f by identification of p ($p \leq n$) of its n variables, and composition; replacing one or more variables by other functions. MS is the family of increasing Boolean functions which are non-constant and majorize their respective

duals. $M\Sigma$ is the family generated by $U(x, y, z) = x + yz$. The author considers MS_p $(p \geq 3)$, the set of $f \in MS$ such that each reduction by at least p variables belongs to $M\Sigma$. It turns out that MS_p is a family and $MS_3 = MS \supset MS_4 \supset \cdots \supset M\Sigma$. When $p \geq 4$, a generator for MS_p is found; also the maximal families in MS_p $(p \geq 3)$ are found.

Rosenblatt, David 3410

On the graphs of finite idempotent Boolean relation matrices.

J. Res. Nat. Bur. Standards Sect. B **67B** (1963), 249–256.

This paper presents a graph-theoretic characterization of those binary relations over a finite set which are idempotent under the operation of composition. The set of all binary relations over a finite set of n elements forms a relation algebra under the operations of union, intersection, converse and composition [cf. G. Birkhoff, *Lattice theory*, Amer. Math. Soc., Providence, R.I., 1961; MR **23** #A815]. This algebra may be represented geometrically by the set of all directed graphs with n nodes, and algebraically by the set of all Boolean matrices with n^2 entries. The author proves that a relation is idempotent under composition if and only if its associated graph is a "permanent" graph, in a sense defined at length in the paper. He then derives from this result assorted corollaries for special cases, and discusses applications to ordering and flow problems in large-scale information systems.

{The author calls attention to the fact that line 1, column 1, on page 256 is missing, and should read: "where $\hat{R}$, $\hat{S}$ denote the unions $\bigcup_{n=1}^{\infty} \hat{R}^n$, $\bigcup_{n=1}^{\infty} S^n$. Moreover,".}

Schmidt, E. T. 3411

Universale Algebren mit gegebenen Automorphismengruppen und Kongruenzverbänden.

Acta Math. Acad. Sci. Hungar. **15** (1964), 37–45.

Es wird der folgende Satz bewiesen: Zu einer beliebig vorgegebenen Gruppe G und zu einem beliebig vorgegebenen kompakt erzeugten Verband V existiert eine universale Algebra $\mathbf{A}$, sodass die Automorphismengruppe von $\mathbf{A}$ mit G und der Kongruenzverband von $\mathbf{A}$ mit V isomorph ist. (Ein vollständiger Verband V heisst kompakt erzeugt, wenn sich jedes Element als Vereinigung kompakter Elemente darstellen lässt; dabei heisst das Element $a \in V$ kompakt, wenn stets zu $a \in \bigcup_{\lambda \in \Lambda} x_\lambda$ eine endliche Teilmenge Λ' von Λ existiert mit $a \in \bigcup_{\lambda \in \Lambda'} x_\lambda$.)

Das angegebene Resultat verallgemeinert einen Satz von G. Birkhoff [Rev. Un. Mat. Argentina **11** (1946), 155–157; MR **7**, 411], nach dem zu einer beliebig vorgegebenen Gruppe G eine universale Algebra existiert, deren Automorphismengruppe zu G isomorph ist. Weiterhin liegt mit dem angegebenen Resultat eine Verallgemeinerung eines Satzes von G. Grätzer und E. T. Schmidt [Acta Sci. Math. (Szeged) **24** (1963), 34–59; MR **27** #1391] vor, nach dem zu einem beliebig vorgegebenen kompakt erzeugten Verband V eine universale Algebra existiert, deren Kongruenzverband zu V isomorph ist. (Nach G. Birkhoff und O. Frink [Trans. Amer. Math. Soc. **64** (1948), 299–316; MR **10**, 279] sind die Kongruenzverbände universaler Algebren kompakt erzeugt.)

Der Verfasser konstruiert weiterhin eine einfache universale Algebra zu vorgegebener Automorphismengruppe.

Nöbauer, Wilfried 3412

Transformation von Teilalgebren und Kongruenzrelationen in allgemeinen Algebren.

J. Reine Angew. Math. **214/215** (1964), 412–418.

Let T be an ideal of a polynomial ring $R = r[x_1, \cdots, x_s]$, where r is a commutative ring with unit; further, let $U(x) = (u_1, \cdots, u_s)$ be an s-tuple of polynomials from R; then T^U, the set of all polynomials $f(x_1, \cdots, x_s)$ with $f(u_1, \cdots, u_s) \in T$, is again an ideal of R. The present paper generalizes this type of transformation by defining a generalized distributive and associative law in a universal algebra.

If θ is an n-ary and ψ an r_ν-ary operation in a universal algebra A, θ is distributive in the kth place if

$$\theta(a_1, \cdots, a_{k-1}, \psi(b_1, \cdots, b_r), a_{k+1}, \cdots, a_n) = \psi(\theta(a_1, \cdots, a_{k-1}, b_1, a_{k+1}, \cdots, a_n), \cdots, \theta(a_1, \cdots, b_r, \cdots, a_n)).$$

Now suppose A has r-ary operations ψ_ν and an n-ary operation θ, distributive at the kth place for every ψ_ν. Designate by $(n-1)A$ the set of $(n-1)$-tuples from A. Let T be a subalgebra of $A[\psi_\nu]$ and ρ a congruence relation in it, U a subset of $(n-1)A$. Define T^U by $a \in T^U$ if $\theta(u_1, \cdots, u_{k-1}, a, u_{k+1}, \cdots, u_n) \in T$ for every $(n-1)$-tuple $(u_1, \cdots, u_{k-1}, u_{k+1}, \cdots, u_n)$ in U. Define a relation ρ^U in an analogous manner. Then T^U is a subalgebra of $A[\psi_\nu]$ and ρ^U is a congruence relation in it. Finally, denote by T_U the subalgebra generated by all elements $\theta(u_1, \cdots, a, \cdots, u_n)$ with $a \in T$, the $(n-1)$-tuple in U, and by ρ_U the congruence relation generated by pairs of such θ-operands from $a \equiv b \pmod{\rho}$.

From these general definitions one may prove such theorems as the preservation of all inclusions if $U_1 \subseteq U_2$. One may also consider special cases for A. The author proceeds in both directions, but the bulk of his consideration is given to general formulae rather than to applications.

Rényi, A. 3414
On the distribution of values of additive number-theoretical functions.
Publ. Math. Debrecen **10** (1963), 264–273.
Let $f(n)$ be an additive number-theoretic function. Put

$$f^*(p) = f(p) \quad \text{if} \quad |(fp)| \leq 1,$$
$$f^*(p) = 1 \quad \text{if} \quad |f(p)| > 1.$$

The reviewer proved that if

$$(1) \qquad \sum_p f^*(p)/p \quad \text{and} \quad \sum_p (f^*(p))^2/p$$

both converge, then $f(n)$ has a distribution function [J. London Math. Soc. **13** (1938), 119–127].

The author gives a new analytic proof of this theorem. He uses a method developed by the author and Turán [Acta Arith. 4 (1958), 71–84; MR **20** #3112]. (The reviewer and Wintner proved [Amer. J. Math. **61** (1939), 713–721; MR **1**, 40] that the existence of the distribution function implies the convergence of the two series (1).)

Rotkiewicz, A. 3415
Sur les nombres premiers p et q tels que $pq|2^{pq}-2$.
Rend. Circ. Mat. Palermo (2) **11** (1962), 280–282.
L'auteur démontre trois théorèmes sur les nombres pseudopremiers dont le plus intéressant est le suivant: Pour tout nombre premier p il existe une infinité de nombres composés n, tels que $n\,|\,2^n-2$ et $p\,|\,n$.
A. Schinzel (Columbus, Ohio)

Rotkiewicz, A. 3416
Sur les formules donnant des nombres pseudopremiers.
Colloq. Math. **12** (1964), 69–72.
The positive integer n is pseudoprime if n is composite and n divides 2^n-2. The author presents several formulas which give directly an infinite number of pseudoprimes. Thus, if p is a prime, then $2^{2p-1}/3$ is pseudoprime for $p>3$ and $2^{2p+1}/5$ is pseudoprime for $p>5$. If $F_n = 2^{2^n}+1$, then the integer $M=(2^{F_{n_1}}-1)(2^{F_{n_2}}-1)\cdots(2^{F_{n_k}}-1)$ is pseudoprime if $n_1<n_2<\cdots<n_k$ and $n_k<2^{n_1}$. Using these results, it is shown that each of the progressions $8k+1$, $8k+3$, $8k+5$ and $8k+7$ contains an infinite number of pseudoprimes. The author has proved, in a less elementary fashion, the corresponding theorem for progressions $ak+b$, where $(a,b)=1$ [C. R. Acad. Sci. Paris **257** (1963), 2601–2604; MR **29** #61].
J. B. Kelly (Tempe, Ariz.)

Erdős, P.; Gordon, B.; Rubel, L. A.; Straus, E. G. 3417
Tauberian theorems for sum sets.
Acta Arith. **9** (1964), 177–189.
Let $K=\{k_0,k_1,k_2,\cdots\}$ be any sequence of real numbers, $0<k_0\leq k_1\leq k_2\leq\cdots$. Let, for $x>0$, $S(x)$ be the number of solutions of $\varepsilon_0k_0+\varepsilon_1k_1+\cdots\leq x$, with $\varepsilon_i=0$ or 1 for each i. Put

$$A = \liminf S(x)/x, \qquad B = \limsup S(x)/x,$$
$$\alpha = \liminf 2^n/k_n, \qquad \beta = \limsup 2^n/k_n.$$

The authors show that $A=\alpha$ and $B\geq 2\alpha-\alpha^2/\beta$. Moreover, they show that for any α, β with $0<\alpha<\beta<2\alpha$, it is possible to find a sequence K such that $B=2\alpha^2-\alpha^2/\beta$.

A direct consequence is that if $A=\alpha>0$, then $B=\beta=A=\alpha$; this was previously obtained by Gordon and Rubel [Illinois J. Math. **4** (1960), 367–369; MR **22** #12084]. It is also shown that $A=\alpha=0$ need not imply $B=\beta=0$.

A further theorem states that if $S(x)-x$ is bounded, then $\sum|k_n-2^n|<\infty$; if the k_n are integers, this means that $k_n=2^n$ for all large n. An extension is given to the case that $S(x)-x$ lies between $-f_1(x)$ and $f_2(x)$, where f_1 and f_2 are positive and non-decreasing, and such that $x-f_1(x)$ and $x+f_2(x)$ are increasing.

A final theorem states that $S(x)$ cannot be asymptotically equivalent to $x^a f(x)$, where $0<a<1$, f is continuous, positive, slowly oscillating, and $x^a f(x)$ is strictly increasing.

Sastry, K. P. R. 3418
On the generalised type Möbius functions.
Math. Student **31** (1963), 85–88 (1964).
Let n and k denote rational integers, and let $\prod_{i=1}^r p_i^{a_i}$ denote the standard form of n. The author defines a function $\mu_k(n)$ as follows: $\mu_k(1)=1$, $\mu_k(n)=0$ if n has a kth power divisor, and otherwise $\mu_k(n)=(-1)^{\sum a_i}$. When $k=2$, this function coincides with the Möbius function $\mu(n)$. The author proves six theorems concerning $\mu_k(n)$, all of which are immediate generalizations of theorems valid for $\mu(n)$.
W. Ljunggren (Oslo)

Salmeri, Antonio 3419
Introduzione alla teoria dei coefficienti fattoriali. (English summary)
Giorn. Mat. Battaglini (5) **10** (90) (1962), 44–54.
If n and k are positive integers, and if $n>k$, the factorial coefficient $\begin{bmatrix} n \\ k \end{bmatrix}$ is defined as the sum of all products of k different integers chosen from $1, 2, \cdots, n$. Thus in particular $\begin{bmatrix} n \\ 1 \end{bmatrix}=\frac12 n(n+1)$, $\begin{bmatrix} n \\ n \end{bmatrix}=n!$; also conventionally $\begin{bmatrix} n \\ 0 \end{bmatrix}=1$, $\begin{bmatrix} 0 \\ 0 \end{bmatrix}=1$, $\begin{bmatrix} n \\ k \end{bmatrix}=0$ $(n<k)$. There is some analogy with binomial coefficients. Properties obtained include the following:

$$\prod_{k=1}^n (a+kb) = \sum_{k=0}^n \begin{bmatrix} n \\ k \end{bmatrix} a^{n-k}b^k;$$

$$\sum_{k=0}^n \begin{bmatrix} n \\ k \end{bmatrix} = (n+1)!, \qquad \sum_{k=0}^n (-1)^k \begin{bmatrix} n \\ k \end{bmatrix} = 0;$$

$$\begin{bmatrix} n \\ k \end{bmatrix} = n\begin{bmatrix} n-1 \\ k-1 \end{bmatrix} + \begin{bmatrix} n-1 \\ k \end{bmatrix} = \sum_{s=k}^n s\begin{bmatrix} s-1 \\ k-1 \end{bmatrix}$$
$$= \frac{1}{k}\sum_{s=0}^{k-1} \binom{n+1-s}{k+1-s}\begin{bmatrix} n \\ s \end{bmatrix}.$$

(The last formula is not proved.) $\begin{bmatrix} n \\ k \end{bmatrix}$ is a polynomial in n of degree $2k$, which from examples seems always to contain the factors $(n+1)n(n-1)\cdots(n-k+1)$.

Karst, Edgar 3422

Search limits on divisors of Mersenne Numbers.

Nordisk Tidskr. Informations-Behandling 2 (1962), 224–227.

The author has searched for, and in 227 cases has found, relatively small factors q of Mersenne numbers $2^p - 1$, p a prime > 3000 (mostly p in regions just beyond 3000, 10000, 55000000 and 2^{19}). In this note he gives the upper limit (mostly 10^8) to which the search for q was made, in order to prevent unnecessary work by other researchers.

D. H. Lehmer (Berkeley, Calif.)

Shanks, Daniel 3423

An analytic criterion for the existence of infinitely many primes of the form $\frac{1}{2}(n^2+1)$.

Illinois J. Math. 8 (1964), 377–379.

Let $f(z) = \sum_{n=0}^{\infty} z^{n(n+1)/2}$, and write $g(z) = f^3(z) - 3f(z) = -2 + \{f(z)-1\}^3 - \{f(z)-1\} = \sum_{m=0}^{\infty} a_m z^m$, say. The author points out that, for $m > 0$, $4m+1$ is a prime of the form $\frac{1}{2}(n^2+1)$ if and only if $a_m = (1/m!)g^{(m)}(0) < 0$. Consequently there exist infinitely many primes of the form $\frac{1}{2}(n^2+1)$ if and only if g possesses infinitely many negative coefficients in its Taylor expansion near $z = 0$.

Arithmetical notes. X. A class of totients.

Proc. Amer. Math. Soc. 15 (1964), 534–539.

Part IX appeared in Acta Arith. 7 (1961/62), 417–420 [MR 26 #2406].

A divisor d of a positive integer n is called unitary if $(d, n/d) = 1$. An integer n is called k-free if it has no prime factor of multiplicity $\geq k$ and k-full if it has no prime factor of multiplicity $< k$. The author defines the following functions: $(m, n)_*$ is the largest common divisor of m and n which is a unitary divisor of n; $\alpha_k(n)$ is the maximal k-free unitary divisor n; $\bar{\phi}_k{}^*(n)$ is the number of integers m in a residue system mod n such that $(m, \alpha_k(n))_* = 1$. $\phi^*(n) = \lim_{k\to\infty} \bar{\phi}_k{}^*(n)$; $\mu_k{}^*(n)$ is a multiplicative function such that for p a prime,

$$\mu_k{}^*(p^e) = -1 \quad \text{if} \quad 1 \leq e < k,$$
$$= 0 \quad \text{if} \quad e \geq k;$$

and $\mu^*(n) = \lim_{k\to\infty} \mu_k{}^*(n)$. It will be observed that $\mu_2{}^*$ is the ordinary Möbius function. Also, if $\delta = n/d$, the notation $\sum_{d\cdot\delta=n}$ is used to indicate summation over unitary divisors of n.

The following results, among others, are proved. (1) If $q_k(n)$ denotes the characteristic function of the k-free integers, then $g(n) = \sum_{d\cdot\delta=n} f(d) q_k(\delta)$ if and only if $f(n) = \sum_{d\cdot\delta=n} g(d)\mu_k{}^*(\delta)$; (2) $\bar{\phi}_k{}^*(n) = \sum_{d\cdot\delta=n} d\mu_k{}^*(\delta)$;

$$(3) \qquad \sum_{n\leq x} \bar{\phi}_k{}^*(n) = \tfrac{1}{2}c_k x^2 + O(x \log^2 x)$$

uniformly in k, where

$$c_k = \prod_p \left\{1 - \frac{1}{p^{2k-1}}\left(\frac{p^{2k-2}-1}{p+1}\right)\right\}.$$

Letting $k \to \infty$ in each of the above produces "unitary analogues" of classical theorems, e.g., (1) becomes $g(n) = \sum_{d\cdot\delta=n} f(d)$ if and only if $f(n) = \sum_{d\cdot\delta=n} g(d)\mu^*(\delta)$.

There are some minor misprints.

S. L. Segal (Rochester, N.Y.)

Carlitz, L. 3425

A sequence of integers related to the Bessel functions.

Proc. Amer. Math. Soc. 14 (1963), 1–9.

Let j_i be the zeros of the Bessel function $J_0(z)$. Define a_r for $r \geq 1$ by

$$a_r = 4^r r!(r-1)! \sum_i j_i^{-2r}.$$

Then a_r is an integer.

The author proves some congruence properties of these integers. For example, if p is a prime, $a_{mp} \equiv a_m \pmod{p}$. If $n > p$, then p divides na_n. If $n > 1$, then $n-1$ divides a_n.

Some of the congruence properties are expressed in terms of the coefficients in the power series for $[J_0(z)]^{-2}$.

The numbers a_n are tabulated in factored form for $n = 1(1)18$ and small factors $< 10^4$ are given for $n = 19(1)30$.

Carlitz, Leonard 3426

Some q-identities related to the theta functions.

Boll. Un. Mat. Ital. (3) 17 (1962), 172–178.

Es sei $|q| < 1$. Verfasser setzt $(n)! = (1-q^2)\cdots(1-q^{2n})$, $(0)! = 1$ und $1/(-n)! = 0$ für natürliche Zahlen n. Er beweist die Formel

$$\sum_{s=0}^{\infty} \frac{q^{2s}}{(s)!(n+s)!} \prod_{r=1}^{\infty} (1-q^{2r})^2 = \sum_{r=0}^{\infty} (-1)^r q^{r(r+1+2n)}$$

für alle ganzen n. Zunächst findet er sie unter Benützung einer bekannten Formel, die θ_4 enthält, und einer Reihenentwicklung von $F(x)^{-1}$, wobei

$$F(x) = \prod_1^{\infty} (1-q^{2n-1}x)(1-q^{2n-1}x^{-1})$$

ist. Dann leitet er sie noch unter Benützung einer von F. H. Jackson [Proc. London Math. Soc. (2) 2 (1904/05), 192–220; ibid. (2) 3 (1905), 1–23] eingeführten und von W. Hahn [Math. Nachr. 2 (1949), 340–379; MR 11, 720] diskutierten Funktion her. Schließlich leitet er noch zwei Verallgemeinerungen der obigen Formel her. Bemerkte Druckfehler: In dem Produkt für $F(x)$ sollte n erst bei 1 beginnen. In der Reihe (4) ist das von x unabhängige Glied

nicht 1, sondern lautet so wie der Koeffizient von x^n+x^{-n} für $n=1$. In der ersten Formel unter Punkt 4. fehlt im Nenner ein Index s. *G. Lochs* (Zbl 163, 302)

Carlitz, L. 3427

Generalized Dedekind sums.

Math. Z. **85** (1964), 83–90.

The author derives a reciprocity formula for a generalized Dedekind sum defined by

$$s_p(h,k;x,y) = \sum_{\mu \,(\mathrm{mod}\, k)} \bar{B}_p\left(h\frac{\mu+y}{k}+x\right)\bar{B}_1\left(\frac{\mu+y}{k}\right),$$

where x, y are real, p, h, k are integers, $p \geq 0$, $(h,k)=1$, and $\bar{B}_p$, $\bar{B}_1$ are periodic Bernoulli functions. Special cases have been treated by Rademacher [1963 Number Theory Institute in Boulder, Colorado] and by the reviewer [Duke Math. J. **17** (1950), 147–157; MR **11**, 641]. *T. M. Sur une équation diophantienne considérée par Goormaghtigh.

Ann. Polon. Math. **14** (1963), 69–76.

Let $g_n(x)=1+x+\cdots+x^n$. The author is concerned with integral solutions of equations of the type $g_m(x)=g_n(y)$, where $m>n>1$, $y>x>1$. Goormaghtigh [Intermed. Math. **24** (1917), 88; errata. p. 153] proved that there were exactly two 4-tuples (m,n,x,y) such that $g_m(x)=g_n(y)<10^6$. Kanold [Math. Ann. **132** (1956), 246–255; MR **18**, 718] proved that for fixed x and y there are finitely many m and n such that $g_m(x)=g_n(y)$. Davenport, Lewis and Schinzel [Quart. J. Math. Oxford Ser. (2) **12** (1961), 304–312; MR **25** #1152] proved that for fixed m and n there are finitely many x and y such that $g_m(x)=g_n(y)$, and in case $(n,m)=d>1$ or $m=n+1$, the solutions could be enumerated by use of Runge's method. In this paper the author shows that the only solution of $g_{2n}(x)=g_n(y)$ is $n=2$, $y=5$, $x=2$. The proof is elementary. *D. J. Lewis* (Ann Arbor, Mich.)

A further example of $A^4+B^4+C^4+D^4=E^4$.

Proc. Cambridge Philos. Soc. **60** (1964), 1027–1028.

The example is $A=955$, $B=1770$, $C=2634$, $D=5400$, $E=5491$. The author outlines the search method on an IBM 709 by which this solution was found. See also J. Leech [same Proc. **54** (1958), 554–555; MR **20** #2301]. *O. Taussky-Todd* (Pasadena, Calif.)

Chowla, S. 3430

A remark on a conjecture of C. L. Siegel.

Proc. Nat. Acad. Sci. U.S.A. **51** (1964), 774–775.

The author states that Siegel [Abh. Preuss. Akad. Wiss. Phys.-Math. Kl. **1929**, 1–70] made the conjecture: Let $f(x,y)=0$ be the equation of an algebraic curve of genus $p>0$ over an algebraic number field; then, if the diophantine equation $f(x,y)=0$ has only finitely many (integral) solutions, a bound can be found for the number of solutions which depends only on the number of coefficients of f. The author remarks that this conjecture is false since, for example, he has proved [J. Indian Math. Soc. **20** (1934), 121–128] that, for some $c>0$ and infinitely many n, the equation $x^2+y^3=n$ has at least $c\log\log n$ solutions in positive integers. *E. S. Barnes* (Adelaide)

Froda, Alexandre 3431

Sur l'irrationalité du nombre 2^e.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 472–478.

Put

$$\varepsilon_r = \sum_{s=1}^{r}\frac{1}{s!},\quad x_r=1,\quad y_r=2^{\varepsilon_r},\quad q_r=\frac{2^{\varepsilon_r}}{r},\quad p_r=\frac{q_{r+1}}{q_r},$$

$$\alpha_r=\frac{y_r}{x_r},\quad \alpha=\lim \alpha_r = 2^{e-1},\quad \xi_r = 1-\left[\frac{x_r}{q_r}\right]+\frac{x_r}{q_r},$$

$$\eta_r=\frac{y_r}{q_r}-\left[\frac{y_r}{q_r}\right].$$

Further, assume that $\alpha=u/v$, where $u\geq 1$, $v\geq 1$, $(u,v)=1$, is rational. The following four properties are shown to hold.

$$\frac{y_{r+1}}{q_{r+1}}-\frac{y_r}{q_r}\geq\frac{y_{r+2}}{q_{r+2}}-\frac{y_{r+1}}{q_{r+1}};$$

$$0<\frac{x_{r+1}}{q_{r+1}}-\frac{x_r}{q_r}<\frac{x_{r+2}}{q_{r+2}}-\frac{x_{r+1}}{q_{r+1}}\quad\text{for sufficiently large } r;$$

$\eta_r=0$ for all r; $\xi_{r_s}\geq\xi_{r_{s+1}}$ for an infinite sequence of suffixes r_s. In a previous paper [Math. Scand. **12** (1963), 199–208; MR **29** #2222] it was shown that these properties imply the irrationality of α, hence of 2^e, if the sequence $\{\alpha_r\}$ consists of rational elements. This is not so in the present case, but, according to the author, this condition is superfluous. *K. Mahler* (Canberra)

Davenport, H. 3432

A note on Diophantine approximation. II.

Mathematika **11** (1964), 50–58.

Let $\|\alpha\|$ denote the distance from the real number α to the nearest integer. Cassels [Mathematika **3** (1956), 109–110; MR **18**, 875] proved the following. Let $\lambda_1,\cdots,\lambda_r$ be given real numbers, then there exists a real number α such that all numbers $\alpha+\lambda_1,\cdots,\alpha+\lambda_r$ are "badly approximable"; more precisely, they satisfy $\|(\alpha+\lambda_q)u\|>C/u$ $(q=1,\cdots,r)$ for all positive integers u, where $C=C(r)>0$, i.e., the partial quotients of their continued fractions are bounded.

In the paper reviewed here this result is generalized in different directions. One of the simplest is the following: "Suppose $f_1(\alpha),\cdots,f_r(\alpha)$ are functions of a real variable α such that their first derivatives are continuous in some interval containing α_0, and suppose that none of these derivatives is zero for $\alpha=\alpha_0$. Then there exists α such that $\|f_q(\alpha)u\|>C/u$ $(q=1,\cdots,r)$ for all positive integers u, where $C=C(f_1,\cdots,f_r)>0$. The set of those α has the cardinal of the continuum".

This theorem can be extended to simultaneous Diophantine approximation of k-tuples of real numbers. In the two-dimensional case this result reads: "Let $f_1(\alpha,\beta),\cdots,f_r(\alpha,\beta)$ and $g_1(\alpha,\beta),\cdots,g_r(\alpha,\beta)$ be real functions with continuous partial derivatives of the first order in a neighbourhood of some point (α_0,β_0). Suppose that the Jacobian of each pair (f_q,g_q) does not vanish for (α_0,β_0)

($q=1, \cdots, r$). Then there exists a set of pairs (α, β) with the cardinal of the continuum, for which

$$\max(\|f_q(\alpha, \beta)u\|^2, \|g_q(\alpha, \beta)u\|^2) > C/u$$

for all integers $u>0$ and for $q=1, \cdots, r$, where

$$C = C(f_1, \cdots, f_r, g_1, \cdots, g_r) > 0".$$

Finally, the author shows that one can go even further and find values of functions which possess properties of being badly approximable of different dimensions at the same time. The exact wording of these results is omitted in this review.

The author uses a geometrical method of proof already used by himself in a special case in Part I [*Studies in mathematical analysis and related topics*, pp. 77–81, Stanford Univ. Press, Stanford, Calif., 1962; MR 26 #3671].

Relations between the digits of numbers and equal sums of like powers.

Canad. J. Math. **16** (1964), 626–636.

The author derives a general identity involving the digits of integers in an arbitrary system of notation and deduces a few solutions of the Tarry-Escott problem [Lehmer, Scripta Math. **13** (1947), 37–41; MR **9**, 78]. For instance, we have Theorem 4: The integers from 0 to db^m-1, inclusive, whose base d expansions do not have a units digit equal to any one of a fixed, but arbitrary, set of $d-b$ of the integers $0, 1, \cdots, d-1$, may be split into b classes such that the sum of the tth powers of the elements in a given class is the same for all classes for all t from 0 to $m-1$, inclusive, and the splitting may be accomplished in $(b-1)!^{m-1}$ ways. Theorem 7: For each t, $0\leq t<m$, the sum of the tth powers of the integers from 0 to 3^m-1, inclusive, having no 1's and an odd number of 2's in their base 3 expansions equals the sum of the tth powers of those integers in the same range having no 1's and an even number of 2's. A numerical example for $m=3$ is

$$0^t+8^t+20^t+24^t = 2^t+6^t+18^t+26^t, \qquad t=0, 1, 2.$$

Callahan, Francis P. 3436

Density and uniform density.

Proc. Amer. Math. Soc. **15** (1964), 841–843.

An elementary proof is given that the multiples modulo 1 of any irrational number θ are uniformly dense in the unit interval. Whereas the standard elementary proof uses rational approximations of θ, the device here is to prove that any subinterval I of length $1/k$ gets a proportional share of the multiples of θ in the limiting sense, k being any positive integer. This is done by choosing an integer t so that $t\theta$ is close to $1/k$ (mod 1) and then observing that I and its translates $I+rt\theta$ taken modulo 1 with $1\leq r\leq k-1$ approximately cover the unit interval. The proof generalizes to the n-dimensional case of uniform density, if density in the n-cube is assumed.

On the fractional parts of θx^2 and ϕx^2.

J. London Math. Soc. **34** (1959), 353–357.

Nach Heilbronn [Quart. J. Math. Oxford Ser. **19** (1948), 249–256; MR **10**, 284] gibt es zu jedem $\varepsilon>0$ ein $C(\varepsilon)$, so daß für jedes reelle θ und jedes $N\geq 1$ eine ganze Zahl x existiert, für die $1\leq x\leq N$, $\|\theta x^2\|<CN^{-1/2+\varepsilon}$ gilt. Für die simultane Approximation zweier beliebiger reeller Zahlen θ, ϕ gilt: Zu jedem $\varepsilon>0$ gibt es ein $C(\varepsilon)$ und ein ganzes x, so daß $1\leq x\leq N$, $\|\theta x^2\|<CN^{-1/8+\varepsilon}$, $\|\phi x^2\|<CN^{-1/8+\varepsilon}$ gilt, wobei wieder $N\geq 1$ gegeben ist. Der Beweis erfolgt mit Hilfe von trigonometrischen Summen. Man vergleiche die neue Arbeit des Verfassers [Mathematika **5** (1958), 30–37; MR **20** #3103], in der eine Verallgemeinerung auf beliebige quadratische Formen durchgeführt wurde.

N. Hofreiter (Zbl 88, 257)

Pall, G. 3439

Simultaneous representation by adjoint quadratic forms.

Acta Arith. **9** (1964), 271–284.

Let φ be an n-ary quadratic form with real coefficients and φ' its adjoint form, with matrices $A=(a_{ij})$ and $A'=(a_{ij}')$, respectively. Two real numbers m and m' are said to be simultaneously represented by φ and φ' if there exist integers x_i, z_i' ($i=1, 2, \cdots, n$) such that

$$m = \sum a_{ij}x_ix_j, \qquad m' = \sum a_{ij}'z_i'z_j', \qquad 0 = \sum x_iz_i',$$

where the sums are over all i and j. The pair of column

vectors $x=(x_i)$ and $z'=(z_i')$ is called a simultaneous representation, and the representation is primitive if each vector is.

An algorithm is given which produces all the simultaneous representations of given m and m' by φ and φ', each set of primitive representations (a set being an aggregate Wx, and $W'z'$, W running over the unimodular automorphs of φ) being associated with a unique class of quadratic forms in $n-2$ variables and a certain set of solutions of certain quadratic congruences modulo m and m'. In particular there is Theorem 6. Every set of simultaneous and primitive representations of nonzero numbers m and m' by the real nonsingular n-ary quadratic form φ and its adjoint φ' is associated with a unique class of matrices G of order $n-2$ and, if we select a particular matrix G in this class, with a unique G-set. One such set of representations obtains for every matrix G and accompanying G-set for which a certain matrix B is equivalent to the matrix of φ. *Burton W. Jones* (San Jose)

Watson, G. L. 3440

A problem of Dade on quadratic forms.

Mathematika **10** (1963), 101–106.

Let $f(x_1, \cdots, x_n)$, $n \geq 3$, be a non-singular quadratic form with rational integer coefficients whose greatest common divisor is 1. The problem is that of finding an algebraic extension E of $\mathbf{Q}$ such that the equation $f(x_1, \cdots, x_n)=1$ has a solution in integers $x_1, \cdots, x_n$ of E. Using theorems from the theory of integral quadratic forms, the author proves the following theorems, which give constructions for E as quadratic extensions of $\mathbf{Q}$. Theorem 1: Suppose $n \geq 4$, then there exists a rational integer q such that $f(y_1+z_1\sqrt{q}, \cdots, y_n+z_n\sqrt{q})=1$ has a solution in rational integers y_i, z_i $(1 \leq i \leq n)$. Theorem 2: Suppose that $n=3$, then there exist rational integers q, r such that the equation $f(y_1+z_1\sqrt{q}+w_1\sqrt{r}, \cdots, y_3+z_3\sqrt{q}+w_3\sqrt{r})=1$ has a solution in rational integers y_i, z_i, w_i $(1 \leq i \leq 3)$.

Dade, E. C. 3441a

Algebraic integral representations by arbitrary forms.

Mathematika **10** (1963), 96–100.

Dade, E. C. 3441b

A correction.

Mathematika **11** (1964), 89–90.

Let $\mathfrak{O}$ be the integral closure of the rational integers in some algebraic closure K of the rationals, and let $f(X_1, \cdots, X_n)$ be a polynomial with relatively prime coefficients in $\mathfrak{O}$. The first of these papers generalizes the result of Watson [see #3440 above] as follows: For some $x_1, \cdots, x_n \in \mathfrak{O}$, $f(x_1, \cdots, x_n)$ is a unit. An immediate deduction from this is that if $f(X_1, \cdots, X_n)$ is homogeneous, then $f(x_1, \cdots, x_n)=1$ for suitable $x_1, \cdots, x_n \in \mathfrak{O}$.

The proof depends on a theorem of Steinitz, which in turn requires that a certain determinant shall be divisible by ideals $\mathfrak{q}_1, \cdots, \mathfrak{q}_s$ of $\mathfrak{O}$. Siegel has pointed out that the proof of this last is incomplete at one point, and the author supplies a correct version in the second of these papers.

It should be noted that, whereas Watson's result [#3440] essentially gives the extension in which $x_1, \cdots, x_n$ lie in terms of the coefficients of the form, the present generalization is just an existence theorem.

Ehrhart, Eugène 3442

Calcul de la mesure d'un polyèdre entier par un décompte de points.

C. R. Acad. Sci. Paris **258** (1964), 5131–5133.

In Euclidean k-space, let G_1 denote the lattice of points with integral coordinates, let $G_n=G_1/n$ and let Π be any polyhedron whose vertices are points of G_1. The volume and surface area (les mesures réticulaires) of Π are expressed in terms of the numbers of points in the sets $G_n \cap \Pi$ $(n=1, 2, \cdots, [\frac{1}{2}(k+1)])$.

J. H. H. Chalk (Toronto, Ont.)

Von Wolff, M. R. 3443

Application of the domain of action method to $|xy| \leq 1$.

Illinois J. Math. **8** (1964), 500–522.

Let $\mathscr{S}$ be a star domain in the affine plane, symmetric about O. A set of points $\mathscr{P}$ is said to provide a packing for $\mathscr{S}$ if the domains $\{\mathscr{S}+P\}$, where $P \in \mathscr{P}$, have the property that no domain $(\mathscr{S}+P_0)$ contains the center of another in its interior; such a point set $\mathscr{P}$ is called an admissible point set for $\mathscr{S}$. Let $A(t)$ denote the number of points of $\mathscr{P}$ in the square $|x|<t$, $|y|<t$. Then the density $\mathscr{D}(\mathscr{P})$ of $\mathscr{P}$ is defined as $\limsup_{t\to\infty} A(t)/4t^2$. A norm distance $N(X)=N(OX)$ is a real-valued function which is non-negative, continuous and homogeneous. A convex distance function or Minkowski distance, where M is a norm distance with the additional properties that $M(PQ)=0$ implies $P=Q$, $M(PQ) \leq M(PR)+M(RQ)$.

Let $\mathscr{P}$ be a point set in the plane, and let M be a Minkowski distance. The domain of action $D(P)=D(P, M, \mathscr{P})$ of a point P relative to M and $\mathscr{P}$ is the set of all points X in the plane for which $M(PX) \leq M(QX)$, $Q \in \mathscr{P}$, $Q \neq P$.

Consider the domain $\mathscr{S}: |xy| \leq 1$. Let

$$M(P_1, P_2) = \tfrac{1}{2}(|x_2-x_1|+|y_2-y_1|).$$

N. E. Smith [Ph.D. Dissertation, McGill Univ., Montreal, Que., 1951] proved that a critical lattice gives the closest packing of $\mathscr{S}: |xy| \leq 1$; in other words, if $\mathscr{P}$ is any $\mathscr{S}$-admissible point set, $\mathscr{D}(\mathscr{P}) \leq 1/\sqrt{5}$. M. Rahman [Ph.D. Dissertation, McGill Univ., Montreal, Que., 1957] indicated that one might get as sharp a result by using domain of action method; this is indeed the case as the author proves that if O is any point of an admissible point set for the region $\mathscr{S}: |xy| \leq 1$, then $|D(O)| \geq \sqrt{5}$.

M. S. Cheema (Tucson, Ariz.)

Chalk, J. H. H. 3444

A local criterion for the covering of space by convex bodies.

Acta Arith. **9** (1964), 237–243.

Let K be a convex body in n-dimensional Euclidean space R^n, and Λ_0 the integer lattice. Let $\mu=\inf\{t: tK+\Lambda_0=R^n\}$ be the non-homogeneous minimum, and let $\lambda_K{}^*$ be the smallest value of t such that for some $d \in R^n$ the convex

body $tK+d$ contains "a K-dimensional set of $K+1$ points of Λ_0". The following inequality is proved:

$$\mu \leq \tfrac{1}{2}(n+1)\lambda_n^* \qquad \text{if } n \text{ is odd,}$$

$$\leq \tfrac{1}{2}n\left(1+\frac{1}{n+1}\right)\lambda_n^* \quad \text{if } n \text{ is even.}$$

The value of μ is calculated for the modified octahedron.

Keller, H. B.; Swenson, J. R. 3445

Experiments on the lattice problem of Gauss.

Math. Comp. **17** (1963), 223–230.

Where $A(r)$ is the number of lattice points, i.e., points with integer coordinates, in the circle $x^2+y^2 \leq r^2$, it has been shown by Hua that

$$(1) \qquad E(r) = A(r) - \prod r^2 = O(r^\theta)$$

holds for $\theta = 13/20$ and by Hardy that it does not hold for $\theta = \frac{1}{2}$. It has been conjectured that (1) holds for $\theta > \frac{1}{2}$.

The authors describe a method of calculating $E(r)$ and tabulate sample values of it for r up to 250,002. For some values of $r > 10^5$ there are values of $\ln |E(r)|/\ln r$ greater than Hua's upper bound of 0.65, while for all calculations performed, it was found that $|E(r)|/r^{1/2} < 7$. Thus it appears that the range of values of r considered, though large, is still not large enough to support any conjecture [cf. the reviewer and Gotlieb, Math. Comp. **16** (1962), 282–290; MR **27** #5722].

Maak, Wilhelm 3446

Gitterpunktsummen.

Nachr. Akad. Wiss. Göttingen Math.-Phys. Kl. II **1964**, 59–66.

Bekanntlich ist $\Gamma(2)$ (die Gruppe der ganzzahligen Matrizen $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ mit $a \equiv d \equiv 1$ (4), $b \equiv c \equiv 0$ (2)) eine freie Gruppe von zwei Erzeugenden $A = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix}$ und $B = \begin{pmatrix} 1 & 0 \\ -2 & 1 \end{pmatrix}$. Die Anzahl der Faktoren A bzw. B, aus denen ein Element $L = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma(2)$ aufgebaut ist, ist eine Funktion der ganzrationalen Zahlen a, b, c, d. Es wird eine Methode angegeben, die es gestattet, diese Anzahle durch Abzählen von Gitterpunkten, also ohne eigentliche Rechnung zu bestimmen. Ganz ähnlich Abzählungen können dazu dienen, die Werte der Rademacherschen Φ-Funktion [Rademacher, J. Reine Angew. Math. **167** (1932), 312–336] und damit die der Dedekindsummen zu bestimmen. Es wird die Transformationstheorie der Weierstraßschen σ-Funktion benutzt. Für die angegebenen und weitere Sätze wird demnächst Herr Burde elementare Beweise an anderer Stelle veröffentlichen. Die angegebenen Methoden führen zu einer Fülle weiterer Sätze, die mehr oder weniger interessant erscheinen, je nach der Einstellung, die man gegenüber den Fragestellungen einnimmt, die sie berühren.

Gyires, B. 3447

On a generalization of Wilson's theorem.

Acta Arith. **6** (1960), 185–191.

$A_0, A_1, \cdots, A_{r-1}$ seien $(n \times n)$-Matrizen aus ganzen rationalen Zahlen, E die zugehörige Einheitsmatrix. Ersetzt man die Elemente 1 der Einheitsmatrix r-ter Ordnung der Reihe nach durch $A_0, A_1, \cdots, A_{r-1}$ und besetzt man alle übrigen Felder durch Nullen, so entsteht eine Matrix der Ordnung nr, die mit $\langle A_0, A_1, \cdots, A_{r-1}\rangle$ bezeichnet sei. Ferner seien die Koeffizienten von $f(z) = \sum a_{\rho-1}z^{\rho-1} + z^r$ $(\rho = 1, 2, \cdots, r)$ ganz rational, die Wurzeln α_ρ von $f(z) = 0$ paarweise verschieden und die Lösungen β_ρ von $f(z) \equiv 0$ (mod p), wo p Primzahl ist, paarweise inkongruent; außerdem $M(z) = \sum A_{\rho-1}z^{\rho-1}$, $\mathfrak{A} = \langle M(\alpha_1), \cdots, M(\alpha_r)\rangle$, $\mathfrak{B} = \langle M(\beta_1), \cdots, M(\beta_r)\rangle$. Schließlich seien $\mathfrak{V}$ und $\mathfrak{W}$ die Matrizen, die aus den Vandermondeschen Matrizen r-ter Ordnung $(\alpha_{ij}) = (\alpha_j^{i-1})$ bzw. $(\beta_{ij}) = (\beta_j^{i-1})$ entstehen, wenn man jedes Element durch sein Produkt mit E ersetzt. Dann gilt, wie Verfasser zeigt, I. $\mathfrak{V}\mathfrak{A}\mathfrak{V}^{-1} \equiv \mathfrak{W}\mathfrak{B}\mathfrak{W}^{-1}$ (mod p), woraus durch Übergang zu den Determinanten II. $|M(\alpha_1)| \cdots |M(\alpha_r)| \equiv |M(\beta_1)| \cdots |M(\beta_r)|$ folgt. Durch Spezialisierung ergibt sich aus II. unter anderem: $M(1) \cdots M(p-1) \equiv M(\omega_1) \cdots M(\omega_{p-1})$, wo $\omega_1, \cdots, \omega_{p-1}$ die $(p-1)$-ten Einheitswurzeln sind. Diese Kongruenz zu beweisen, war vom Verfasser schon früher als Aufgabe gestellt worden. Mit $M(z) = 1$ folgt aus ihr der Wilsonsche Satz. Der Beweis von I. wird mit Hilfe einer leichten Verallgemeinerung eines Satzes von J. Wellstein [Jber. Deutsch. Math.-Verein. **42** (1932), Abt. 2, 7–9] geführt. Zum Schluß liefert Verfasser noch einen direkten Beweis für ein Nebenresultat von L. Rédei und P. Turán [Acta Arith. **5** (1959), 223–225; MR **21** #4148], das er so formuliert: Notwendig und hinreichend dafür, daß eine zyklische Matrix $(p-1)$-ter Ordnung mod p den Rang k hat, ist $s_{p-1} \equiv \cdots \equiv s_{k+1} \equiv 0$ (mod p); $s_k \not\equiv 0$, wobei s_i die Summe der Hauptminoren i-ter Ordnung ist.

On a class of finite homomorphisms. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 33–36.

Let $h(n)$, $n = 1, 2, \cdots$, be a generalized principal character, i.e., a completely multiplicative function of n, not identically zero, taking only a finite number of (complex) values and satisfying $\sum_{n \leq x} h(n) = ax + O(1)$, $a \neq 0$. The author shows in a basically elementary way that every such character is a Dirichlet character.

S. Knapowski (Marburg)

Katai, I. [Kátai, I.] 3450

An asymptotic formula in the theory of numbers. (Russian)

Ann. Univ. Sci. Budapest. Eötvös Sect. Math. **6** (1963), 83–87.

The following conditional result is proved. If for all σ_0,

$\frac{1}{2} \leq \sigma_0 \leq 1$, $T > 2$, the number of zeros of Riemann's zeta-function $\zeta(\sigma+it)$ in the rectangle $\sigma_0 \leq \sigma \leq 1$, $|t| \leq T$, is equal to $O(T^{2(1-\sigma_0)} \log^2 T)$, then

$$\sum_{n \leq u} \left(\sum_{p<n} \frac{1}{n-p} \right)^2 = u + o(u),$$

where the inner sum is taken over all primes $p < n$.

J. Kubilius (Vilnius)

Kátai, I. 3451

On certain sets of integers.

Ann. Univ. Sci. Budapest. Eötvös Sect. Math. **6** (1963), 43–48.

Let $c_1, \cdots, c_{n+1}$ $(n \geq 2)$ be integers different from zero. A sequence of positive integers $u_1, u_2, \cdots$ is called an A-set if the equality $c_1 u_{i_1} + \cdots + c_n u_{i_n} = c_{n+1} u_{i_{n+1}}$ implies $i_1 = \cdots = i_n = i_{n+1}$. Denote by $A(x)$ the largest number of integers which can be selected from 1, 2, $\cdots$, $[x]$ to form an A-set, $a(x) = A(x)/x$. Let m be a positive integer which does not divide the numbers c_i $(i = 1, \cdots, n+1)$. A set $a_1, \cdots, a_k$ of incongruent residues modulo m will be called a $\mathscr{D}$-set if the congruence $c_1 a_{i_1} + c_n a_{i_n} \equiv c_{n+1} a_{i_{n+1}} \bmod m$ implies $i_1 = \cdots = i_n = i_{n+1}$. Denote by $\mathscr{D}(m)$ the largest number of residues modulo m to form a $\mathscr{D}$-set, $d(m) = \mathscr{D}(m)/m$.

The author obtains the following theorems. (1) If $c_1 + \cdots + c_n \neq c_{n+1}$, then $\lim \inf_{x\to\infty} a(x) > 0$, $\lim \inf_{m\to\infty} d(m) > 0$. (2) If $c_1 + \cdots + c_n = c_{n+1}$, then $\lim_{x\to\infty} a(x) = 0$. (3) If $c_1 + \cdots + c_n = c_{n+1}$, $c_l \not\equiv 0 \bmod m$ $(l = 1, \cdots, n+1)$, then $\lim_{m\to\infty} d(m) = 0$.

The assertion (2) in the case $n = 2$, $c_1 = c_2 = 1$ was conjectured by P. Turán and P. Erdős and solved by K. F. Roth [J. London Math. Soc. **28** (1953), 104–109; MR **14**, 536].

J. Kubilius (Vilnius)

Rémond, Paul 3452

Évaluations asymptotiques dans certains semi-groupes.

C. R. Acad. Sci. Paris **258** (1964), 4179–4181.

Let $\mathscr{E}(E^*)$ be a commutative semigroup having a subset of primes E^* such that if $A \in \mathscr{E}$, then A has a unique expression in the form

$$A = P_1^{\alpha_1} \cdots P_n^{\alpha_n} \qquad (P_i \in E^*, \alpha_i \in Z).$$

Assume that there is a norm N from $\mathscr{E}$ to the natural numbers with $N(A) \geq 2$ and $N(e) = 1$. The purpose of this note is to extend certain results of H. Delange [Ann. Sci. École Norm. Sup. (3) 78 (1961), 1–29]. A normed semigroup $\mathscr{E}(E^*)$ is called a D semigroup if

$$\sum_{A \in \mathscr{E}} N(A)^{-s} = u(s)(s-1)^{-\mu},$$

$s = \sigma + it$, $\sigma > 1$, $\mu > 0$, $u(s)$ holomorphic for $\sigma \geq 1$, $u(s) \neq 0$ for $\sigma \geq 1$. The set E^* is said to be regular if, for $\sigma > 1$,

$$\sum_{P \in E^*} N(P)^{-s} = -\mu \log(s-1) + r(s),$$

$\mu \geq 0$ and $r(s)$ holomorphic for $\sigma \geq 1$. μ is called the density of E^*. A normed semigroup $\mathscr{E}$ is a D semigroup if and only if the set E^* of primes is regular with density $\mu > 0$. In addition, the author announces certain asymptotic relations for D semigroups and deduces the following corollary. If $k = 2, 4, p^a, 2p^a$, where p is a rational prime > 2,

$$\sum_{\substack{n \leq x \\ n \equiv 1 \pmod k}} 1 \sim \left(\frac{\phi(\phi(k))}{[\phi(k)]^{\phi(k)}[\phi(k)-1]!} \right) \left(\frac{x(\log\log x)^{\phi(k)-1}}{\log x} \right),$$

where the summation extends over those n which are not the product of two integers congruent to 1 mod k.

R. Ayoub (University Park, Pa.)

Wright, E. M. 3453

Partition of multipartite numbers into k parts.

J. Reine Angew. Math. **216** (1964), 101–112.

Let $q(k; n_1, \cdots, n_j)$ be the number of partitions of the vector $(n_1, \cdots, n_j)$ into k parts $(x_1, \cdots, x_j)$, where the x_i are non-negative integers. The author estimates q for large $n_1, \cdots, n_j$. The problem is first reduced to studying the coefficients c_n of $J(x) = \sum_{n=0}^\infty c_n x^n = \prod_{i=1}^p (1-x^{a_i})^{-1}$, where $a_1 + \cdots + a_p$ is a partition of k. If $u \geq 1$, let $s(u)$ be the number of $a_i \equiv 0 \pmod u$. By partial fractions one gets $J(x) = \sum_{s(u)>0} J_u(x)$, where the poles of $J_u(x)$ are at the primitive uth roots of unity. If $J_u(x) = \sum_{n=0}^\infty C(u, n) x^n$, then $C(u, n)$ is of the form $\sum_{l=0}^{s(u)-1} \varepsilon_l(u, n) n^l$, where $\varepsilon_l(u, n+u) = \varepsilon_l(u, n)$. Using this to define $C(u, n)$ for $n < 0$, one gets $C(u, n) = (-1)^{p-1} C(u, -n-k)$. Putting $N = n + \frac{1}{2}k$, this leads for $u = 1$ and 2 to an expansion $C(u, n) = \sum_{0 \leq 2\nu \leq s(u)-1} \chi_u(\nu) N^{s(u)-1-2\nu}$, where $\chi_1(\nu)$ and $(-1)^n \chi_2(\nu)$ are independent of n. Explicit formulas are obtained for χ_1 and χ_2 in terms of Bernoulli numbers. Then $q(k; n_1, \cdots, n_j)$ is expanded in powers of $N_i = n_i + \frac{1}{2}k$, and these formulas are used to evaluate the leading terms. For $k \leq 4$ this gives explicit formulas for q.

On Gaussian sums.

Proc. Nat. Acad. Sci. U.S.A. **48** (1962), 1127–1128.

The author proves the following theorem. Let

$$\sum_{n=1}^{p-1} \chi(n) e^{2\pi i n/p} = s(z)\sqrt{p};$$

then $s(z)$ is a root of unity only for the case of a quadratic character $\chi^2 = \chi_0$.

A. Vinogradov (RŽMat 1963 #3 A98)

Wiesing, Eduard 3457

Elementare Beweise des Primzahlsatzes mit Restglied. II.

J. Reine Angew. Math. **214/215** (1964), 1–18.

The author continues his researches concerning the elementary proof of the prime number theorem; the formula

$$(1)\qquad \psi(x) = x + O(x/\log^{\alpha} x)$$

is now proved for every α as announced in a previous paper [same J. **211** (1962), 205–214; MR **27** #119]. The author also sketches the proof of the corresponding result concerning primes in an arithmetical progression.

The main tool in the proof is an analogue of the celebrated Selberg formula. If we set

$$(2)\qquad \rho(x) = \sum_{n \leq \exp x} \left(\frac{1}{n} - \frac{\Lambda(n)}{n}\right) - 2C,$$

the fundamental result in the paper is the proof that

$$(3)\qquad \rho(x) = O(x^{-\alpha}) \quad \text{for every } \alpha,$$

from which (1) can be easily deduced.

The author follows in the proof a cyclic method. From (3) he deduces the relations:

$$(4)\qquad \begin{aligned} \rho(x) &= \frac{1}{x}\int_{0-}^{x} \rho(x-y)\,d\rho(y) + O(x^{-\beta}),\\ |\rho(x)-\rho(y)| &\leq |x-y| + O(x^{-\beta}) \end{aligned}$$

for $\beta < \alpha + 1$, and from (4) he can also deduce (3) with β instead of α. The deduction of (3) from (4) is given only for a certain $\alpha' > \beta - 1$. The proof for $\alpha = \beta$ is only briefly sketched.

The proof of (1) for every α, as is pointed out by the author, was obtained at the same time by E. Bombieri following a different method founded on an important extension of the Selberg formula [Riv. Mat. Univ. Parma (2) **3** (1962), 393–440; MR **27** #4804]. *M. Cugiani* (Milan)

Cohen, Eckford 3458

Some asymptotic formulas in the theory of numbers.

Trans. Amer. Math. Soc. **112** (1964), 214–227.

Denote by $Q^2(n)$ the largest square divisor of n. Let α be an arbitrary non-negative real number and S any non-empty set of positive integers. Then for $x \to \infty$,

$$\sum_{\substack{n \leq x\\ Q(n) \in S}} \left(\frac{n}{Q^2(n)}\right)^{\alpha} = \frac{6x^{\alpha+1}}{\pi^2(\alpha+1)} \sum_{\substack{n=1\\ n \in S}}^{\infty} n^{-2\alpha-2} + O(x^{\alpha+1/2}R_{\alpha}(x,S))$$

uniformly in S, where

$$R_{\alpha}(x,S) = \sum_{\substack{n \leq \sqrt{x}\\ n \in S}} n^{-2\alpha-1},$$

if this sum is non-empty; otherwise, $R_{\alpha}(x,S) = 1$.

The author proves two more asymptotic formulas: (1) for an analogous sum with the additional condition $(n, Q^2(n)) = 1$, and (2) for an analogous sum with summands $(n/Q^*(n))^{\alpha}$, where $Q^*(n)$ is the largest divisor of n with no simple prime factors.

He deduces from these results 42 corollaries, which yield estimates due to Cesàro [Ann. Mat. Pura Appl. (2) **13** (1885), 251–268], Feller and Tornier [Math. Ann. **107** (1932), 188–232], Kanold [J. Reine Angew. Math. **193** (1954), 250–252; MR **16**, 569], Rényi [Acad. Serbe Sci. Publ. Inst. Math. **8** (1955), 157–162; MR **17**, 944] and the author [Duke Math. J. **28** (1961), 183–192; MR **25** #3916]. *J. Kubilius* (Vilnius)

Linnik, Ju. V.; Skubenko, B. F. 3459

Asymptotic distribution of integral matrices of third order. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **19** (1964), no. 3, 25–36.

The authors give an asymptotic formula for the number of integral matrices $X = (x_{ij})$ of third order with determinant $\det(X) = N$, $N \to \infty$, where the X's are subjected to the following additional restrictions: (1) $X \equiv A \pmod p$ ($p \nmid N$ a given prime, A a given integral matrix of third order with determinant $N \pmod p$); (2) $\bar{X} = (N^{-1/3}x_{ij})$ belongs to a prescribed sufficiently regular domain Ω.

S. Knapowski (Marburg)

Dade, E. C.; Taussky, O. 3460

On the different in orders in an algebraic number field and special units connected with it.

Acta Arith. **9** (1964), 47–51.

Let $\mathfrak{C} = \mathbf{Z}[\theta]$, $\mathfrak{C}' = \mathbf{Z}[\lambda]$ be two principal orders in an algebraic number field F of degree n over the rationals $\mathbf{Q}$, $\mathfrak{C}' \subset \mathfrak{C}$. Each element of the ring $\mathfrak{C}[\bar{X}_0, \cdots, \bar{X}_{n-1}]$, where $\bar{X}_0, \cdots, \bar{X}_{n-1}$ are independent over F, has a unique representation in the form $B_0 + B_1\theta + \cdots + B_{n-1}\theta^{n-1}$, $B_i \in \mathbf{Z}[\bar{X}_0, \cdots, \bar{X}_{n-1}]$. In particular, the powers Λ^i of $\Lambda = \bar{X}_0 + \bar{X}_1\theta + \cdots + \bar{X}_{n-1}\theta^{n-1}$ may be expressed as $\Lambda^i = B_{i0} + B_{i1}\theta + \cdots + B_{i,n-1}\theta^{n-1}$, where $B_{ik} \in \mathbf{Z}[\bar{X}_0, \cdots, \bar{X}_{n-1}]$ and B_{ik} is homogeneous of degree i in $\bar{X}_0, \cdots, \bar{X}_{n-1}$. The determinant of the matrix (B_{ik}), $i, k = 0, 1, \cdots, n-1$, is a homogeneous polynomial $z(\bar{X}_0, \cdots, \bar{X}_{n-1})$ of degree $n(n-1)/2$. A second polynomial $y(\bar{X}_0, \cdots, \bar{X}_{n-1}; \theta)$ is defined, which depends on the ratios of the differents of θ and λ (the definition requires too many preliminaries to be given here), and it is shown that the norm from $F(\bar{X}_1, \cdots, \bar{X}_{n-1})$ to $\mathbf{Q}(\bar{X}_1, \cdots, \bar{X}_{n-1})$ of $y(\bar{X}_1, \cdots, \bar{X}_{n-1}; \theta)$ is $z(\bar{X}_0, \cdots, \bar{X}_{n-1})^2$. It is an immediate deduction that the following three statements are equivalent: (1) $\mathfrak{C} = \mathfrak{C}'$; (2) $z(X_0, \cdots, X_{n-1}) = \pm 1$; (3) $y(X_1, \cdots, X_{n-1}; \theta)$ is a unit in $\mathbf{Z}[\theta]$ with norm $+1$, where the $X_0, \cdots, X_{n-1}$ are rational integers. An alternative proof of these three is outlined. The results generalize and underlie observations on orders in cubic fields with which the authors introduce the paper. *J. V. Armitage* (Durham)

Fröhlich, A. 3461

On the l-classgroup of the field $P(\sqrt[l]{m})$.

J. London Math. Soc. **37** (1962), 189–192.

Let P be the field of rational numbers, l an odd prime, m is an l-power free integer ($\neq \pm 1$). Let G be the absolute class group of $K = P(\sqrt[l]{m})$ and h its order. Let e be the number of l cyclic factors of G.

Let $t = 1 +$ number of distinct prime factors of m if $(m, l) = 1$ and $X^l \equiv m \pmod{l^2}$ has no solution and $t = r$ otherwise. Let $s =$ number of distinct prime factors of m which are $\equiv 1 \pmod l$. The author proves the following

theorems: (I) $e \geq t - \frac{1}{2}(l+1)$; (II) $e \geq s$; (III) If for $i = 1, 2, \cdots, s$, and $j = 1, 2, \cdots, t$, p_j is an lth power residue mod p_i $(i \neq j)$, then $l^{s+t-(l+1)/2} | h$.

R. Ayoub (University Park, Pa.)

Birch, B. J. 3462

Waring's problem for $\mathfrak{p}$-adic number fields.
Acta Arith. **9** (1964), 169–176.

Let K be an algebraic number field and let $J(K, d)$ be the order generated by the dth powers of integers of K. Siegel conjectured that there is a number $G(d)$ such that every large enough element of $J(K, d)$ is a sum of at most G dth powers. The author proved [Proc. Cambridge Philos. Soc. **57** (1961), 449–459; MR **26** #1306] that if M is a large enough totally positive integer of K, which can be expressed as a sum of at most $s \geq 2^d + 1$ dth powers in every $\mathfrak{p}$-adic completion of K, then M is a sum of at most s totally positive dth powers of integers of K. [Cf. O. Körner, Math. Ann. **147** (1962), 205–239; MR **25** #3022; G. Rieger, ibid. **148** (1962), 83–88; MR **26** #106.] This settled the analytic part of the argument required to prove Siegel's conjecture; the arithmetic part remained open. In this paper the author proves that if $K_\mathfrak{p}$ is the $\mathfrak{p}$-adic completion of K at $\mathfrak{p}$, then every element of $K_\mathfrak{p}$ which is a sum of dth powers of integers of $K_\mathfrak{p}$ is a sum of at most d^{16d^2} such dth powers. Thus any sufficiently large totally positive element of $J(K, d)$ is a sum of at most $\max(2^d + 1, d^{16d^2})$ such dth powers.

The author proves the more general result: given any set $\mathfrak{x}$ of integers of $K_\mathfrak{p}$, then there is a set $\mathfrak{y}$ consisting of at most d^{16d^2} integers such that $s_j(\mathfrak{x}) = s_j(\mathfrak{y})$, for $1 \leq j \leq d$, where s_j denotes the elementary symmetric function of weight j. The foregoing result follows from this on expressing sums of dth powers in terms of $s_1, \cdots, s_d$. The main advantage of using symmetric functions is that one is then able to use Hensel's lemma and so pass from congruences mod $\mathfrak{p}^r$ to equalities.

For an alternate approach to the $\mathfrak{p}$-adic problem [see C. P. Ramanujam, Mathematika **10** (1963), 137–146; MR **29** #5811]. For the problem of the identification of the order $J(K, d)$, see Ramanujam [loc. cit.] and P. T. Bateman and R. M. Stemmler [Illinois J. Math. **6** (1962), 142–156; MR **25** #2059].

J. V. Armitage (Durham)

Erdős, P.; Heilbronn, H. 3463

On the addition of residue classes mod p.
Acta Arith. **9** (1964), 149–159.

Let p be a prime, $a_1, \cdots, a_k$ distinct nonzero residue classes modulo p, N a residue class modulo p. Let $F(N)$ denote the number of solutions of the congruence $e_1 a_1 + \cdots + e_k a_k \equiv N \pmod{p}$, where $e_\nu = 0$ or 1. The authors prove: (I) $F(N) > 0$ provided $k \geq 3\sqrt{(6p)}$; (II) $F(N) = 2^k p^{-1}(1 + o(1))$ provided $k^3 p^{-2} \to \infty$ as $p \to \infty$. The second result is shown to be best possible, while the first result is shown to be nearly best possible. It is conjectured that $F(N) > 0$ provided $k \geq 2\sqrt{p}$. This first result follows from elementary combinatorial arguments including the Cauchy-Davenport theorem. The proof of the second result makes use of finite Fourier series and results from diophantine approximations.

A class of quasi-fields having isomorphic additive & multiplicative groups.
J. Indian Math. Soc. (*N.S.*) **27** (1963), 71–90.

By a "quasi-field" the author means a set Q in which "addition" and "multiplication" are defined such that (1) Q together with addition is an abelian group; (2) Q together with multiplication is an abelian group (the "0" of addition is not excluded); (3) the quasi-distributive law $a(b+c) + a = ab + ac$ holds. The author constructs such quasi-fields by considering the set F of functions defined on the set $\mathscr{S}$ of finite subsets of a set S with values in a commutative ring R with unity. He then sets out to construct a logarithmic function by extending the range of F to include values in rings $R[x, y, \cdots]$. To do this he considers the function f^n and shows that for a given $S_i \in \mathscr{S}$, $f^n(S_i)$ is a polynomial of the form

$$\sum n(n-1)\cdots(n-r+1) f_r(S_i), \quad \text{where} \quad f_r(S_i) \in R.$$

He now introduces indeterminates x, y, etc., and proposes to define f^x, f^y, etc., in $R[x, y, \cdots]$ by treating $n \in \mathbf{N}$ as an indeterminate. The reviewer was unable to follow the argument at this point. The remainder of the paper is a straightforward investigation of the properties of log and exp and concludes with an account of finite quasi-fields (when S has a finite number of elements).

Mahler, K. 3465

An inequality for the discriminant of a polynomial.
Michigan Math. J. **11** (1964), 257–262.

Let $f(x) = a_0 x^m + a_1 x^{m-1} + \cdots + a_m = a_0(x - \alpha_1)\cdots(x - \alpha_m)$ be a polynomial with complex coefficients of degree $m \geq 2$, and put

$$M(f) = |a_0| \prod_{k=1}^{m} \max(1, |\alpha_k|),$$

$$P = \prod_{1 \leq h < k \leq m} (\alpha_h - \alpha_k),$$

$$Q = P \prod_{|\alpha_k| > 1} \alpha_k^{-(m-1)}.$$

The principal estimates obtained by the author are as follows. (i) Let $\alpha_r \neq \alpha_s$. Then $|Q/(\alpha_r - \alpha_s)| \leq 3^{-1/2} m^{(m+2)/2}$. This inequality is best possible except, perhaps, for the value of the constant $3^{-1/2}$. (ii) Let $D(f) = a_0^{2m-2} P^2$ denote the discriminant of f. Then

$$|D(f)| \leq m^m (M(f))^{2m-2},$$

with equality if and only if f has the form $f(x) = a_0 x^m + a_m$, where $|a_0| = |a_m| > 0$. (iii) Suppose that the zeros of f are distinct and let $\Delta(f)$ be the minimal distance between any two zeros:

$$\Delta(f) = \min_{1 \leq h < k \leq m} |\alpha_h - \alpha_k|.$$

Then

$$\Delta(f) > 3^{1/2} m^{-(m+2)/2} |D(f)|^{1/2} (M(f))^{-(m-1)}.$$

Now since, as was pointed out in an earlier paper

[Mathematika 7 (1960), 98–100; MR 23 #A1779], $M(f) \le |a_0| + \cdots + |a_n|$, the last two estimates lead to further inequalities for $D(f)$ and $\Delta(f)$, which are sometimes more useful in practice. As an application of (iii), it is shown that the imaginary part of every non-real zero of f exceeds

$$(3/4)^{1/2} n^{-(n+2)/2} \{|a_0| + \cdots + |a_n|\}^{-(n-1)}$$

in modulus. *L. Mirsky* (Sheffield)

Honda, Taira 3466

On the absolute ideal class groups of relatively metacyclic number fields of a certain type.

Nagoya Math. J. 17 (1960), 171–179.

Let $\mathfrak{G}$ be a finite group containing a subgroup $\mathfrak{H}$ with the following property: $\mathfrak{H} \cap \rho\mathfrak{H}\rho^{-1} = \{1\}$ for an arbitrary element ρ in $\mathfrak{G}$ not belonging to $\mathfrak{H}$. By the theorem of Frobenius the elements of $\mathfrak{G}$ not belonging to any conjugate subgroup of $\mathfrak{H}$, together with the identity, form a normal subgroup $\mathfrak{N}$ in $\mathfrak{G}$. The author considers the case when the groups $\mathfrak{H}$ and $\mathfrak{N}$ are both cyclic (in this case $\mathfrak{G}$ is called metacyclic of type F). Let the normal field L/P (L and P are fields of algebraic numbers of finite degree) have as Galois group a metacyclic group of type F, and let K, Ω be intermediate fields of L/P belonging to $\mathfrak{N}$ and $\mathfrak{H}$, respectively. Let $a_{L/K}$ denote the number of two-sided classes of L/K, $\mathfrak{K}_L$ the group of ideal classes of L, and $\mathfrak{K}_{L/\Omega}$ the subgroup of $\mathfrak{K}_L$ consisting of two-sided classes of the field L/Ω. The basic result of the paper is the following. If $a_{L/K} = 1$, then $\mathfrak{K}_L \cong \mathfrak{K}_{L/\Omega}^{(t)}$, the direct product of the group $\mathfrak{K}_{L/\Omega}$ taken t times, where t is the order of the group $\mathfrak{H}$. This result is used to prove the following theorem. If the class number of the cyclic field $Q(\zeta_l)$ (Q is the field of rational numbers and l is a prime) is equal to 1 and if the prime q has order $l-1$ in the group of residue classes modulo l^2, then the group of classes of the field $Q(\zeta_l, \sqrt[l]{q})$ is isomorphic to the direct product taken $l-1$ times of the group of classes of the field $Q(\sqrt[l]{q})$.

Inaba, Eizi 3467

Normal form of generalized Artin-Schreier equations.

Natur. Sci. Rep. Ochanomizu Univ. 14 (1963), 1–15.

Let k be a field of characteristic p, and M a non-singular matrix in k_n. A matrix equation (1) $X^q = MX$, where $X = (x_{ik})$ and $X^q = (x_{ik}{}^q)$ ($q = p^r$), is called a generalized Artin-Schreier equation. The author continues his study of a correspondence between the minimal Galois extension K of k which contains a solution of (1) and a representation of its Galois group $G(K/k)$ in matrices over the finite field P of q elements [same Rep. 13 (1962), no. 2, 1–13; MR 27 #5751]. In the present paper a normal form of the equation (1) is obtained by replacing M by a q-semilinear transformation T of an n-dimensional vector space over k. A general Jordan form for M is found and its characteristic polynomial is studied [see also Ore, Trans. Amer. Math. Soc. 35 (1933), 559–584; Jacobson, Ann. of Math. (2) 38 (1937), 484–507]. The reducibility of T and of the corresponding representation of $G(K/k)$ are shown to be related. This is applied to show that if k is a field containing the $(q-1)$st root of unity and satisfying the Hilbert irreducibility theorem, then k has Galois extensions with groups isomorphic to a general type of group of almost triangular non-singular matrices in P_n.

Yakabe, Iwao 3468

An extension theorem for semi-valuations of the first kind.

Mem. Fac. Sci. Kyushu Univ. Ser. A 18 (1964), 50–55.

A one-valued function $s(x)$ on the multiplicative group $\{x\} = K^*$ of a field into an additive abelian l-group Γ is called a semi-valuation if $s(xy) = s(x) + s(y)$ and $s(x+y) \ge \inf\{s(x), s(y)\}$. The semi-valuation is said to have order n if Γ has n maximal l-closed upper classes (which are sublattices of Γ); such a semi-valuation is of the "first kind". The author proves the following extension theorem. "If k is a subfield of a field K, then any semi-valuation s of the first kind of k, of order n, can be extended to a semi-valuation of the first kind of K, of the same order n. In particular, if K is a finite algebraic extension of k, then the number of distinct extensions of s in K, of order n, is finite and is not greater than d^n, where d is the degree of separability of K over k." For the proof, reference is made to the extension theorem for ordinary valuations and a reduction of semi-valuations to sets of valuations [cf. the author's papers, same Mem. 16 (1962), 1–8; MR 26 #115; ibid. 17 (1963), 10–28; MR 28 #87].

Lascu, Alexandru T. 3469

Two intersection formulas in algebraic geometry.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) 35 (1963), 435–442.

Let V be an algebraic variety, U a simple subvariety of V, and $t: V' \to V$ the monoidal transformation of center U. The author gives a formula for $X' \cdot t^{-1}(x_0)$, where $x_0 \in U$ and X' is a V'-divisor linearly equivalent to the subvariety $t^{-1}(U)$. Now suppose that U is a proper component of $A \cdot B$, where A and B are subvarieties of V, with $\mathrm{codim}_V(B) = 1$; let A', B' be the proper transforms of A and B in V'; then the coefficient of U in $t(A' \cdot B')$ is $i(A \cdot B, U; V) - m(U, A)m(U, B)$.

Sulle equivalenze e corrispondenze algebriche. II.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) 35 (1963), 486–495.

Part I appeared in Rend. Mat. e Appl. (5) 20 (1961), 338–354 [MR 25 #2064]. Let V be a complex non-singular projective variety of dimension n. For every integer h, $0 \le h < n$, the author defines a canonical cycle-class (for rational equivalence) $\Theta_h(V)$ of dimension h. For $h = 0$ one gets the Severi class (projection of the self-intersection of the diagonal in $V \times V$); for $h = n-1$ one gets the classical canonical divisor class. Relations between the cycle-classes $\Theta_h(V_i)$, $i = 0, \cdots, n$, where (V_i) is an

increasing sequence of subvarieties of V with $\dim(V_i) = i$. Application to ramified coverings $p: V \to U$.

Siegel, Carl Ludwig 3473

Moduln Abelscher Funktionen.

Nachr. Akad. Wiss. Göttingen Math.-Phys. Kl. II **1963**, 365–427.

Let $\Omega = (Z, T)$ be a $2n \times n$ period matrix, where $T = \operatorname{diag}(t_1, \cdots, t_n)$ with natural integers t_i and $Z = X + iY$ symmetric, $Y > 0$. If $t_1 \geq 3$, the Jacobian theta functions yield a singularity-free model of the corresponding Abelian manifold in the projective space of dimension $t = |T|$. Let $\vartheta_i(w) = \vartheta_i(w_1, \cdots, w_n)$ be these theta functions and consider as many indeterminates $\xi_1, \cdots, \xi_t$. With $(n+1)t$ further indeterminates λ_{ik} form $\eta_i = \sum \lambda_{ik}\xi_k$ and $j_i(w) = \sum \lambda_{ik}\vartheta_k(w)$. Now let $\Phi(\lambda, \eta)$ be a homogeneous polynomial in the λ and η of minimal degree in the latter which vanishes for $\eta_i = j_i(w)$. It has the following properties. (1) The degree is $m = n!t$. (2) If $\Phi(\lambda, \eta) = \sum \lambda_{\alpha}\Phi_{ik}(\xi)$, all algebraic equations between the $\vartheta_i(w)$ are consequences of $\Phi_{ik}(\vartheta(w)) = 0$. (3) The coefficients of Φ depend naturally on the period matrix. (4) Φ can explicitly be described as follows: let $\varphi_l(\xi)$, $l = 1, \cdots, h$, all be power products of the ξ_t in some order and $\alpha_l = \alpha_l(\lambda)$ the $(h-1)$-rowed subdeterminants of the matrix $(\varphi_l(\vartheta_k(w)))$, then

$$(1) \qquad \Phi = \sum_{l=1}^{h} \alpha_l\varphi_l(\xi).$$

The chief object of the paper is the study of the behavior of the coefficients of Φ under modular transformation of the period matrix Z (T being left fixed throughout). A tool for this is the following Hermitian scalar product of theta functions. Put $w = Zu + Tv$ with real vectors u and v and for two Jacobian functions $f(w)$, $g(w)$

$$(f, g) = \int_W f(w)\overline{g(w)}e^{(\pi/2)T(w-\bar{w})}\,du_1 \cdots dv_1 \cdots,$$

where W is the period torus. It is easily shown that the integrand is a function defined on W_1 and that two different theta functions are orthogonal while $(\vartheta_i, \vartheta_i) = 2|Y|^{-1/2}$.

Now Jacobian functions of characteristic xy are considered which are linear combinations of these theta series

$$(2) \quad \vartheta(x, y; Z, w) = \sum_m \exp \pi i(Z[m + T^{-1}x] + 2(m + T^{-1}x)^t(w + y)).$$

To these functions the transformations

$$Z_1 = (TAT^{-1}Z + TB)(CT^{-1}Z + D)^{-1},$$
$$w_1 = ((CT^{-1}Z + D)^t)^{-1}w$$

are applied, where A, B, C, D are rational integral matrices with

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}^t \begin{pmatrix} 0 & T \\ -T & 0 \end{pmatrix} \begin{pmatrix} A & B \\ C & D \end{pmatrix} = s\begin{pmatrix} 0 & T \\ -T & 0 \end{pmatrix}$$

with a further rational integer s. If $s = 1$, these matrices form the modular group $\Gamma(T)$; subsequently the following normal subgroup $\Delta(T)$ will be used:

$$(A - E)T^{-1},\ BT^{-1},\ CT^{-1},\ (D - E)T^{-1} \text{ integral.}$$

With a substitution described above and a Jacobian function $f(w_1)$ of characteristic xy and period matrix (Z_1T)

$$f_1(w) = \exp(-\pi i(s^{-1}w^tT^{-1}C^tw_1))f(w_1)$$

is a Jacobian function of characteristic

$$x_1 = A^tx + C^ty + \tfrac{1}{2}\{A^tTC\}, \qquad y_1 = B^tx + D^ty + \tfrac{1}{2}\{B^tTD\}$$

and period matrix $s(ZT)$, where $\{\cdots\}$ denotes the vector whose components are the diagonal elements of the matrix in parentheses. Furthermore, the scalar product remains invariant: $(f, g) = (f_1, g_1)$.

This transformation is specially applied to theta functions of the more general type (2) and under the restriction to $w = 0$. It yields a unitary representation of the group $\Gamma(T)$ whose coefficients can of course be written in terms of Gaussian sums. The kernel of this representation turns out to be the subgroup $\Theta(T) \subset \Delta(T)$ defined by the conditions that $AT^{-1}B^t$, $CT^{-1}D$ have even coefficients in the diagonal. A similar result which is less easy to formulate concerns the transformation of the functions (2) with $w \neq 0$; it is a decisive tool in the following problem.

Under the transformations $Z, w \to Z_1, w_1$ belonging to the modular group $\Gamma(T)$, the coefficients $\alpha_l = \alpha_l(\lambda)$ undergo corresponding transformations. The ratios $\alpha_{l_1} : \alpha_{l_2}$, however, remain invariant if and only if the transformation belongs to the congruence subgroup $\Delta(T)$. It is now very easy to form invariants for the whole modular group $\Gamma(T)$ by symmetrization. Now the α_l are polynomials in the indeterminates λ_{ik} the coefficients of which are functions of Z and the w_i. Let $q_0, q_1, \cdots, q_r$ be all these coefficients, then the quotients $f_i = q_i/q_0$ are functions of Z only. The author even proves that to every $Z = Z_0$ there is such an ordering of the q_i that the f_i are regular in the neighborhood of this point. (The statement has been somewhat simplified; in fact, this is only true if the $\alpha_l(\lambda)$ are relatively prime polynomials in the λ, the formulation of the theorem in the general case being more complicated.)

The last fact is necessary to prove the following deep theorem: All modular functions of $\Delta(T)$ are rational functions of the f_i. The proof is of course rather involved. Among other things it uses the fact that all modular functions can be represented as quotients of Eisenstein series [the author, Math. Ann. 116 (1939), 617–657; MR 1, 203]. In the case $T=tE$ it is eventually shown that all modular functions can be represented as quotients of Fourier series with integral rational coefficients.

Taking into account the contents of the author's paper quoted before [loc. cit.] (which has to be generalised, however, since it assumes $T=E$) and furthermore the result of Igusa [Amer. J. Math. 84 (1962), 175–200; MR 25 #5040], we may expect the story to end here. But the author continues, attempting to determine all algebraic equations between the functions f_i or, what is the same, all homogeneous algebraic equations between the q_i. The latter do not only depend on Z but also on the w_i. The principle of determining these equations consists of two theorems. (1) Let $Q(Z,w)$ be a homogeneous polynomial in the q_i. If sufficiently many of the initial coefficients of the development of Q in a power series in the w_i vanish, then Q vanishes identically. (2) If sufficiently many of the initial coefficients in the Fourier expansion of Q with respect to Z vanish, then Q vanishes identically. The latter theorem has been proved and used by the author on previous occasions. From these theorems we can easily derive a "constructive procedure" to obtain all algebraic relations between the f_i since we know them to be generated by those of a bounded degree. However, the conditions seem rather involved, and it may be premature to expect explicit information. *M. Eichler* (Basel)

Serre, Jean-Pierre 3474

Exemples de variétés projectives conjuguées non homéomorphes.

C. R. Acad. Sci. Paris 258 (1964), 4194–4196.

Author's summary: "Soit V une variété projective non singulière, définie sur un corps de nombres algébriques K; si φ est un plongement de K dans C, soit V_φ la variété complexe déduite de V par extension des scalaires au moyen de φ. On sait que les nombres de Betti de V_φ sont indépendants de φ. Cette propriété d'invariance ne s'étend pas au groupe fondamental: nous construisons ci-dessous une variété V et deux plongements φ et ψ tels que $\pi_1(V_\varphi)$ ne soit pas isomorphe à $\pi_1(V_\psi)$; en particulier, V_φ et V_ψ ne sont pas homéomorphes." *R. C. Hartshorne* (Cambridge, Mass.)

Ramanujam, C. P. 3475

A note on automorphism groups of algebraic varieties.

Math. Ann. 156 (1964), 25–33.

Let X be an irreducible algebraic variety and G a group of automorphisms of X. Assume that G is "connected" [i.e., any two elements of G belong to some algebraic irreducible family $S\to G$ of automorphisms) and "finite-dimensional" (i.e., for every such injective family $S\to G$, dim (S) is bounded). Then there exists on G a unique structure of algebraic groups such that the operation law $G\times X\to X$ is a morphism and is infinitesimally injective. Furthermore, for every algebraic family $S\to G$ of automorphisms of X, $S\to G$ is a morphism.

Suppose now that X is complete (more generally, that $H^0(X,F)$ is finite-dimensional for every torsion-free algebraic coherent sheaf F). Then the connected component G of Aut(X) is "finite-dimensional", and therefore admits a unique algebraic group structure, with the properties above. The group G is an extension of a subgroup of Pic (X) by a linear group.

Finally, let P be a locally isotrivial principal fiber space over a complete variety X_0. Then the connected component G of Aut (P) is an algebraic group, and the elements g of G which preserve the base X_0 form a closed subgroup of G. *P. Samuel* (Waltham, Mass.)

Linear systems of real quadratic forms.

Proc. Amer. Math. Soc. **15** (1964), 844–846.

The author gives a simple topological proof for the following theorem. Let $P(x)$, $Q(x)$ be two real quadratic forms over R^n $(x \in R^n)$, with $3 \leq n < \infty$. If the only $x \in R^n$ satisfying $P(x) = Q(x) = 0$ is $x = 0$, then there exists a linear combination of P and Q with real coefficients, that is, a positive definite quadratic form over R^n.

He remarks that the theorem is false for $n = 2$ and is partially correct for $n = \infty$. *W. Klingenberg* (Mainz)

Lynn, M. S. 3481

On the Schur product of H-matrices and non-negative matrices, and related inequalities.

Proc. Cambridge Philos. Soc. **60** (1964), 425–431.

If $A = (a_{ij})$, $B = (b_{ij})$ are $n \times n$ matrices, their "Schur product" $A \circ B$ is the $n \times n$ matrix whose (i, j)-th element is $a_{ij}b_{ij}$. Further, $A\begin{bmatrix} i_1, \cdots, i_p \\ j_1, \cdots, j_p \end{bmatrix}$ denotes the determinant of the submatrix of A specified by the rows $i_1, \cdots, i_p$ and columns $j_1, \cdots, j_p$. If $A = (a_{ij})$ is real, we define α_{ij} as $|a_{ij}|$ or $-|a_{ij}|$ according as $i = j$ or $i \neq j$, and we denote by A' the matrix (α_{ij}). The real $n \times n$ matrix A is said to be of class $\mathscr{H}_n$, a class first studied by A. Ostrowski [Comment. Math. Helv. **10** (1937), 69–96], if all principal minors of A' are positive. The main results established in the present paper are as follows. (i) If $A, B \in \mathscr{H}_n$, then $A \circ B \in \mathscr{H}_n$. (ii) If $A \in \mathscr{H}_n$, then $\det A' \leq |a_{11} \cdots a_{nn}|$. (iii) If $A \in \mathscr{H}_n$ and $1 \leq p \leq n$, then

$$\det A' \leq A'\begin{bmatrix} 1, \cdots, p \\ 1, \cdots, p \end{bmatrix} \cdot A'\begin{bmatrix} p+1, \cdots, n \\ p+1, \cdots, n \end{bmatrix}.$$

(iv) If $A, B \in \mathscr{H}_n$, then

$$\det(A \circ B)' + \det A' \cdot \det B' \geq |b_{11} \cdots b_{nn}| \det A' + |a_{11} \cdots a_{nn}| \det B'.$$

These results receive an added interest from the fact that similar conclusions are known to be valid for the class of real, symmetric, positive definite matrices. In the last section of the paper a different type of theorem is established. Let λ_A denote the spectral radius of A. Then $\lambda_{A \circ B} \leq \lambda_A \lambda_B$ for any non-negative matrices A, B; and if A, B are irreducible and at least one of them has only positive diagonal elements, then this inequality is strict. *L. Mirsky* (Sheffield)

Kazimirskiĭ, P. S. 3482

On the factorization of a polynomial matrix into linear factors. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 446–448.

Let $A(x) = \sum_{j=0}^{s} A_{s-j}x^j$, $s \geq 2$, A_j square matrices of order n $(j = 0, \cdots, s)$ with elements from an algebraically closed field P of characteristic 0, $|A_0| \neq 0$, $A_*(x)A(x) = A(x)A_*(x) = E|A(x)|$, E the unit matrix, $a_1, \cdots, a_1$ (k_1 terms), $\cdots$, $a_l, \cdots, a_l$ (k_l terms) n roots of the equation $|A(x)| = 0$, $k_1 + \cdots + k_l = n$, k_i the multiplicity of the root,

$$M_{A(x_n)} = \left\| \begin{matrix} A_*(a_1) \\ \cdot \quad \cdot \quad \cdot \\ A_*^{(k_1 - 1)}(a_1) \\ \cdot \quad \cdot \quad \cdot \\ A_*(a_l) \\ \cdot \quad \cdot \quad \cdot \\ A_*^{(k_l - 1)}(a_l) \end{matrix} \right\|.$$

Three lemmas lead to the following theorem: There exists a matrix $B(x) = B_0x + B_1$, $|B_0| \neq 0$, with the given roots and which divides $A(x)$ from the left if and only if the rank of $M_{A(x_n)}$ is n. *J. Reichbach* (Tel Aviv)

Fiedler, Miroslav 3483

Relations between the diagonal elements of two mutually inverse positive definite matrices. (Russian summary)

Czechoslovak Math. J. **14** (89) (1964), 39–51.

The results of this paper have to do with an n-by-n Hermitian positive definite matrix $A = (a_{ij})$ and its inverse $A^{-1} = (\alpha_{ij})$ and necessary and sufficient conditions on the diagonal elements. Two theorems are the following. Theorem 3.1. Let λ_1 be the least, λ_n the greatest proper value (eigenvalue) of A, $q = \lambda_n/\lambda_1$. Then

$$(\operatorname{tr} A \operatorname{tr} A^{-1})^{1/2} \geq q^{1/2} + q^{-1/2} + n - 2 \geq 2 \max \sqrt{(a_{ii}\alpha_{ii})} + n - 2,$$

where the maximum value is over all i. In the first inequality, equality is attained if and only if all remaining proper values of A are equal to $(\lambda_1\lambda_n)^{1/2}$. (Necessary and sufficient conditions for the second equality are also given.)

Theorem 3.2. For A and A^{-1} as given, it follows that

$$a_{ii} > 0, \qquad \alpha_{ii} > 0, \qquad a_{ii}\alpha_{ii} \geq 1,$$
$$\sqrt{(a_{ii}\alpha_{ii})} - 1 \leq \sum [\sqrt{(a_{jj}\alpha_{jj})} - 1]$$

for all i, where the sum is over all $j \neq i$. Conversely, let a_{ii}, α_{ii} $(i = 1, \cdots, n)$ be $2n$ real numbers which satisfy the above inequalities. Then there exists a positive definite (even real) matrix $A = (a_{ik})$ such that its diagonal elements coincide with the given numbers a_{ii} and the diagonal elements of its inverse matrix with α_{ii}.

The author also gives conditions for the equalities to hold and applications of his results.

Flagtensor algebra. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **19** (1964), no. 3, 150–152.

A flagspace is a linear space S with a sequence of subspaces $L_1 \subset L_2 \subset \cdots \subset L_n$. A flagtensor algebra is a tensor algebra for linear transformations of S which have the L_i as invariant subspaces. These can be considered relative to any structure defined in S (euclidean, non-euclidean, affine, etc.). Different definitions of flagtensors are given and their equivalence established. The invariant euclidean flagtensors are discussed.

Kozin, F. [Kozin, Frank] 3485

On functions of three vectors.

Publ. Math. Debrecen **10** (1963), 120–122.

The author proves the following theorem. Let X, Y, Z be three vector spaces, and let f be a real-valued function on $X \times Y \times Z$. The inequalities

$$\text{(I)} \qquad f(x+x_1, y+y_1, z) \geq f(x, y, z)+f(x_1, y_1, z),$$

$$\text{(I')} \qquad f(x+x_1, y, z+z_1) \leq f(x, y, z)+f(x_1, y, z_1)$$

for all vectors x, x_1, y, y_1, z, z_1 jointly imply the two opposite inequalities. The proof uses only the fact that X, Y, Z are additive abelian groups.

O. Wyler (Albuquerque, N.M.)

Kozin, Frank; Menger, Karl 3486

A self-dual theory of real determinants.

Publ. Math. Debrecen **10** (1963), 123–127.

The determinant of a square matrix is linear and alternating in rows and columns, and $\det I = 1$ if I is a unit matrix. The authors replace these postulates, for real matrices, by the following conditions: (1) det A is a sublinear and subalternating function of the columns of A, and a superlinear and superalternating function of the rows of A; (2) $\det I = 1$ is kept. {By "subalternating in columns" the following is meant. If A has two equal columns, then $\det A \leq 0$. "Superalternating in rows" means that $\det A \geq 0$ if A has two equal rows.}

O. Wyler (Albuquerque, N.M.)

Tutschke, W. 3487

Eine hinreichende Bedingung für die Existenz positiver Lösungen von linearen Gleichungssystemen.

Monatsb. Deutsch. Akad. Wiss. Berlin 5 (1963), 663–667.

The author proves a sufficient condition regarding the existence of positive solutions x_j of the linear system

$$\sum_{j=1}^{q} A_{ij}x_j = 0, \qquad i = 1, \cdots, q.$$

The result is the following. Suppose $A_{ij} > 0$ for all $i \neq j$ and let all principal minors of the matrix $\|A_{ij}\|$, $i, j = 1, 2, \cdots, n-1$, be positive numbers. From $B_i = -A_{iq} \geq 0$ it follows that $x_i > 0$ for all $i = 1, \cdots, q-1$ and $\sum_{i=1}^{q-1} B_i > 0$. The result is important in the case of applications in the theory of periodic solutions of linear elliptic partial differential equations which are not self-adjoint.

Fuchs, L.; Halperin, I. 3488

On the imbedding of a regular ring in a regular ring with identity.

Fund. Math. **54** (1964), 285–290.

When imbedding a ring A in a ring with identity by the standard method, one can replace the ring of integers by any commutative ring S with identity over which A is an algebra. Denote the resulting ring by $(A; S)$ (reviewer's notation); then A is isomorphic to an ideal in $(A; S)$. The authors show that there exists a commutative ring M with identity such that every regular ring is an algebra over M. (Regularity is used in the sense of von Neumann.) From this they deduce that any regular ring R is isomorphic to an ideal in a regular ring with identity, namely, $(R; M)$. {The proof that $(R; M)$ is regular can be shortened considerably. In fact, if E is any ring with an ideal R such that R and E/R are regular, then E is regular; see the proof of Theorem 2 in Brown and McCoy [Proc. Amer. Math. Soc. 1 (1950), 165–171; MR 11, 628].}

Gilmer, Robert W., Jr. 3489

Integral domains which are almost Dedekind.

Proc. Amer. Math. Soc. **15** (1964), 813–818.

An integral domain J with unit is said to be almost Dedekind if and only if J_P is a Dedekind domain for every maximal ideal P of J. Let D be an integral domain with unit. Theorem: D is almost Dedekind if and only if (i) nonzero proper ideals of D are maximal, and (ii) primary ideals of D are prime powers. Theorem: Let D be almost Dedekind. D is a Dedekind domain if and only if every nonzero proper ideal of D is contained in only finitely many maximal ideals. In particular, an almost Dedekind domain with only a finite number of maximal ideals is a principal ideal domain.

In terms of valuations, D is Dedekind if and only if D is a Krull domain [cf. Zariski and Samuel, *Commutative algebra*, Vol. II, p. 82, Van Nostrand, Princeton, 1960; MR **22** #11006]. Relations between the ideal structure of D and D' with $D \subseteq D' \subseteq K$ (D almost Dedekind, K its quotient field) are investigated. In particular, D' is proved to be almost Dedekind.

H. Gross (Bozeman, Mont.)

Samuel, Pierre 3490

Classes de diviseurs et dérivées logarithmiques.

Topology **3** (1964), *suppl.* 1, 81–96.

Let A be a Krull ring (i.e., a commutative ring A such that the totality $D(A)$ of divisors of A forms an ordered group whose positive elements satisfy the minimum condition), and let K be its quotient field. Let G be a cyclic group of automorphisms of A. G operates also on K. Let K' be the fixed subfield, and let $A' = A \cap K'$. Also A' is a Krull ring, and its quotient field is K'. Let $C(A)$ $[C(A')]$ be the group of divisor classes of A $[A']$. The author first studies the kernel of the canonical homomorphism $\bar{j}$ of $C(A')$ into $C(A)$ induced by the canonical map j of the divisor group $D(A')$ into $D(A)$. With a fixed generator s of G, set $h(x) = sx/x$ $(x \in K)$, and for a divisor $\mathfrak{b}$ of A' mapped by j to a principal divisor (a) of A, let $\varphi(\mathfrak{b})$ be $h(a) \bmod h(U)$, U denoting the group of units in A. φ is shown to induce a monomorphism $\bar{\varphi}$: $\operatorname{Ker}(\bar{j}) \to (U \cap \operatorname{Im}(h))/h(U)$. If every prime divisor of A' is unramified in A, then $\bar{\varphi}$ is onto. If A is factorial (i.e., $C(A) = 1$), then $\operatorname{Ker}(\bar{j}) = C(A')$. If, for instance, A is a polynomial ring $k[x_1, \cdots, x_d]$ $(d \geq 2)$ over a field k possessing a root w of 1 with exponent n prime to the characteristic of k, and if $sx_i = wx_i$, $s\kappa = \kappa$ $(\kappa \in K)$, then $\ker(\bar{j}) = C(A')$ is shown to be cyclic of order n. The same is the case if $A = k[x, y]$ and $sx = wx$, $sy = w^{-1}y$, $s\kappa = \kappa$ $(\kappa \in K)$. On the other hand, with a field k of prime characteristic p, if $A = k[x, y]$ and $s\lambda = \lambda$ $(\lambda \in k[x])$, $sy = y + x$, then A' is also factorial. Leaving these Galois descent cases, the

author turns to his main object, p-radical descent, where he considers, on assuming K to be of prime characteristic p, a derivation D of K with $D(A)\subset A$, and sets $K'=\operatorname{Ker}(D)$, $A'=K'\cap A$ (which is again Krull). As before, $j: C(A')\to C(A)$ is considered, and a monomorphism ϕ of $K(j)$ into $\mathfrak{D}/\mathfrak{D}'$ is obtained, where $\mathfrak{D}$ is the set of elements of A which are logarithmic derivatives in K and $\mathfrak{D}'$ is the set of logarithmic derivatives of units. If $[K:K']=p$ and no prime ideal of height 1 in A contains $D(A)$, then ϕ is onto. By means of the formulas of Barsotti and Cartier [Barsotti, Illinois J. Math. **2** (1958), 43–70; MR **21** #2654; Cartier, Bull. Soc. Math. France **86** (1958), 177–251; MR **21** #4957] and Hochschild [Trans. Amer. Math. Soc. **79** (1955), 477–489; MR **17**, 61], it is proved that $t\ (\in K)$ is a logarithmic derivative if and only if $D^{p-1}(t)-at+t^p=0$ with $a\in K'$, provided $[K:K']=p$. For a polynomial ring $A=k[x,y]$ (of characteristic p), cases are studied in which A' turns out to be $k[x^p, y^p, xy]$, respectively, $k[x^p, y^p, x^i+y^j]$ (i,j prime to p). In other cases, $C(A')$ is shown to be cyclic of order p, respectively, of type $(p,\cdots,p)$ and order p^f with $f<\gcd(i,j)$. For the ring $A=k[[x,y]]$ of power series, similar considerations are made to determine $C(A')$ for $A'=k[[X,Y,Z]]$ with $Z^p=XY$, respectively, $Z^2=X^{2l+1}+Y^{2l+1}$ $(p=2)$. For the last case, $C(A'[[T]])$ is also determined. The examples recover some results about factoriality in the author's paper [Bull. Soc. Math. France **89** (1961), 155–173; MR **25** #3046]. Open questions are given, including: Is $\mathfrak{D}\cap AD(A)=\mathfrak{D}'$? In case A is either a polynomial ring or a ring of power series, is $\mathfrak{D}/\mathfrak{D}'$ an algebraic group over k?

T. Nakayama (Nagoya)

Hoechsmann, Klaus 3491

Algebras split by a given purely inseparable field.

Proc. Amer. Math. Soc. **14** (1963), 768–776.

The construction of central simple algebras (of finite dimension) over a field K as a cross product (N,Γ,α) is known to hold also in the following situation [Teichmüller, Deutsche Math. 1 (1936), 92–102]: Γ is a finite group of automorphisms of a commutative ring $N=N_1\oplus\cdots\oplus N_n$ which is a direct sum of finite field extensions N_i of K, and K is the field of all elements fixed by Γ; $\alpha\in H^2(\Gamma,N^*)$ and Γ is assumed to be transitive on the set of fields $\{N_i\}$, and the identity is the only automorphism of Γ leaving all the elements of any of the fields N_i fixed. Let K be a field of characteristic p, and let E be an inseparable extension of K. Assume that E^* contains a maximal multiplicative set $X\supseteq K^*$ such that the cosets of X mod K^* form a K-linear basis of E, then the group $G=X/K^*$ (which is independent of X) is a finite group. The author proves that a K-central simple algebra A such that $(A:K)=(E:K)^2$ is split by E if and only if $A\cong(N,\Gamma,\xi)$ for some N, $\xi\in H^2(\Gamma,K^*)$ and $\Gamma\cong G$. This result is useful for all p-algebras since every p-algebra A over K has a splitting field which is inseparable over K and satisfies the preceding requirements.

S. A. Amitsur (Jerusalem)

Roquette, Peter 3492

Isomorphisms of generic splitting fields of simple algebras.

J. Reine Angew. Math. **214/215** (1964), 207–226.

Let k be a commutative field, and A a k-central simple algebra of finite dimension and of Schur exponent S. The author has defined a generic splitting field $F_m(A)$ (a Brauer field) for every multiple m of s [Math. Ann. **150** (1963), 411–439; MR **27** #4832]. The question arises under what conditions are two Brauer fields $F_m(A)$ and $F_n(B)$ isomorphic, and the following is proved. Theorem 1: If $m\geq n$ and $A\sim B^l$ for $l\geq 0$, then $F_n(A)$ is isomorphic with a subset of $F_m(B)$. The proof depends on the following interesting lemma: Let F, K be two field extensions of an infinite field k and of finite transcendence degree (tr.d.); if F is isomorphic with a subfield of a purely transcendental extension of K and $\mathrm{tr.d.}(F/k)\leq\mathrm{tr.d.}(K/k)$, then F is isomorphic with a subfield of K itself. The second result is Theorem 2: If l is prime to the exponent e of A, then $F_m(A)\cong F_m(A^l)$ if one of the following holds: (a) $m>s$, (b) $l\equiv -1 \pmod e$, (c) A has a Galois splitting field F which is cyclic over k and of degree s over k. The latter result is extended to the case that F is solvable over k. This last result covers the case of all algebras A over algebraic number fields.

{Reviewer's remark: A more general construction of $F_m(A)$ was introduced by the reviewer for the case $m^2=(A:k)$ [Ann. of Math. (2) **62** (1955), 8–43; MR **17**, 9], and there the cyclic part of case (c) of Theorem 2 was proved. This proof is asserted by the author to depend on a corollary which he claims contains an error; but in fact this proof is correct and does not depend on the quoted corollary.}

S. A. Amitsur (Jerusalem)

Bostock, F. A.; Patterson, E. M. 3493

A generalisation of Divinsky's radical.

Proc. Glasgow Math. Assoc. **6**, 75–87 (1963).

Let A be an associative ring, M a right A-module and F a set of A-endomorphisms of M closed under the circle operation: $f\circ g=f+g-fg$. An F-permissible module N is a submodule of M with the property that for every $m\in N$ there exists $f\in F$ such that $f(m)=m$. It is shown that M contains a maximal F-permissible submodule $\Delta(M,F)$ which satisfies the basic properties of a radical. This is a generalization of a radical introduced by Divinsky [Proc. Amer. Math. Soc. **9** (1958), 62–71; MR **20** #52], which is obtained for $M=A$ and F the ring of all left multiplications by the elements of the ring A. It is shown that the ascending chain condition for submodules of M, or the descending chain condition for left ideals in F, implies the existence of a $g\in F$ which leaves every element of $\Delta(M,F)$ invariant. Let $M_s(\cdot)$ denote the set of all finite-rowed matrices over $(\cdot)$ and let $P(\cdot)$ be the set of all polynomials in $(\cdot)$; then $\Delta(M_s(M), M_s(F))=M_s[\Delta(M,F)]$ and $\Delta(P(M),P(F))=P[\Delta(M,F)]$.

Kegel, Otto H. 3494

A remark on maximal subrings.

Michigan Math. J. **11** (1964), 251–255.

The following theorem is proved. If the maximal subring M of the ring R is solvable, then M is an ideal. The set of all nilpotent elements of R is a solvable ideal; it is weakly nilpotent if M is weakly nilpotent.

Z. Janko (Canberra)

Kegel, Otto H. 3495

On rings that are sums of two subrings.

J. Algebra **1** (1964), 103–109.

Let R be a ring, A and B subrings of R, and let $R = A + B$. If A and B are nilpotent, the author showed that R is also [Math. Ann. **149** (1962/63), 258–260; MR **28** #3049]. This note generalizes this result in several directions. The ideal I of R is solvably [nilpotently] embedded in R if for every epimorphism f of R such that $f(I) \neq 0$, there is an ideal J of $f(R)$ contained in $f(I)$ such that $J^2 = 0$ $[f(R)J = Jf(R) = 0]$. $S(R)$ denotes the sum of all solvably embedded ideals of R and $N(R)$ the sum of all nilpotently embedded ideals of R. These two ideals are the radicals of the two properties and behave in the usual manner. If $R = A + B$, then $N(A)N(B) = N(B)N(A) = 0 \bmod S(R)$. The author also studies an analogous situation involving descending chains of ideals, but the details are too complicated to be reproduced here. He then raises the following: (1) If $R = A + B$, is the ring generated by the Levitzki radicals of A and B locally nilpotent or at least nil? (2) If $R = A + B$, where A and B are proper subrings with nonzero Levitzki radicals, is R not simple? As a partial answer to (1) the author shows that if $R = A + B$, with A locally nilpotent, then the subring generated by A and $N(B)$ is locally nilpotent and $N(B)$ is contained in the Levitzki radical of R. *A. Rosenberg* (Ithaca, N.Y.)

Herstein, Israel N. 3496

Sul teorema di Goldie.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 23–26.

Goldie bewies, dass ein Primring, der gewisse Maximalbedingungen für Rechtsideale erfüllt, immer einen Quotientenring besitzt, der ein einfacher Ring mit Minimalbedingung ist [Proc. London Math. Soc. (3) 8 (1958), 589–608; MR **21** #1988]. Der Beweis ist von, u.a., C. Procesi vereinfacht worden [erscheint in Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **34** (1963), 372–377; MR **28** #2130]. In einer späteren Arbeit [Proc. London Math. Soc. (3) **10** (1960), 201–220; MR **22** #2627], konnte dann Goldie beweisen, dass auch ein Ring, der keine nilpotenten Ideale enthält und dieselben Maximalbedingungen erfüllt, einen Quotientenring besitzt, der ein halbeinfacher Ring mit Minimalbedingung ist. Der Verfasser gibt hier einen verhältnismässig einfachen Beweis dieser letzten Tatsache unter Benutzung des ersten obigen Resultates. Der Verfasser hofft, dass die Beweisführung von Procesi sowie die Vorliegende, die Sätze von Goldie den Studierenden der höheren Semester, mit etwaigen italienischen Kenntnissen, leicht zugänglich machen werden. Die Sätze können nämlich jetzt gleich nach den Wedderburnschen Sätzen gebracht werden.

Herstein, I. N.; Small, Lance 3497

Nil rings satisfying certain chain conditions.

Canad. J. Math. **16** (1964), 771–776.

If every element of the ring R is nilpotent, then R need not be nilpotent (not even locally, as a recent result of Golod shows), but in the presence of suitable finiteness conditions, nilpotency can be inferred. The authors conjecture that any nil ring satisfying the ascending chain condition for left annihilators is nilpotent. Without any further conditions they prove (Lemma 1) that any homomorphic image $H \neq 0$ of such a ring has an ideal $I \neq 0$ with $I^2 = 0$. This result is strengthened by aid of further conditions. Theorem 1: If the ring R satisfies the ascending chain condition on left and on right annihilators, then any nil subring of R is nilpotent. Similarly, Theorem 3: If the nil ring R satisfies the ascending chain condition on left annihilators and on direct sums of left ideals, then R is nilpotent.

In a slightly different direction they establish (Theorem 2): If the ring R satisfies a polynomial identity, R is locally nilpotent exactly if there are two nil subrings A and B of R such that $R = A + B$.

{Remark: In connection with Theorem 1, compare also J. Levitzki [Israel J. Math. **1** (1963), 215–216; MR **29** #1230].} *O. H. Kegel* (Frankfurt a.M.)

Pareigis, Bodo 3499

Einige Bemerkungen über Frobenius-Erweiterungen.

Math. Ann. **153** (1964), 1–13.

For a Frobenius extension R/S [Kasch, S.-B. Heidelberger Akad. Wiss. Math.-Natur. Kl. **1960/61**, 87–109; MR **24** #A1932; Nakayama and Tsuzuku, Nagoya Math. J. **17** (1960), 89–110; MR **23** #A1687; ibid. **19** (1961), 127–148; MR **25** #3959a; ibid. **20** (1962), 205; MR **25** #3959b], Kasch [Math. Z. **77** (1961), 219–227; MR **28** #1227] has introduced its so-called Nakayama automorphism (N.A.) as an automorphism of the centralizer $P = Z_R(S)$ of S in R. If R/S is β-Frobenius and β can be extended to an automorphism α of R, then the ring $\mathrm{Hom}(R_S, R_S)$ is α^{-1}-Frobenius over (the left-multiplication ring of) R, and the author proves first that (the centralizer of R in $\mathrm{Hom}(R_S, R_S)$ is the right-multiplication of P on R and) if ψ^* is an N.A. of R/S, then the N.A. of $\mathrm{Hom}(R_S, R_S)/R$ is given by what corresponds to $\psi^*\alpha^{-1}$ on P. Then, for $R \supset S \supset T$, he asks: Assuming that two of the extensions R/S, S/T, R/T are Frobenius, is the third one also Frobenius? For instance, it is shown that if S/T is 1-Frobenius, $T \subseteq Z_S(S)$ and R/T is β-Frobenius with the N.A. mapping S $(\subseteq Z_R(T))$ onto S, and if R_S is projective, then R/S is α-Frobenius. Finally, after Gruenberg and Kasch [cf. MR **28** #1227 cited] the notion of Spur is defined for general (non-free) Frobenius extensions, considering certain dual systems (which are not bases); and by means of the Spur the Maschke-Ikeda-Kasch characterization of relative projective and injective modules is proved for such a general case.

On ring extensions of Szép.

Nederl. Akad. Wetensch. Proc. Ser. A **67** = *Indag. Math.* **26** (1964), 40–47.

Let the additive group of a ring $\mathfrak{R}$ be a direct sum of the additive groups of two of its subrings R, P. The ring $\mathfrak{R}$

is then isomorphic to the set $\{(a, \alpha) | a \in R, \alpha \in P\}$, where addition is defined componentwise, and multiplication is given by $(a, \alpha)(b, \beta) = (ab + \alpha_l b + a\beta_r + a_l\beta + \alpha b_r + \alpha\beta)$, where α_l, β_r, a_l, b_r are homomorphisms satisfying obvious but complicated conditions. Additional restrictions on these maps are given to obtain some decomposition theorems and to provide a unit in $\mathscr{R}$. *S. A. Amitsur* (Jerusalem)

Raynaud, Michèle 3501

Solution d'un problème universel relatif aux modules projectifs de classe zéro.

C. R. Acad. Sci. Paris **258** (1964), 2457–2460.

A projective module P over a commutative ring A is of class zero if $P \oplus A^q = A^n$ for integers $q \leq n$. In this note the authors shows that the problem of finding such P can be reduced to the study of a special class of rings of the form $A_0 = Z[X_{ij}, Y_{jl}]/I$, where Z is the ring of integers and I is the ideal generated by elements of the form $\sum_i X_{ji} Y_{ik} - \delta_{jk}$ in the polynomial ring over Z. It turns out that modules P of class zero over A are obtained as $P = P_0 \otimes_{A_0} A$, where P_0 is of class zero over A_0.

Finally, the author investigates the properties of the rings A_0; they are regular, unique factorization domains. *J. P. Jans* (Seattle, Wash.)

Faith, Carl 3502

A structure theory for semialgebraic extensions of division algebras.

J. Reine Angew. Math. **209** (1962), 144–162.

Let Φ be a commutative field, $A \supset B$ $(A \neq B)$ two Φ-algebras and S a set of polynomials in $\Phi[x]$ each with a zero-free coefficient. The algebra A is an (S-) semi-algebraic (s.a.) extension of B if for every $a \in A$ there is a polynomial $f_a[x] \in S$ such that $f_a[a] \in B$. The paper deals with the problem of determining the proper s.a. extensions of an algebra B. If $A = D_n$, D a division algebra, and A is a proper s.a. extension of a subalgebra B, then D is an algebraic algebra and A itself is algebraic in each of the following cases: (1) D is commutative, (2) Φ is not countably finite, (3) B is a division ring and $\Phi \neq \mathrm{GF}[2]$. The s.a. extensions of a division algebra B are of the form $Q \oplus P$, where P is an algebraic algebra and Q is a directly irreducible semi-algebraic extension of B. In case $\Phi \neq \mathrm{GF}[2]$, then the only possible case in which $Q \neq 0$ is that Q be of characteristic p and Q is a p-radical extension of B, i.e., for every $q \in Q$, some power $q^{p^n} \in B$. Additional results are obtained from s.a. extensions of bounded degree, and some of the previous results are extended to Φ-algebras, where Φ is an arbitrary commutative ring. *S. A. Amitsur* (Jerusalem)

Faith, Carl; Utumi, Yuzo 3503

Quasi-injective modules and their endomorphism rings.

Arch. Math. **15** (1964), 166–174.

Some results on injective modules are extended to quasi-injective modules. For example, let M_R be a quasi-injective module over a ring R, S its endomorphism ring, and J the Jacobson radical of S. Then it is shown that $J = \{b \in S | M_R$ is an essential extension of ker $b\}$, S/J is a regular ring, S_S is injective if $J = 0$, and every finite set of orthogonal idempotents of S/J can be lifted to S. It is also shown that if a ring R with unity is regular or left self-injective and I is a right ideal of R, then every set $\{u_1 + I, \cdots, u_n + I\}$ of orthogonal idempotents of $R - I$ (i.e., $u_i - u_i^2, u_i u_j \in I$ for all i, j with $i \neq j$) can be lifted to R. *R. Osofsky, B. L. 3504

On ring properties of injective hulls.

Canad. Math. Bull. **7** (1964), 405–413.

Let R be a ring with unity and $\hat{R}$ the injective hull of the module R_R. It is shown by one example that $\hat{R}$ need not be a ring extension of R and by another example that $\hat{R}$ might be a ring extension of R greater than the Utumi ring of quotients of R. If $\hat{R}$ is a ring extension of R, then $\mathrm{Hom}_R(\hat{R}, \hat{R})$ is shown to be an injective $\hat{R}$-module. *R. E. Johnson* (Rochester, N.Y.)

Ioffe, L. S. 3505

The radical of a module. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 820–826.

The author introduces the radical associated with the following definition of semisimplicity for unital left Λ-modules A: $0 \notin \lambda(\Lambda - \{0\})$ implies $0 \notin \lambda(A - \{0\})$. After some preliminaries, he is concerned with conditions on Λ for the radical (in every A) to consist just of the elements of A annihilated (each) by some non-left zero divisor. His condition (sufficient and, under side conditions, necessary) is that for every λ and μ, λ not a left zero divisor, there exist ν and π, ν not a left zero divisor, such that $\nu\mu = \pi\lambda$. *J. R. Isbell* (New Orleans, La.)

Budach, Lothar; Kerstan, Johannes 3506

Über eine Charakterisierung der Grellschen Schemata.

Math. Nachr. **27** (1963/64), 253–264.

The authors give a characterization of Grell rings (noetherian integral domains of rank one) in the language of scheme theory. A subset M of the affine scheme $X = \mathrm{Spec}(A)$ is called an "absteigend" subset if any generalization of a point in M is also in M, and a subset N is called β-closed if $(N, \tilde{A}|N)$ is an affine scheme. Budach showed in an earlier paper [same Nachr. **25** (1963), 339–380; MR **28** #89] that any "absteigend" subset is β-closed if A is a Grell ring. In this paper it is shown that this property is also sufficient for a noetherian integral domain A to be a Grell ring provided A satisfies a certain condition. (This condition is shown to be superfluous by Budach [#3507 below].) *Y. Nakai* (Hiroshima)

Budach, L. 3507

Zum Begriff des Modulquotienten.

Monatsb. Deutsch. Akad. Wiss. Berlin **6** (1964), 81–85.

Let A be a commutative ring with unit and consider the category of all A-modules. For each finitely generated ideal $\mathfrak{a}$ of A, the notion of quotient functor is defined, and the most important example is the functor: $M \to \mathrm{Hom}(\mathfrak{a}, M/t(\langle\mathfrak{a}\rangle, M))$, where $t(\langle\mathfrak{a}\rangle, M)$ is the set of all m in M which are annihilated by certain powers of $\mathfrak{a}$. The author discusses also some other functors related to this. *M. Nagata* (Kyoto)

Sehgal, S. K. 3508

Jacobson theory of ringoids.

Notre Dame J. Formal Logic 4 (1963), 206–215.

A ringoid is a set R together with two partially defined binary operations that, insofar as they are defined, satisfy the axioms for a ring. For example, if $a+b$ is defined, then so is $b+a$, and $a+b=b+a$. Also, for each $a \in R$ there is $0_a \in R$ such that $a+0_a=a$ and $0_a+x=x$ whenever 0_a+x is defined. The Jacobson theory of rings is extended to ringoids, with definitions and proofs modeled on the theory for rings. In conclusion, Barratt ringoids are examined. The question is raised whether "in a general ringoid, if ab and bc are defined, then $a(bc)$ is defined".

★Struktursätze für Fastringe.

Inaugural-Dissertation zur Erlangung des Grades eines Doktors der Naturwissenschaften der Mathematisch-Naturwissenschaftlichen Fakultät der Eberhard-Karls-Universität zu Tübingen.

Paul Jllg, Photo-Offsetdruck, Stuttgart, 1963. 62 *pp.*

An additively written group Γ is an N-group for the near-ring N if and only if γn is defined in N so that $\gamma(n+m)=\gamma n+\gamma m$ and $\gamma(nm)=(\gamma n)m$ for all $\gamma \in \Gamma$ and $n, m \in N$. $\Gamma \neq \{0\}$ is (1) essentially minimal if and only if $\Gamma N \neq \{0\}$ and Γ contains only the trivial N-subgroups; (2) monogenous if and only if $\Gamma=\gamma N$ for some $\gamma \in \Gamma$; (3) strongly monogenous if and only if $\Gamma N \neq \{0\}$ and $\gamma N=\Gamma$ or $\{0\}$ for each $\gamma \in \Gamma$. The author defines four radical-like ideals in N: J_0 is the intersection of $A(\Gamma)$ of irreducible, monogenous N-groups Γ; J_1 is the intersection of $A(\Gamma)$ of irreducible, strongly monogenous N-groups Γ; J_2 is the intersection of $A(\Gamma)$ of essentially minimal N-groups Γ; D is the intersection of maximal modular right ideals of N. (Here $A(\Gamma)$ is the set of all n in N such that $\Gamma n=\{0\}$.) If the required N-groups or right ideals do not exist, then the corresponding radical is defined to be N. The author proves that $J_0 \subseteq D \subseteq J_1 \subseteq J_2$ and gives examples where $D \subset J_1=J_2$, $D=J_1 \subset J_2$, and $J_0 \subset D$. He also obtains various structure theorems for the different "semisimple" near-rings, including and generalizing results of D. W. Blackett, A. Fröhlich, R. R. Laxton, H. Wielandt, and the reviewer. Finally, he extends some results of Arens and Kaplansky on biregular rings to certain near-rings, paralleling the development in Chapter 9 of N. Jacobson's *Structure of rings* [Amer. Math. Soc., Providence, R.I., 1956; MR 18, 373].

NON-ASSOCIATIVE ALGEBRA

Sagle, Arthur A. 3510

On anti-commutative algebras with an invariant form.

Canad. J. Math. 16 (1964), 370–378.

Algebras which are anti-commutative and possess a symmetric bilinear form $f(x, y)$ such that $f(xy, z)=f(x, yz)$ for all x, y, z in the algebra are considered. Lie and Mal'cev algebras are examples of such systems. Generalizations of Lie and Mal'cev algebras are obtained by taking the non-commutative Jordan algebras $\mathfrak{A}$ of L. J. Paige [Portugal. Math. 16 (1957), 15–18; MR 20 #5795] and considering the algebras $\mathfrak{A}^-$. The anti-commutative algebra $\mathfrak{A}^0=\mathfrak{A}^-/\mathfrak{C}$, where $\mathfrak{C}$ is the set of all x in $\mathfrak{A}^-$ such that $xy-yx=0$ for each y in $\mathfrak{A}^-$, is used to construct other simple non-commutative Jordan and anti-commutative algebras. It is proved that $\mathfrak{A}^0$ is simple if and only if $f(x, y)$ is non-degenerate on $\mathfrak{A}$. It is also proved that if $\mathfrak{A}$ is any finite-dimensional, anti-commutative algebra with invariant form $f(x, y)$ over F of characteristic not 2, then there exists a non-commutative Jordan algebra $\mathfrak{B}$ with identity element 1 such that $\mathfrak{B}^-/1F$ is isomorphic to $\mathfrak{A}$. If $f(x, y)$ is non-degenerate and the mapping $x \to R_x$, where R_x is right multiplication by x, is injective, then $\mathfrak{B}$ is simple.

Martindale, Wallace S., 3rd 3511

Lie derivations of primitive rings.

Michigan Math. J. 11 (1964), 183–187.

Let R be a ring with associated Lie ring R_L. Some information has accumulated about the relation of the structure and mappings of R to those of R_L. In particular, derivations of R are R_L derivations and under severe restrictions on R may exhaust or almost exhaust the R_L derivations. The author adds to what is known in this matter as follows: If R is primitive, is not of characteristic 2, and contains a non-trivial idempotent, then R can be imbedded in a primitive ring $\bar{R}$ such that every derivation of R_L is induced by the sum of a derivation of R into $\bar{R}$ and a trace-like additive mapping sending R into the center of $\bar{R}$ and $[R, R]$ into 0.

W. G. Lister (Stony Brook, N.Y.)

Romberg, Walter 3512

Pseudobewertungen und Arithmetik in nichtassoziativen Algebren. I.

Math. Nachr. 26 (1963/64), 287–306.

Suppose that A/k is a non-associative algebra with multiplicative unit of finite rank over the field k. The author considers real-valued functions w on A, called pseudo-valuations, for which (I) $w(a)$ is finite for $a \neq 0$, $w(0)=\infty$; (II) $w(a-b) \geq \min(w(a), w(b))$; (III) $w(ab) \geq w(a)+w(b)$; (IV) given $\alpha=w(a)$ for some $a \in A$, then there exists at least one "α-w-element" $a_\alpha \in A$ such that $w(a_\alpha)=\alpha$ and $w(a_\alpha b)=\alpha+w(b)$ for all $b \in A$; (V) the restriction of w to k is a valuation, $\mathfrak{k}$ the associated residue class field. As in the associative theory of H. Benz [J. Reine Angew. Math. 209 (1962), 72–81; MR 26 #139] the valuation ring, residue class algebra $\mathfrak{R}$, ramification degree e and residue class degree f and completion are defined. If the restriction of w to k is discrete, then the customary product formula $ef=[A:k]$ for ramification and residue class degrees for complete A holds. Next, denote by $L(a)$ the left transformation $x \to ax$, $x \in A$. Suppose that $\gamma, \delta \in \{w(z), z \in A\}=\Gamma$ and for γ, δ, $\gamma+\delta$ pick w-elements π_γ, π_δ, $\pi_{\gamma+\delta}$. Then

$$w((\pi_\gamma a \cdot \pi_\delta b)L(\pi_{\gamma+\delta})^{-1}) \geq w(a)+w(b),$$

whence $\vartheta_{\gamma,\delta}(a \bmod w, b \bmod w)=(\pi_\gamma a \cdot \pi_\delta b)L(\pi_{\gamma+\delta})^{-1} \bmod w$, $w=\{z \in A,\ w(a)>0\}$ defines a two-sided distributive multiplication on the additive group $\mathfrak{R}$ considered as a $\mathfrak{k}$-module, thus giving rise to an algebra $\mathfrak{R}(\gamma, \delta)$. Normalization of the discrete value group to Γ gives rise to e^2 algebras, $0 \leq \gamma, \delta < e$, $\mathfrak{R}(\gamma, \delta)$ which make up a "w-$\mathfrak{R}$-system" $\mathfrak{S}$. This system is uniquely determined to within isotopy, i.e., different choices of the elements

π_γ, π_δ, $\pi_{\gamma+\delta}$ lead to isotopic algebras. A system $\mathfrak{S}$ is termed irreducible if a $\mathfrak{k}$-submodule of $\mathfrak{R}$ which is a two-sided ideal in all $\mathfrak{R}(\gamma, \delta)$ is necessarily equal to 0 or to $\mathfrak{R}$. The author proves that an algebra A/k is two-sided simple and each element of its center is a w-element if the associated w-$\mathfrak{R}$-system is irreducible. Furthermore, the existence of algebras A/k with prescribed w-$\mathfrak{R}$-systems $\mathfrak{S}$ is established. Finally, the general results are applied to the study of arithmetic in Cayley algebras, Jordan algebras and the lifting of idempotents (Hensel's Lemma) for complete algebras. *O. F. G. Schilling* (Lafayette, Ind.)

Oehmke, Robert H.; Sandler, Reuben 3513

The collineation groups of division ring planes. I. Jordan division algebras.

J. Reine Angew. Math. **216** (1964), 67–87.

Given a projective plane π and four points in π, no three of which are collinear, a coordinate ternary ring R may be defined. Starting with another (ordered) set of four points, the ternary ring S obtained is isomorphic with R if and only if π admits a collineation mapping one ordered set of points onto the other. Earlier results are summarized relating properties of R, each of which is a weaker condition than that R be an associative division ring, to transitivity properties of central collineations in π. The relation of isotopy between (non-associative) division rings R, S associated with planes π, π' is equivalent with isomorphism of the planes when neither R nor S is alternative. When R is a non-alternative division ring coordinatizing π, the authors study the collineation group $G(\pi)$. Among the collineations are the shears and translations; the group generated by these is the group $E(\pi)$ of elementary collineations. Those collineations which fix both of two specially chosen points form a group $H(\pi)$, and $G(\pi)=H(\pi)E(\pi)$, $E(\pi)$ being a normal subgroup. The group $H(\pi)$ may be identified with the group $A(R)$ of autotopisms of R; in this identification, the group $B(R)$ of automorphisms of R is identified with the subgroup $H_1(\pi)$ of $H(\pi)$ fixing a third point whose coordinates are $(1, 1)$. Thus the cosets of $H_1(\pi)$ in $H(\pi)$ correspond to the points in the orbit of $(1, 1)$ under $H(\pi)$. Such points (a, b) are called admissible pairs; associated with each pair is a coordinatization of π, and the pair is admissible if and only if the new coordinate ring $S_{a,b}$ is isomorphic with R. When R is a finite-dimensional (commutative) Jordan division algebra over a field of characteristic $\neq 2, 3$, the admissible pairs (a, b) are shown to be those with both a and b in Z, the center of R, i.e., all products of three elements of R involving at least one of a, b are associative. This result yields a normal subgroup $H_2(\pi)$ of $H(\pi)$, $H_2(\pi)$ being isomorphic to the direct sum $Z+Z$, with $H_1(\pi)=H(\pi)/H_2(\pi)$. A normal series for $G(\pi)$ is thus obtained, whose factors are either abelian or (in the case of one factor) the automorphisms of R.

Thedy, A. 3514

Note zu einer Arbeit von R. H. Oehmke und R. Sandler.

J. Reine Angew. Math. **216** (1964), 88–90.

The determination of admissible pairs in the paper above [#3513] is made to depend ultimately on the following: If R is a finite-dimensional simple Jordan algebra over an algebraically closed field of characteristic $\neq 2, 3$ with center Z, and if $(zm)y=z(my)$ for all $z, y \in R$, then $m \in Z$. Oehmke and Sandler prove this result by using the classification of simple Jordan algebras. The author shows that the conclusion holds for R a commutative algebra over a ring K admitting an associative linear form λ whose associated bilinear form is non-singular (thus $\lambda((ab)c)=\lambda(a(bc))$ and $\langle a, b\rangle=\lambda(ab)$ is non-singular). Unpublished work of Artin, Hel Braun and Koecher is known to the author to have established the existence of such a linear form in cases which include those needed by Oehmke and Sandler.

G. B. Seligman (New Haven, Conn.)

Kosier, Frank 3515

A generalization of alternative rings.

Trans. Amer. Math. Soc. **112** (1964), 32–42.

Rings satisfying

$$(x^2, y, z) = x \circ (x, y, z), \qquad (z, y, x^2) = x \circ (z, y, x),$$

and $(x, x, x)=0$ are studied, where $x \circ y = xy+yx$. It is known that alternative rings satisfy these identities, so that the rings studied here are generalizations of alternative rings. Rings satisfying the above three identities are shown to be power-associative. Although the decomposition of a power-associative algebra is known, a decomposition $A=A_1+A_{1/2}+A_0$ relative to an idempotent e is obtained directly, where x is in A_i if and only if $e \circ x = 2ix$. It is also proved that A_1 and A_0 are orthogonal subrings, $A_iA_{1/2}+A_{1/2}A_i \subseteq A_{1/2}$ for $i=0, 1$, $(x_i, y_{1/2}, e)=(e, y_{1/2}, x_i)$ and $x_{1/2} \circ y_{1/2}$ is in A_0+A_1 for all x_i in A_i, $i=0, 1$, and all $x_{1/2}$, $y_{1/2}$ in $A_{1/2}$. Using these results, it is proved that if A has no non-zero ideal such that $x^2=0$ for every x in the ideal, then, for some idempotent e, $A=A_{11}+A_{10}+A_{01}+A_{00}$, where x is in A_{ij} if and only if $ex=ix$, $xe=jx$. Also, $A_{ij}A_{km}=\delta_{jk}A_{im}$, except that $A_{ij}^2 \subseteq A_{ji}$ for $i \neq j$. These results and further consequences of this decomposition are used to prove that a simple ring with an idempotent $e \neq 1$ satisfying the defining identities is either an associative ring or a Cayley-Dickson algebra over its center. The fact that a semi-simple algebra has a unity element and is a direct sum of simple algebras follows from the proof of the corresponding results in Kleinfeld, Kosier, Osborn, and Rodabaugh [same Trans. **110** (1964), 473–483; MR **28** #1221]. Some examples of algebras satisfying the identities of this paper are given.

★Abelian categories. An introduction to the theory of functors.

Harper's Series in Modern Mathematics.

Harper & Row, Publishers, New York, 1964. xi + 164 pp. \$7.00.

The author of this remarkable little book evidently believes, with the reviewer, that the theory of categories and functors now exists as an autonomous part of mathematics, separate from homological algebra, and that no more excuse is necessary for the publication of a book (as opposed to a research paper) on the subject than is required for a book on point-set topology or group theory.

The book he has chosen to write has the form of a textbook and indeed devotes a considerable amount of its space to exercises. The formal exposition takes, as the author observes, a "geodesic course" towards the Mitchell embedding theorem [Mitchell, Amer. J. Math. **86** (1964), 619–637; MR **29** #4783] which asserts that a small abelian category (i.e., one with a set of objects; the index reference is to "Kittygory") may be embedded as a full exact subcategory of a category of modules.

This geodesic course leads through a chapter on fundamentals of categories, e.g., subobjects, difference kernels and completeness, and a chapter on fundamental notions for abelian categories, such as additivity, pullback and pushout diagrams (a diagram which is both is a "Doolittle" diagram) and the nine-lemma. These are followed (in Chapter 3) by considerations at the same level for functors. The next chapter gives the precise statement of the embedding theorem, proves it for complete abelian categories with projective generators, and adds some metatheorems to indicate its importance.

Chapter 5 introduces the heavy machinery, viz., the theory of functor-categories and the representation functor. Chapter 6 treats injective envelopes. Chapter 7 develops the properties of the category of left exact functors from a small abelian category into the category of abelian groups: this category is complete, abelian, has injective envelopes and an injective cogenerator, and the representation functor is a full exact embedding of the domain category into it. From these results the Mitchell theorem follows immediately.

The selection of the Mitchell theorem as the goal, and its proof as the organizing principle, of the book is perhaps somewhat idiosyncratic. On the one hand, the economy of the "geodesic course" means that the many notions introduced are very little explored. On the other, new embedding theorems, e.g., that of Gabriel and Popesco [#3518 below] are rapidly being added to the literature of the field, which is, of course, in considerable flux. Indeed, the author himself has shown [Proc. Nat. Acad. Sci. U.S.A. **49** (1963), 19–20; MR **26** #3756] that the representation embedding into the category of left exact functors has virtues not touched on in the book. But it is, no doubt, a defense against this accusation of idiosyncracy that the adoption of this organization may have been the only way of producing in finite time a book on a rapidly changing field.

Moreover, to describe this book solely in terms of its formal expository content would be grossly to misdescribe it. The exercises occupy an amount of text roughly comparable to the exposition and, indeed, are perhaps not properly labelled as exercises. They consist rather of outline treatments of large parts of category theory, which the reader is invited to fill in for himself. Thus the exercises in Chapter 2 treat the fundamentals of the theory of additive categories and the notion of group in a category. Those for Chapter 3 contain the notions of adjoint functors and the author's important existence theorem for adjoint functors, as well as an interesting application to (logical) model theory. The pace is maintained throughout: an exercise in Chapter 7 is to prove that the category of sheaves on a topological space is abelian, using the purely functor-theoretic methods developed there.

This is a "textbook" of course only for the reader of considerable mathematical maturity. For such a reader it can provide a rapid induction into this important new field.

A. Heller (Urbana, Ill.)

Popesco, Nicolae; Gabriel, Pierre 3518

Caractérisation des catégories abéliennes avec générateurs et limites inductives exactes.

C. R. Acad. Sci. Paris **258** (1964), 4188–4190.

This is an important addition to the growing family of embedding theorems for abelian categories [cf. #3517 above].

If C is a Grothendieck category, i.e., is abelian with exact direct limits, and U is a generator, then $M \to \operatorname{Hom}(U, M)$ embeds C in the category of right $\operatorname{Hom}(U, U)$ modules. The image is identified as a localization in the sense of Gabriel [Bull. Soc. Math. France **90** (1962), 323–448] with respect to a complete Serre subcategory. Thus C is equivalent to a quotient-category of the category of modules. The methods are those of the latter reference.

A. Heller (Urbana, Ill.)

You, Cheng-ye 3519

A proof of Pitcher inequalities of the critical point theory. (Chinese. English summary)

Acta Sci. Natur. Univ. Pekinensis **10** (1964), 207–210.

Author's summary: "Pitcher's proof of his inequalities

$$\bar{M}_p \geq R_p+\eta_p+\eta_{p-1},$$

$$\sum_{p=0}^{k}(-1)^{k-p}\bar{M}_p \geq \sum_{p=0}^{k}(-1)^{k-p}R_p+\eta_k \quad (k=0,\cdots,n)$$

of the critical point theory [Bull. Amer. Math. Soc. **64** (1958), 1–30; MR **20** #2648] is based on the concept of 'skeleton'. Our proof given in the present paper is simpler and closer to the usual proof of Morse's inequalities. An essential step is the following lemma. Let H_i be finitely generated modules over a principal ideal domain, $i=1, 2, 3$. If $H_1 \xrightarrow{\lambda} H_2 \xrightarrow{\mu} H_3$ is exact, then

$$R(\operatorname{Ker}\lambda)+E(H_1)+E(H_3) \geq E(H_2),$$

where $R(\operatorname{Ker}\lambda)$ is the rank of the kernel of the homomorphism λ, and $E(H_i)$ is the number of torsion coefficients of H_i. We give also an outline of another simple proof of Pitcher's inequalities by means of the universal coefficient theorem."

Drbohlav, Karel 3520

Concerning representations of small categories.

Comment. Math. Univ. Carolinae **4** (1963), 147–151.

The author obtains rather sharp results on the problem: For cardinals m, n, p, if a category has m objects and no coterminal set of n maps, is it isomorphic with a category of sets of power $<p$? The methods used are the familiar ones, which are apparently not powerful enough to solve (even) this problem completely.

J. R. Isbell (New Orleans, La.)

Yang, Kung-wei 3521

On some finite groups and their cohomology.

Pacific J. Math. 14 (1964), 735–740.

A finite group G is said to have periodic cohomology of period k if k is the least positive integer such that $\hat{H}^k(G, Z)$ contains a maximal generator. The following proposition is proved. Let G be a finite group whose 2-Sylow subgroups are not isomorphic to a generalized quaternion group. Then G has periodic cohomology of period 4 if and only if G has a representation

$$G = \{\sigma, \tau : \sigma^s = 1, \tau^t = 1, \tau\sigma\tau^{-1} = \sigma^{-1}\}$$

with the conditions (i) s is an odd integer > 1; (ii) t is a positive even integer prime to s [Cartan and Eilenberg, *Homological algebra*, pp. 260–265, Princeton Univ. Press, Princeton, N.J., 1956; MR 17, 1040]. Further, it is shown that all possible cohomologies of such a group G can be realized by direct sums of G-modules which belong to a specific finite family of G-modules. *K. Kondo* (Tokyo)

Ozeki, Hideki 3522

Chern classes of projective modules.

Nagoya Math. J. 23 (1963), 121–152.

L'auteur définit les classes de Chern d'un module projectif M de type fini et de rang constant sur une algèbre commutative R. Ces classes sont des éléments des modules de cohomologie de R donnés par le complexe des formes multilinéaires alternées sur le module des dérivations de R. La définition utilise une connexion linéaire dans M et repose sur la formule qui exprime les classes de Chern d'un espace fibré vectoriel complexe à partir de la forme de courbure associée à une connexion. L'auteur démontre que les classes ainsi définies ne dépendent pas de la connexion choisie et vérifient la formule du produit pour la somme directe de deux modules.

J. L. Koszul (Grenoble)

Cartier, P. 3523

Sur l'acyclicité du complexe des formes différentielles.

Ann. Scuola Norm. Sup. Pisa (3) 16 (1962), 45–74.

The author proves the Poincaré and Grothendieck lemmas, and their analogues for flows, on the basis of the following two simple algebraic theorems. On the Abelian group M let there be given a system of operators D_i $(1 \le i \le n)$ which commute pairwise, and introduce the differential $d = \sum_{i=1}^n d_i$ into the Z-module $C = M \otimes E$ (where E denotes the exterior algebra over the free Abelian group Z^n with generators $e_1, \cdots, e_n$), where

$$d_i(m \otimes u) = (D_i m) \otimes (e_i \wedge u), \qquad m \in M,\ u \in E.$$

Let us set

$$M_0 = (0), \quad M_i = \sum_{j=1}^{i} D_j(M), \qquad i = 1, \cdots, n.$$

If D_{i+1} induces an injective mapping on M/M_i for every i, $0 \le i < n$, then $H^p(C) = 0$ for $p \ne n$ and $H^n(C) = M/M_n$.

The second theorem is a duality theorem. Let

$$M_0' = M, \quad M_i' = \bigcap_{j=1}^{i} \operatorname{Ker} D_j, \qquad i = 1, \cdots, n.$$

If the operator D_{i+1} is surjective on M_i' for every i, $0 \le i < n$, then $H^p(C) = 0$ for $p \ne 0$, and $H^0(C) = M_n'$.

Deuxième édition. Collection Universitaire de Mathématiques.

Dunod, Paris, 1964. vii+401 *pp*. 36.00 *F*.

Contents: (I) Lois de composition; (II) Demi-groupes, groupes; (III) Génération des groupes; (IV) Anneaux, corps; (V) Ensembles ordonnés, treillis; (VI) Axiome de Zorn; (VII) Anneaux noethériens; (VIII) Compléments de théorie des groupes; (IX) Espaces vectoriels; (X) Corps, équations algébriques.

This work was written as a textbook for an already existing course, the content of which was apparently preordained. Possibly for this reason the book is somewhat conservative; indeed, it really could have been written twenty years ago. Nevertheless, it is good. As one would expect from the authors, unusual attention is given to the study of general multiplicatively closed systems. This helps give the book its unique character and effectively illustrates the use of the basic axioms. The style is severe, light on motivation, and with some tendency to prove things in settings considerably more general than their main realm of applicability would justify to many people. Criticism of content would be unfair without knowledge of the specific course for which the book is intended. Suffice it to say that what the book does, it does well and with style.

Grindlinger, M. D. [Greendlinger, Martin D.] 3526

On Magnus's generalized word problem. (Russian)

Sibirsk. Mat. Ž. 5 (1964), 955–957.

Let $G = \mathrm{Gp}\{X; \Phi\}$ be a finitely presented group, and for any subset X' of X, denote by H the subgroup of G generated by X'. By Magnus's generalized word problem the author understands the problem of finding an algorithm for deciding when a given word w in X belongs to H (this was solved by Magnus [Math. Ann. 106 (1932), 295–307] when Φ consists of a single relation). Assume that (i) $\Phi = \{R_1, \cdots, R_m\}$ is closed under taking inverses and cyclic conjugates; (ii) each R_i is reduced as a free word; (iii) if $R_i \ne R_j^{-1}$, then cancellation in R_iR_j absorbs less than one-sixth the length of R_i. When these conditions hold and when the left-hand half of each R_i (including

the middle letter, if any) includes a letter not in X', the author gives such an algorithm in explicit form.

Grindlinger, E. I. 3527
Solution of the isomorphism problem for a class of semigroups. (Russian)
Sibirsk. Mat. Ž. **5** (1964), 768–792.
The isomorphism problem is solved for a special class of semigroups given by a finite number of generators and relations. Calling a "defining word" the left or right side of one of the defining relations, we can state the condition as follows: no defining word is a proper part of another defining word.

This class includes the class for which the author had solved the word problem [same Ž. **5** (1964), 77–85; MR **28** #3079]. He remarks that he does not known whether the word problem is solvable in the whole class under consideration. *S. Stein* (Davis, Calif.)

Corrigendum: "Existence of unrestricted direct products with one amalgamated subgroup".
J. London Math. Soc. **39** (1964), 672.
A correction to a recent paper [same J. **38** (1963), 169–175; MR **26** #6232] in which the proof of part (b) of Theorem 2.3 is replaced.

Oyama, Tuyosi 3529
On the groups with the same table of characters as alternating groups.
Osaka J. Math. **1** (1964), no. 1, 91–101.
The author proves the following: A finite group G which has the same table of characters as an alternating group A_n is isomorphic to A_n. By an elaborate examination of the multiplication table of conjugate classes in G, he shows the existence of elements $a_1, \cdots, a_{n-2}$ in G which satisfy the relations $a_1^3=1$, $a_2^2=\cdots=a_{n-2}^2=1$, $(a_ia_{i+1})^3=1$, $(a_ia_j)^2=1$ for $j>i+1$. The argument is more or less similar to that used by the reviewer in proving the similar theorem for a symmetric group [J. Inst. Polytech. Osaka City Univ. Ser. A **8** (1957), 1–8; MR **19**, 387]. The first two lemmas in the paper are used effectively to determine the orders of elements in some conjugate classes.

Ito, Noboru 3531
On transitive permutation groups of prime degree. (Japanese)
Sûgaku **15** (1963/64), 129–141.
In the first half of the paper, the author gives an excellent exposition of the main problems in the investigation of transitive groups of degree p (p a prime) and several methods which have been used or will be useful for them. Then the following two theorems concerning the solvability of transitive groups of degree p are proved. (1) Let G be a transitive group of degree p and let H be the subgroup of G fixing one letter. If the center of H is not trivial, then G is solvable. (2) Let G be as above. If each irreducible representation of G has degree prime to p, then G is solvable. ((1) has also been obtained by Wielandt independently.) Finally, the author sketches the proof of the following main theorem. A non-solvable transitive group of degree $p=2q+1$, where p and q are both prime, is triply transitive if $p>11$. *H. Nagao* (Osaka)

Learner, A. 3532
Residual properties of polycyclic groups.
Illinois J. Math. **8** (1964), 536–542.
It is proved that if G is polycyclic, there exists a finite set π of primes such that G is residually a finite π-group. In fact, let $G=G_0>G_1>\cdots>G_k=1$ be a normal series for G with factors finite or free abelian, and let τ be a finite non-empty set of primes including all primes dividing the orders of finite factors of this series. Let ω be the product of the primes in τ. Then as π one may take τ, together with all primes dividing the index of the centraliser of G_{i-1}/G_i whenever G_{i-1}/G_i is finite, and all primes dividing the index of the centralizer of $G_{i-1}/G_iG_{i-1}^{\omega}$, whenever G_{i-1}/G_i is infinite. *Graham Higman* (Oxford)

Kohler, Joseph 3533
Finite groups with all maximal subgroups of prime or prime square index.
Canad. J. Math. **16** (1964), 435–442.
A theorem of Huppert [Math. Z. **60** (1954), 409–434; MR **16**, 332] says that if every maximal subgroup of a finite group G is of prime index, then every chief factor of G is of prime order. One of the main results of this paper is a generalization of the above theorem to finite groups with the property that every maximal subgroup is of prime or prime square index (property M). The author proves that if G is a finite group with property M and if the order $|G|$ of G is odd, then every chief factor of G is of prime or prime square order. The oddness of $|G|$ is shown to be necessary by constructing a group of even order with the property M that has a chief factor of order greater than a given number.

The following two theorems are also proved. (1) Let $\Delta(G)$ be the intersection of the non-normal subgroups of G. A finite group G has property M if and only if $G/\Delta(G)$ is a subdirect product of primitive solvable permutation groups on a prime or a prime square number of letters. (2) If $|G|$ is not divisible by 6 and if every maximal subgroup of G has the property M, then G is solvable.
B. Chang (Vancouver, B.C.)

Bauman, S. 3534
Nonsolvable IC groups.
Proc. Amer. Math. Soc. **15** (1964), 823–827.
Two subgroups H and K of a group G are said to be non-incident if $H\not\subset K$ and $K\not\subset H$. A finite group G is said to

be an IC group if for any two non-incident subgroups H and K, $H \cap K$ has only cyclic Sylow groups. The author proves that if G is a nonsolvable IC group then G is isomorphic to one of the following: (i) SL(2, 4), (ii) SL(2, 8), (iii) SL(2, 5).

D. L. Barnett (Dayton, Ohio)

Balcerzyk, S. 3535

On groups of functions defined on Boolean algebras.

Fund. Math. **50** (1961/62), 347–367.

Let G be an Abelian group of cardinality $\mathfrak{m}$ and $\mathscr{B}$ a Boolean $\mathfrak{m}$-additive algebra with maximal element e. The group $S(\mathscr{B}, G)$ is defined by the set of functions x defined on G and satisfying the following conditions. (1) $x(g) \in \mathscr{B}$ for all $g \in G$. (2) $\bigcup_{g \in G} x(g) = e$. (3) $x(g) \cap x(g') = 0$ for $g \neq g'$. The sum $z = x + y$ of two such functions x and y is defined by the equation $z(g) = \bigcup_{g' \in G} (x(g') \cap y(g - g'))$ for $g \in G$. For each element x of $S(\mathscr{B}, G)$, put $\nu(x) = \bigcup_{0 \neq g \in G} x(g)$. Let $\mathscr{J}$ be an arbitrary (finitely additive) ideal in the algebra $\mathscr{B}$ and $\mathscr{J}_\delta$ the least σ-ideal containing $\mathscr{J}$. The set $S(\mathscr{J})$ is defined by all elements $x \in S(\mathscr{B}, G)$ with $\nu(x) \in \mathscr{J}$. Then, it is a subgroup of $S(\mathscr{B}, G)$.

The author studies the structure of the factor groups $S(\mathscr{J}_\delta)/S(\mathscr{J})$ for the torsion-free group G. He proves that they are torsion-free algebraically compact groups (in the sense of Kaplansky). In a special case, he gives the cardinal invariants of these groups. The homomorphism groups of groups $S(\mathscr{B}, G)$ in slender groups are also studied. (The author communicated some of the results in an earlier paper [Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. 7 (1959), 141–142; MR **21** #7245].)

Yahya, S. M. 3536

Kernel of the homomorphism $A' \otimes B' \to A \otimes B$.

J. Natur. Sci. and Math. **3** (1963), 139–145.

Let $\phi: A' \to A$ and $\psi: B' \to B$ be monomorphisms of abelian groups. The author considers the question of whether the kernel K of the homomorphism

$$\phi \otimes \psi: A' \otimes B' \to A \otimes B$$

is generated by monomials $a' \otimes b'$, $a' \in A'$, $b' \in B'$. He gives two examples, one for mixed groups, and another for finite groups, to show that the answer is not always yes. He gives also some sufficient conditions for the answer to be affirmative. For example, if ϕ is an epimorphism, or if $\phi(A')$ contains the torsion subgroup of A, or if both A and B are divisible, then K is generated by monomials of the form $a' \otimes b'$, where either $\phi(a') = ha$, and $hb' = 0$, or $\psi(b') = hb$, and $ha' = 0$.

Šemetkov, L. A. 3537

Subgroups of π-supersoluble groups. (Russian)

Dokl. Akad. Nauk BSSR **8** (1964), 495–496.

A group is called π-supersoluble if it possesses a principal series with cyclic π-quotients and (arbitrary) π'-quotients. A group is of type S if it is not nilpotent while all the proper subgroups are. The author shows: If R is the maximal normal π'-subgroup of the π-supersoluble group G, then (i) G/R is the extension of its π-Sylow group by an abelian group; (ii) for all primes p of π' dividing $o(G/R)$ there are p-nilpotent pq-subgroups of type S in G for a certain prime q in π with $q \equiv 1 \bmod p$. Two further theorems are interesting corollaries.

H. Heineken (Frankfurt a.M.)

Feit, Walter; Thompson, John G. 3538

Solvability of groups of odd order.

Pacific J. Math. **13** (1963), 775–1029.

In this impressive paper, which occupies the entire issue, the authors present a complete proof of the solvability of finite groups of odd order; thus they give an affirmative answer to the famous Burnside conjecture that all finite non-abelian simple groups are of even order. Not only the result itself, which has many consequences of importance, but the method employed, is significant. It is difficult to state an indication of their long involved proof and explain the reason why the oddness of the group order implies the solvability. The oddness of the group order predominates the proof and is used in all sorts of conceivable ways. The reviewer makes no attempt here to indicate the places in the proof where the oddness of the order is essential.

If there were a non-solvable group of odd order, then a non-solvable group of the smallest possible odd order would be a non-abelian simple group, all of whose proper subgroups are solvable. Such a simple group is called a minimal simple group. The proof of this paper consists in deriving a contradiction from the assumed existence of a minimal simple group of odd order. The proof is an expansion of ideas contained in papers by the reviewer [Proc. Amer. Math. Soc. **8** (1957), 686–695; MR **19**, 248] and Feit, Hall and Thompson [Math. Z. **74** (1960), 1–17; MR **22** #9539], where special cases of Burnside's conjecture are solved. In these papers special assumptions are placed on the structure of the centralizers, and the minimal simple group to be disposed of satisfies the property that every maximal subgroup is a Frobenius group and is the normalizer of a nilpotent Hall subgroup. From this property one can apply the theory of group characters, the theory of so-called exceptional characters, which provides a certain limitation on the index of a nilpotent Hall subgroup in a maximal subgroup. One is then able to derive a contradiction if the order of the group involved is odd. Chapter V of this paper is an application of group characters. In the general case of this paper, maximal subgroups may not be Frobenius groups, so that the theory of exceptional characters has to be generalized to take care of situations which may occur in the present case. This generalization is given in Chapter III of this paper. The details are too technical to be presented here, but roughly speaking, given a subgroup H which is "nicely" imbedded in G and given a set S of generalized characters of H which satisfies "nice" properties, one can define a particular isometry τ of S into the ring of generalized characters of G. This makes it possible to study the ring of generalized characters of G by means of $\tau(S)$; thus one obtains a certain information on the structure of G from the structure of H. In Chapter III the authors discuss a tamely imbedded (i.e., "nicely" imbedded) subset, of which H is the normalizer, and a coherent set of characters of H, which is "nice". A particular mapping τ is defined for a coherent set. The main discussion is to find a sufficient condition for a union of several coherent sets to be coherent. Theorem 10.1 is a main result in this direction and is a generalization of a

result of Brauer and Feit on exceptional characters [cf. Feit, Illinois J. Math. 4 (1960), 170–186; MR 22 #4784]. The coherency of a certain set often comes from the structure of H. Chapter III contains several results of this nature. All results in this chapter are of a general character and do not refer to a minimal simple group of odd order. In Chapter V, the ring of generalized characters of G is studied by using $\tau(S)$ for certain coherent sets S of generalized characters of various maximal subgroups. A delicate discussion about a not necessarily coherent set comes in also. After about seventy pages of computation, the outcome is not quite a contradiction. But one obtains a contradiction unless there are two maximal subgroups of a special kind, which are interrelated in a particular fashion. These two groups generate G. Their structure and the way they intersect give rise to relations among the set of generators of G. The final chapter, Chapter VI, is a study of these generators and relations (about twenty pages). The authors are then able to show that the particular relations they obtain are not possible in finite groups. One of the distinguished maximal subgroups is isomorphic to an extension of the linear group $y = ax + b$, where a, b are elements taken from a finite field with a restriction that the norm of a over the prime field is 1. From this fact the authors are able to translate the relations among generators into equations in a finite field and then derive a desired contradiction.

Chapter IV is a study of maximal subgroups by means of group-theoretical methods, and the main object is to show that maximal subgroups satisfy nice properties so as to make possible an application of group characters. Here the method the authors employ is quite interesting. Many parts of their argument can be and have been generalized to handle minimal simple groups in general or simple groups in which every proper subgroup involves only a particular class of simple groups [see the work of D. Gorenstein and J. H. Walter in J. Algebra 1 (1964), 168–213].

Let p be a prime divisor of the order of G and S a Sylow p-group of G. Let A be a maximal abelian normal subgroup of S. Assume that the minimal number of generators of A is at least three. The study of subgroups U such that U is normalized by A and $U \cap A = \{1\}$, is important. The first major result is the following transitivity theorem (Theorem 17.1). Let q be a prime different from p. If Q_1 and Q_2 are two q-subgroups, normalized by A and maximal under this restriction, then there is an element x of $C_G(A)$ such that $Q_2 = x^{-1}Q_1x$. This transitivity theorem is true if G is a p-solvable group. Even in the solvable case, this is not quite trivial and is one of the many results the authors have to establish in their course of proof. The fact that this result holds for minimal simple groups is amazing. In this theorem, not only the conjugacy of Q_1 and Q_2, but also the location of the element x which conjugates Q_1 and Q_2, is important. The second step is to prove the existence of a Hall subgroup with respect to a particular set of primes. Let a set of primes π satisfy the property that if p and q are two primes in π, then G contains a proper (hence solvable) subgroup generated by elementary abelian subgroups of order p^3 and q^3, respectively. The existence theorem asserts that if π satisfies the above property, then G contains a Hall π-subgroup. The passage from the transitivity theorem to this existence theorem is not short (about fifty pages) and represents one of the highest points ever achieved in the theory of finite groups. The proof is quite technical and involved. The prime p such that a Sylow p-group does not normalize any p'-subgroup has to be treated separately, but at the end G has a Hall π-subgroup H such that $N_G(H)$ is a maximal subgroup and the intersection of H and its conjugate H^x is not too large.

If a Sylow p-group S does not contain an elementary abelian normal subgroup of order p^3, the structure of S is restricted (and in fact for $p > 2$ a complete classification is available [Blackburn, Acta Math. 100 (1958), 45–92; MR 21 #1349; Proc. London Math. Soc. (3) 11 (1961), 1–22; MR 23 #A208]). This and the above existence theorem are used to study maximal subgroups of G, which are proved to have a structure closely related to Frobenius groups. Another result is that two elements of a nilpotent Hall subgroup H of G are conjugate in G if and only if they are conjugate in the normalizer of H. Also, one has to know that certain sets are tamely imbedded before one is able to apply character theory. The required proof occupies the long last section of Chapter IV (about forty pages).

Chapters I and II are preliminaries, and contain many new properties of finite groups, the importance of which is recognized by the success of this work.

M. Suzuki (Urbana, Ill.)

Šmel'kin, A. L. 3539

Wreath products and varieties of groups. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1063–1065.

The "base group" of a wreath product of two groups is a direct power of the first group; if this is replaced by a verbal power, the corresponding construction yields a "verbal wreath product". Theorem 1 is a technical result on verbal wreath products. It enables the author to re-prove some theorems of G. Baumslag [Math. Z. 81 (1963), 286–299; MR 27 #1503], e.g., (Theorem 2) that if N is a normal subgroup of a free group F and $V(N)$ is a verbal subgroup of N, and if both F/N and $N/V(N)$ are residually finite (residually finite p-groups), then so is $F/V(N)$. Further applications include Theorem 3. Let F, N, $V(N)$ be as above; let F have finite rank, let N be generated (qua normal subgroups of F) by a recursively enumerable set of elements, and let the verbal subgroup function V be defined by a recursively enumerable set of words. The word problem is solvable in $F/V(N)$ if it is solvable in F/N and in the countable rank free group of the variety associated with V. Theorem 4. The product of two non-trivial varieties can be generated by a finite group if and only if the first variety is nilpotent, the second is abelian, and their exponents are relatively prime positive numbers. This solves a problem for which a partial solution had been given by P. M. Neumann [Quart. J. Math. Oxford Ser. (2) 14 (1963), 46–50; MR 27 #1523]. *L. G. Kovács* (Canberra)

Kemhadze, Š. S. 3540

On outer nilpotent automorphism groups. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **34** (1964), 265–270.

The automorphism σ of the arbitrary group G is called stable or outer nilpotent if σ induces the identity in each factor of some finite normal series of G [see B. I. Plotkin, Dokl. Akad. Nauk SSSR **130** (1960), 977–980; MR 22

#A228]. The author proves that the set of elements of G inducing stable inner automorphisms in G coincides with the Baer nilradical $N(G)$ which is the maximal normal nilsubgroup of G. If σ is a stable automorphism of G and $g \in G$, then $[g, \sigma] = g^{-1}g^{\sigma} \in N(G)$.

H. Salzmann (Frankfurt a.M.)

Kemhadze, S. S. 3541

On stable groups of automorphisms. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 510–512.

A set Φ of automorphisms of a group G is called stable if G has an ascending normal series of Φ-admissible subgroups such that every element of Φ induces the identity automorphism on every factor of this series. A subset of G is stable if the corresponding set of inner automorphisms is stable. A single automorphism (or element) of G is stable if the corresponding one-element set is stable. A group is quasi-nilpotent if every finitely generated subgroup of it is subnormal; the quasi-nilpotent radical of a group is the union of its quasi-nilpotent normal subgroups [the author, same Dokl. **155** (1964), 1003–1005; MR **28** #3098]. If G, Φ are as above, then $[G, \Phi]$ denotes the subgroup generated in G by the elements $g \cdot \sigma g$ where $g \in G$, $\sigma \in \Phi$, $\sigma: g \to \sigma g$.

Theorem 1: In any group G, the set of all stable elements coincides with the quasi-nilpotent radical. Theorem 2: The subgroup generated by a finite subset A of a group G is contained in the quasi-nilpotent radical of G if and only if A is stable. Theorem 3: If Φ is a stable group of automorphisms of G, then $[G, \Phi]$ is contained in the quasi-nilpotent radical of G. Theorem 4: Let Φ be any group of automorphisms of a group G. The set of those stable automorphisms of G which lie in the locally nilpotent radical of Φ is a normal subgroup of Φ. Seven corollaries are given.

L. G. Kovács (Canberra)

Baer, Reinhold 3542

The hypercenter of functorially defined subgroups.

Illinois J. Math. **8** (1964), 177–230.

In this paper a functor $\mathfrak{f}$ on a suitable class $\mathfrak{D}$ of groups is a rule assigning to each group G in $\mathfrak{D}$ a subgroup $\mathfrak{f}G$, such that if σ is a homomorphism of G into H, $(\mathfrak{f}G)^{\sigma} \subseteq \mathfrak{f}H$, with equality if σ is an epimorphism. Furthermore, $\mathfrak{f}$ is an n-functor, where n is a positive integer, if for all G, $\mathfrak{f}G$ is the join of the groups $\mathfrak{f}U$, where U runs over the n-generator subgroups of G. For instance, the nth term of the lower central series is an n-functor on the class of all groups; and (using the well-known but not yet available determination by J. G. Thompson of all minimal simple groups) the intersection of the terms of the derived series is a 2-functor on the class of finite groups.

Using his own characterisations of Engel elements in Noetherian groups [Math. Ann. **133** (1957), 256–270; MR **19**, 248], the author first proves that if $\mathfrak{f}$ is an n-functor and $\mathfrak{f}G$ is Noetherian, then (a) $\mathfrak{f}G$ is nilpotent of finite class if $\mathfrak{f}U$ is of finite class for every $(n+1)$-generator subgroup U of G, and (b) $\mathfrak{f}G$ is contained in the hypercenter of G if, for every $(n+1)$-generator subgroup U of G, $\mathfrak{f}U$ is contained in the hypercenter of U. He then discusses conditions under which, in the first of these statements, $n+1$ can be replaced by n. If $n>1$ and G is assumed finite, a painstaking analysis of the least criminal yields a list of conditions too complicated to be reproduced here. From these, it is deduced that if $\mathfrak{f}$ is an n-functor with $n>1$, and $\mathfrak{f}G$ is finite, then $\mathfrak{f}G$ is nilpotent if and only if (a) for all n-generator subgroups U of G, $\mathfrak{f}U$ is nilpotent and (b) for all subgroups S ($\neq G$) of $\mathfrak{f}G$, $S/\mathfrak{f}S$ is soluble. There is a similar result if $\mathfrak{f}G$ is only assumed to be Noetherian, (b) being replaced by the requirement that $\mathfrak{f}G$ is soluble.

The author turns next to the hypercenter of $\mathfrak{f}G$. The normal subgroup N of G is said to be $\mathfrak{f}$-hypercentralized if $N \cap \mathfrak{f}G$ is contained in the hypercenter of $\mathfrak{f}G$, and $\mathfrak{f}$-n-hypercentralized if $N \cap \mathfrak{f}U$ is contained in the hypercenter of $\mathfrak{f}U$ whenever U is a subgroup of G generated by $n+1$ elements, at least one of which is in U. An $\mathfrak{f}$-hypercentralized normal subgroup is $\mathfrak{f}$-n-hypercentralized for all n, and if $\mathfrak{f}$ is an n-functor, $n>1$, an $\mathfrak{f}$-$(n+1)$-hypercentralized normal subgroup is $\mathfrak{f}$-hypercentralized. Various additional hypotheses are given under which, in this last statement, $\mathfrak{f}$-$(n+1)$-hypercentralized can be replaced by $\mathfrak{f}$-n-hypercentralized.

The paper contains also a number of variations of the ideas here mentioned, and numerous counterexamples.

Graham Higman (Oxford)

Baer, Reinhold 3543

Erreichbare und engelsche Gruppenelemente.

Abh. Math. Sem. Univ. Hamburg **27** (1964), 44–74.

A normal chain in a group is a set of subgroups which is well-ordered by inclusion, which contains the union of each of its subsets, and each member of which, except the last, is normal in its successor. The subgroup U of the group G is accessible if there is a normal chain to which both U and G belong. If $\mathfrak{e}$ is any group property, and if G is any group, $\mathfrak{e}G$ denotes the join of the accessible $\mathfrak{e}$-subgroups of G. This paper is mainly concerned with the two questions (i) whether $\mathfrak{e}G$ is necessarily an $\mathfrak{e}$-group, and (ii) whether $\mathfrak{e}(G/\mathfrak{e}G)$ is necessarily 1.

First, the author obtains an abstract characterization of properties $\mathfrak{e}$ for which the answer to both questions is positive. This is so, for instance, if $\mathfrak{e}$ is the property of being locally nilpotent, or of possessing a normal chain containing 1 and G with cyclic factors.

If, however, $\mathfrak{e}$ is the property of being locally noetherian, the answer to (i) is positive but to (ii) is negative. This suggests the study of the property of possessing a normal chain, including 1 and G, with locally noetherian factors. Because a join of accessible locally noetherian subgroups is locally noetherian, this is equivalent to asking that non-trivial homomorphic images of G have a non-trivial locally noetherian normal subgroup. The new property proves useful in the study of classes of elements defined by variations on the Engel conditions.

Baer, Reinhold 3544

Der reduzierte Rang einer Gruppe.

J. Reine Angew. Math. **214/215** (1964), 146–173.

The rank of a group is the smallest number of elements required to generate it, and the reduced rank is the smallest number of conjugate classes of elements required to generate it, with the convention that both the rank and the reduced rank of a trivial group are 1. If the group is finite, then its reduced rank is the rank of its factor group by the derived group, and the purpose of this paper

is to obtain conditions on an infinite group which ensure the same equality.

The normal subgroup N of the group G is said to be small if there is no proper normal subgroup X of G such that $G=NX$. The union of all small normal subgroups of G is also the intersection of all maximal normal subgroups of G, and is here called the radical of G. Then the result proved is that if the radical of G is itself a small normal subgroup, and if the minimal condition holds for the normal subgroups of G between the derived group and its intersection with the radical, then the reduced rank of G is the rank of G/G'.

The paper also contains interesting characterisations of the group properties of having rank or reduced rank less than a fixed cardinal; and of the groups which are direct products of a finite number of simple groups, or of simple groups and free cyclic groups. *Graham Higman* (Oxford)

Kirsch, Arnold 3545

Über die Endomorphismen der endlichen Bewegungsgruppen und ihre Veranschaulichung.

Math.-Phys. Semesterber. **11** (1964), 48–70.

The author observes that, whenever a finite rotation group $\mathfrak{G}$ has a normal subgroup $\mathfrak{N}$, it also has a subgroup isomorphic to the quotient group $\mathfrak{G}/\mathfrak{N}$. He illustrates this fact by drawing a figure which $\mathfrak{G}$ leaves invariant and decorating it with a pattern which is invariant for $\mathfrak{N}$ but is changed by every element (except the identity) of the other subgroup. For instance, if $\mathfrak{G}$ is the octahedral group and $\mathfrak{N}$ its tetrahedral subgroup, the figure is a cube and the pattern is an inscribed regular tetrahedron; the "other subgroup" (of order 2) is generated by the half-turn about the line joining the midpoints of two opposite edges of the cube. *H. On the structure of the quotient group of the unitary group with respect to its commutator subgroup.

Acta Math. Sinica **12** (1962), 352–368 (*Chinese*); *translated as Chinese Math.* **3** (1963), 382–398.

Let the [skew] field K have an involutary anti-automorphism, the action of which will be denoted by a bar. Let H be an n-by-n invertible hermitian [skew-hermitian] matrix over K. Such a matrix defines by $(x, y)=xH\bar{y}'$ a sesquilinear form on an n-dimensional vector space over K—with the vectors as row vectors, and with $'$ as transposition. Assume, furthermore, that this form is trace-valued and that H is not symmetric if char $K\neq 2$. Then the author establishes the following theorem: If $n=2\nu>2$, then the factor group $U_n(K, H)/TU_n(K, H)$ of the group of all H-unitary n-by-n matrices over K by the subgroup generated by all H-unitary transvections is isomorphic to the factor group K^*/SC, where K^* is the multiplicative group of K, S its subgroup of H-symmetric elements, and C its commutator subgroup. The number ν denotes the index of the sesquilinear form defined by H.

This result is contained in the more general Theorem 1 of G. E. Wall [Inst. Hautes Études Sci. Publ. Math. No. 1 (1959); MR **21** #3517], where a somewhat different description of the subgroup SC is given.

The Sylow 2-subgroups of the finite classical groups.

J. Algebra **1** (1964), 139–151.

The authors determine the Sylow 2-subgroups, and their normalizers, in the finite classical groups $\mathrm{GL}_n(q)$, $\mathrm{Sp}_{2n}(q)$, $\mathrm{U}_n(q)$, $\mathrm{O}_{2n+1}^{\pm}(q)$, $\mathrm{O}_{2n}(\pm 1, q)$, where q is an odd prime power. Let Z_k be the cyclic group of order k, T_m the wreath product $Z_2 \wr Z_2 \wr \cdots \wr Z_2$ (m terms). Let Q_n be a Sylow 2-subgroup of $\mathrm{GL}_n(q)$, $\mathrm{Sp}_n(q)$ or $\mathrm{U}_n(q)$, and let $n=2^{r_1}+\cdots+2^{r_t}$, where $r_1<r_2<\cdots<r_t$. Then $Q_n\cong Q_{2^{r_1}}\times\cdots\times Q_{2^{r_t}}$, $Q_{2^r}\cong Q_2 \wr T_{r-1}$. In the full linear and unitary cases, $N(Q_n)\cong Q_n\times Z_k\times\cdots\times Z_k$ (t Z_k's) for suitable k. In the symplectic case, $(N(Q_n):Q_n)=1$ or 3^t according as $q\equiv\pm 1$ or $\pm 3 \pmod 8$. The results for the orthogonal groups are similar. *G. E. Wall* (Sydney)

The flag-transitive collineation groups of the finite Desarguesian affine planes.

Canad. J. Math. **16** (1964), 443–472.

A collineation group of a plane is flag-transitive if it is transitive on incident point-line pairs, and the author solves completely the problem of determining the groups described in the title. Let π be a finite Desarguesian affine plane, let G be its full collineation group, and let E be the subgroup of G generated by the elations. If π is of order n, its points can be identified with the elements of a two-dimensional vector space over the field $\mathrm{GF}(n)$ of n elements, and hence with the elements of $\mathrm{GF}(n^2)$. The mappings $x\to ax^{p^b}+c$ (b an integer, $a\neq 0$, c in $\mathrm{GF}(n^2)$) of $\mathrm{GF}(n^2)$ into itself then form a subgroup U of G. The author's first main theorem is that, with a finite number of exceptions, a flag-transitive group of collineations either contains E or is contained in a conjugate under G of U. Moreover, the exceptions and the minimal flag-transitive subgroups of U are determined explicitly. Next, with one exception, again explicitly determined, flag-transitive subgroups of G are isomorphic only if they are conjugate.

The doubly-transitive collineation groups are, of course, flag-transitive, and the author goes on to determine which of his groups are doubly transitive. For these the isomorphism theorem takes a stronger form, for, again with one exception, non-isomorphic planes cannot have isomorphic doubly transitive collineation groups, and this remains true if one of them is non-Desarguesian. This enables the author to show that a finite non-Desarguesian plane cannot have a solvable doubly transitive collineation group, unless it is the near-field plane of order 9.

Berman, S. D.; Gudivok, P. M. 3550
Indecomposable representations of finite groups over the ring of p-adic integers. (Russian)
Izv. Akad. Nauk SSSR Ser. Mat. **28** (1964), 875–910.

Let ZG denote the group ring of a finite group G over the ring Z of rational integers. Consider representations of G by matrices with entries in Z, or equivalently, consider left ZG-modules having finite Z-bases. Although the present paper is couched in matrix terminology, for the purpose of this review we have rephrased its results in terms of the more natural module concepts. The main theorems in this paper have been independently obtained by Heller and the reviewer [Ann. of Math. (2) **76** (1962), 73–92; MR **25** #3993; ibid. (2) **77** (1963), 318–328; MR **26** #2520].

The problem of finding all ZG-modules, for a specific group G, was first attacked by Diederichsen [Abh. Math. Sem. Hansischen Univ. **13** (1940), 357–412; MR **2**, 4], using the ideas developed in a fundamental work of Zassenhaus [ibid. **12** (1938), 276–288]. Since every ZG-module is expressible as a direct sum of indecomposable modules, though not necessarily in a unique manner, the problem is at once reduced to determining a full set of indecomposable modules. Let $n(ZG)$ denote the number of modules in such a set.

For the case where G is cyclic of prime order, Diederichsen determined a full set of indecomposable ZG-modules. In addition, he gave an example to show that $n(ZG)$ is infinite for G cyclic of order 4. This example was fallacious, however, as was pointed out independently by Roiter [Vestnik Leningrad. Univ. **15** (1960), no. 19, 65–74; MR **23** #A1730] and Troy [Ph.D. Dissertation, Univ. Illinois, Urbana, Ill., 1961]. Both gave a full set of indecomposable ZG-modules for this case, in which $n(ZG)=9$.

This raised the question: For which groups G is the number $n(ZG)$ finite? It soon became evident that in order to answer this question, it was necessary to first solve the corresponding problem for p-adic integral representations, where p is prime. Let $Z_p{}^*$ denote the ring of all p-adic integers in the p-adic completion Q_p of the rational field Q.

For the moment, let H be any p-Sylow subgroup of G. By using a theorem of D. G. Higman [Duke Math. J. **21** (1954), 377–381; MR **16**, 794], together with the basic result that the Krull-Schmidt theorem holds for $Z_p{}^*G$-modules, it is trivial to show that $n(Z_p{}^*G)$ is finite if and only if $n(Z_p{}^*H)$ is finite. The problem is thereby reduced to the study of p-adic integral representations of p-groups, which explains the significance of the present work.

This paper gives a complete answer to the question: When is $n(Z_p{}^*G)$ finite? The same answer was independently given by Heller and the reviewer, and is as follows. Theorem: The number of indecomposable $Z_p{}^*G$-modules is finite if and only if the p-Sylow subgroups of G are cyclic, of order at most p^2.

By using this theorem, it is possible to decide for which groups the number $n(ZG)$ is finite. This was done by A. Jones [Michigan Math. J. **10** (1963), 257–261; MR **27** #3698], who proved that the number of indecomposable ZG-modules is finite if and only if for each prime p, the p-Sylow subgroups of G are cyclic of order at most p^2.

We turn now to a more detailed description of the present work. With each $Z_p{}^*G$-module M we may associate a Q_pG-module $Q_p\otimes M$ (tensor product over $Z_p{}^*$). Let us call the composition factors of $Q_p\otimes M$ the "Q_p-composition factors" of M; they are a collection of irreducible Q_pG-modules.

Suppose that G is cyclic of order p^m, with generator g, and for each n, $1\leq n\leq m$, let ε_n denote a primitive p^nth root of unity over Q_p. Form the Q_pG-module $K_n=Q_p(\varepsilon_n)$, on which g acts as multiplication by ε_n. Then $K_0, K_1, \cdots, K_m$ form a full set of irreducible Q_pG-modules. Set $J_n=Z_p{}^*[\varepsilon_n]$, a $Z_p{}^*G$-module in K_n.

Keeping the above notation, suppose that the $Z_p{}^*G$-module M has at most two types of Q_p-composition factors, say K_{n_1} and K_{n_2}, occurring with certain multiplicities. It is easily shown that M is an extension of a submodule M_1 by a factor module M_2, where for $i=1, 2$, M_i is a direct sum of copies of J_{n_i}. Since $\mathrm{Ext}^1_{Z_p{}^*G}(J_{n_2}, J_{n_1})$ can be computed explicitly, and turns out to be a local ring, the following theorem can be established. Let G be a cyclic p-group, and consider $Z_p{}^*G$-modules with at most two types of Q_p-composition factors. Then the number of such modules which are indecomposable is finite. Indeed, the only such indecomposables are J_{n_1}, J_{n_2}, and a finite set of non-split extensions of J_{n_1} by J_{n_2}.

The authors next construct various infinite families of indecomposable $Z_p{}^*G$-modules, for G cyclic of order p^m, $m\geq 3$. These modules, too complicated to list here, have three or more types of Q_p-composition factors, and depend on one or more matrix parameters. These matrix parameters have entries in some one of the rings J_n defined above. The existence of such families of modules implies that $n(Z_p{}^*G)$ is infinite for $m\geq 3$. Another consequence is that for $m\geq 5$, the problem of finding all indecomposable $Z_p{}^*G$-modules is at least as difficult as the classical unsolved problem of classifying pairs of matrices (over a field) under simultaneous similarity.

For H an abelian (p, p)-group, the authors give an infinite family of indecomposable $Z_p{}^*H$-modules. This easily implies that if G is any non-cyclic p-group, then $n(Z_p{}^*G)$ is infinite.

Several of the above constructions have been generalized by Dade [Ann. of Math. (2) **77** (1963), 406–412; MR **26** #2521] and Gudivok [Dokl. i Soobšč. Užgorodsk. Univ. Ser. Fiz.-Mat. Istor. Nauk **1962**, no. 5, 73; ibid. **1962**, no. 5, 81–82]. Let K be a finite extension of Q_p, let R be the valuation ring of K, and suppose that G is a p-group such that there exist at least 4 types of irreducible KG-modules. Dade and Gudivok both proved that under these assumptions, there exist infinitely many indecomposable RG-modules.

Turning next to the case where G is cyclic of order p^2, the authors of the present paper prove that $n(Z_p{}^*G)=4p+1$, and give a full set of indecomposable modules for this case. These coincide with those determined by Heller and the reviewer [loc. cit.]. The list originally given by the authors [Dokl. Akad. Nauk SSSR **145** (1962), 1199–1201; MR **25** #3095] is incorrect.

A somewhat more general theorem is established here, namely the following: *Let G be any cyclic p-group, and consider the set S of all $Z_p{}^*G$-modules having at most three types of Q_p-composition factors, one of which is the trivial Q_pG-module K_0. Let the other two types of Q_p-composition factors be K_r and K_s, where $0<r<s$. Then the number of indecomposable modules in the set S is precisely $5+4(p-1)p^{r-1}$.*

Gudivok, P. M. 3551

Representations of finite groups over certain local rings. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukrain. RSR **1964**, 173–176.

Let Z_p^* be the ring of p-adic integers, and Q_p its quotient field. Suppose that K is any finite extension field of Q_p with valuation ring R. For G a finite group, denote by $n(RG)$ the number of inequivalent indecomposable representations of G by matrices with entries in R. If H is any p-Sylow subgroup of G, a standard argument shows that $n(RG)$ is finite if and only if $n(RH)$ is finite. The author gives brief outlines of a number of interesting theorems about the finiteness of $n(RH)$. These generalize earlier results by various authors [Z. I. Borevič and D. K. Faddeev, Vestnik Leningrad. Univ. **14** (1959), no. 7, 72–87; MR **21** #4968; A. Heller and the reviewer, Ann. of Math. (2) **76** (1962), 73–92; MR **25** #3993; ibid. (2) **77** (1963), 318–328; MR **26** #2520; S. D. Berman and the author, #3550 above].

From these earlier results it follows that $n(RH)$ is infinite when H is non-cyclic. The present author proves that $n(RH)$ is infinite whenever H has at least four irreducible matrix representations over K. (This has also been shown by E. C. Dade [Ann. of Math. (2) **77** (1963), 406–412; MR **26** #2521].) This latter hypothesis is certainly fulfilled if H is cyclic of order p^m, $m \geq 3$, and also if H is cyclic of order at least 5, once we assume that R contains all pth roots of 1.

A rather surprising theorem is as follows: If R contains all p^2th roots of 1, and H is cyclic of order at least 3, then $n(RH)$ is infinite. This is the first example known in which there are only three irreducible K-representations of H and yet $n(RH)$ is infinite.

Another interesting result is the fact that $n(RH)$ is finite if H is cyclic of order p^2, where p is unramified in the extension K over Q_p.

Using a number of such results, the author obtains necessary and sufficient conditions for the finiteness of $n(RH)$, where K is a cyclotomic extension of R_p.

Isaacs, I. M.; Passman, D. S. 3552

Groups whose irreducible representations have degrees dividing p^e.

Illinois J. Math. **8** (1964), 446–457.

Let G be a finitely generated group and p a prime. Suppose that all irreducible representations of G over the complex numbers have degrees dividing p^e for a fixed exponent e. The authors' first main result is that G has a subinvariant series $G = A_e \supset A_{e-1} \supset \cdots \supset A_0$ such that A_0 is abelian, and A_i/A_{i-1} is an elementary abelian p-group with not more than $2i+1$ generators. In particular, G has an abelian subgroup A_0 whose index divides $p^{e(e+2)}$. The second main result is that a finitely generated group G all of whose irreducible complex representations have degree 1 or p, for a fixed prime p, is of one of the following types: (a) G is abelian; (b) G has a normal abelian subgroup of index p; or (c) G has a center Z with G/Z being a group of order p^3 and period p. Conversely, if G is a finite group of one of the above types, then its irreducible complex representations all have degree 1 or p. If G is finitely generated, of one of the above types, then G has a complete set of representations of degree 1 or p. Examples are given to show that all the types can occur. The first result is a sharpened version of Theorem III in an earlier paper of the authors [Canad. J. Math. **16** (1964), 299–309; MR **29** #4811]. For $p=2$ the second result reduces to a theorem of Amitsur [Illinois J. Math. **5** (1961), 198–205; MR **23** #A225]. The proofs are interesting but are too long to be described in this review.

Fuchs, L. 3554

On group homomorphic images of partially ordered semigroups.

Acta Sci. Math. (Szeged) **25** (1964), 139–142.

This paper is an investigation of those partially ordered semigroups which can be mapped order-homomorphically onto a partially ordered group. The result obtained is a generalization of a theorem of M.-L. Dubreil-Jacotin concerning lattice-ordered semigroups [C. R. Acad. Sci. Paris **232** (1951), 287–289; MR **12**, 473]. Let S be a partially ordered semigroup with identity element e, and let $a, b \in S$. The generalized right residual of a by b is $\langle a\cdot b\rangle = \{x \in S | xb \leq a\}$, and similarly $\langle a.\cdot b\rangle = \{x \in S | bx \leq a\}$. S is generalized residuated if for all $a, b \in S$, neither $\langle a\cdot b\rangle$ nor $\langle a.\cdot b\rangle$ is empty. If $U \subseteq S$, an element $u \in U$ is left multiplicatively maximal if $v \in S$ and $vu \in U$ imply $v \leq e$. An equivalence relation θ on S is a Dubreil-Jacotin congruence if (1) $a \equiv b$ (θ) implies $ca \equiv cb$ (θ) and $ac \equiv bc$ (θ), (2) $a \leq c \leq b$ and $a \equiv b$ (θ) imply $a \equiv c$ (θ), and (3) $a \equiv a'$ (θ), $e \equiv e'$ (θ) and $a' \leq e'$ imply $a \leq e$. The author proves the following theorem. Let S be a partially ordered semigroup with identity element e. Then these are equivalent. (A) θ is a Dubreil-Jacotin congruence on S and S/θ is a group. (B) (i) S is generalized residuated, (ii) $\langle e\cdot .a\rangle = \langle e.\cdot a\rangle$ for all $a \in S$, (iii) $\langle e\cdot .a\rangle$ contains a left multiplicatively maximal element for all $a \in S$, and (iv) $\langle e\cdot .a\rangle = \langle e\cdot .b\rangle$ if and only if $a \equiv b$ (θ).

Domoščnickaja, N. E. 3555

On the axiomatics of almost monotone ordered semigroups. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 804–814.

Let $(G, +, <)$ be an additively written semigroup with irreflexive order $<$. Let $<$ be linear and positive (i.e., $a+b>a, b$ for every $a, b \in G$; $<$ need not be compatible with $+$). The author shows that her previous conditions for the existence of a non-trivial isotone homomorphism of $(G, +, <)$ in the semigroup of all real numbers ordered in the natural way are equivalent to the following conditions. There exist e_1, e_2, e_3, e_4 such that, for every a, b, c, (1) $a<b$ implies $a+c<b+c+e_1$ and $c+a<$

e_1+c+b; (2) $a<b$ implies $na<nb+e_2$ for every integer n; (3) $n(a+b)<na+nb+e_3$ and $na+nb<n(a+b)+e_3$ for every integer n; (4) for every a there exists an integer n such that $ne_4>a$. It is shown that conditions (1)–(4) are independent. If $(G, +, <)$ satisfies (1)–(3), it is called an almost monotone ordered semigroup.

The relationship between the radical of a lattice-ordered group and complete distributivity.

Pacific J. Math. **14** (1964), 493–499.

In a lattice-ordered group G, denote by R_g, for each element $g\neq 0$ in G, the join of the lattice ideals of G not containing g, and let $R(G)$ be the intersection of the ideals R_g. $R(G)$ is the radical of G, and this paper begins a study of groups with $R(G)=0$. In particular, if G is representable, that is, is lattice-isomorphic to a subdirect sum of a cardinal sum of totally ordered groups, $R(G)=0$ if and only if G is completely distributive.

Graham Higman (Oxford)

Chehata, C. G. 3557

On a relation on ordered groups.

Proc. Math. Phys. Soc. U.A.R. (*Egypt*) No. 25 (1961), 79–82 (1964).

Let $[a, b]=a^{-1}b^{-1}ab$, $[a, b, c]=[[a, b], c]$, etc. An example is constructed to show that for elements a, b in an ordered group, the relation $[a, b^m, a, a]=e$ for some integer $m\neq 0, 1$ need not imply $[a, b, a, a]=e$. The example G is generated by elements $\cdots, a_{-2}, a_{-1}, a_0, a_1, a_2, \cdots$ and g, with the relations $g^{-1}a_mg=a_{m+1}$ for all m, $[a_m, a_n]=e$ for all m and all $n>m+1$, $[a_m, a_{m+1}, a_n]=e$ for all m and all $n\neq m$, and $[a_m, a_{m+1}, a_m, a_n]=e$ for all m and all n.

If C is the subgroup of G generated by the elements $c_m=[a_m, a_{m+1}, a_m]$ $(m=0, \pm 1, \pm 2, \cdots)$, B is the subgroup generated by the elements c_m and $b_m=[a_m, a_{m+1}]$ $(m=0, \pm 1, \pm 2, \cdots)$ and A is the subgroup generated by the elements a_m $(m=0, \pm 1, \pm 2, \cdots)$, the series $G\rhd A\rhd B\rhd C\rhd\{e\}$ has free Abelian factors. Suitably chosen orders on these factors can be combined to construct an order on G. In G, $[a_0, g^m, a_0, a_0]=e$ for all $m\neq 1$, but $[a_0, g, a_0, a_0]\neq e$.

J. C. Ault (Leicester)

Budach, L. 3558

Struktur Noetherscher kommutativer Halbgruppen.

Monatsb. Deutsch. Akad. Wiss. Berlin **6** (1964), 85–88.

Let S be a commutative semigroup. Consider the conditions: (i) the maximum condition for congruence relations in S; (ii) the existence of a finite system of generators for S. The fact that (ii) implies (i) was proved by L. Rédei [*Theorie der endlich erzeugbaren kommutativen Halbgruppen*, p. 153, Physica-Verlag, Würzburg, 1963; MR **28** #5130] and by the reviewer [Comment. Math. Univ. Carolinae **4** (1963), 87–92; MR **29** #4821]. The author proves that (i) implies (ii) and for the fact that (ii) implies (i) he indicates a simple proof. If S is regular and with identity element, then the maximum condition for ideals implies the existence of a finite subset F such that S is generated by $F\cup G$, where G is the group of all invertible elements.

{The reviewer feels the reader should know that the meanings of some basic symbols which the author does not explain can be found in the reviewer's paper [#3559 below].}

Drbohlav, Karel 3559

Zur Theorie der Kongruenzrelationen auf kommutativen Halbgruppen.

Math. Nachr. **26** (1963/64), 233–245.

Following the classical ideal theory of commutative rings, the ideal theory of semigroups has been studied by many people. In this paper the author treats it from the standpoint of congruence relations. Let S be a commutative semigroup, C a congruence relation on S, and $\mathfrak{C}(S)$ the set of all congruence relations on S. The universal relation on S is denoted by 1. For $C\in\mathfrak{C}(S)$ and $x\in S$, a congruence relation $C(x)$ is defined by $C(x)=\{(u, v)|xuCxv\}$, and the ideals $[C]^0$ and $[C]$ are associated with C as follows: $[C]^0=\{x\in S|C(x)=1\}$, $[C]=\{x\in S|x^\rho\in[C]^0$ for some positive integer $\rho\}$. C is called irreducible if $C=D\cap E$, $D\in\mathfrak{C}(S)$, $E\in\mathfrak{C}(S)$, $C\neq D$ imply $C=E$. C is prime if $x\in S$, $C\neq C(x)$ imply $x\in[C]^0$; C is primary if $x\in S$, $C\neq C(x)$ imply $x\in[C]$. S is supposed to satisfy the maximal condition for congruence relations, that is, any non-empty subset of $\mathfrak{C}(S)$ contains at least one maximal congruence relation. Then the following results are obtained. (I) Any irreducible congruence C is primary. (II) Any $C\in\mathfrak{C}(S)$ has at least one canonical factorization: $C=C_1\cap\cdots\cap C_r$, $C_i\in\mathfrak{C}(S)$, $i=1, \cdots, r$, where C_i is primary, $[C_i]\neq[C_j]$, $i\neq j$, and this factorization is irredundant. (III) The canonical factorization is unique in the following sense: if C has two canonical factorizations $C=C_1\cap\cdots\cap C_k\cap C_{k+1}\cap\cdots\cap C_r=D_1\cap\cdots\cap D_k\cap D_{k+1}\cap\cdots\cap D_s$, then $r=s$ and $[C_i]=[D_i]$, $i=1, \cdots, r$, for some permutation of indices; and furthermore, if $[C_i]\not\supset[C_j]$ $(i=1, \cdots, k$; $j=k+1, \cdots, r(=s))$, then $C_1\cap\cdots\cap C_k=D_1\cap\cdots\cap D_k$. The author introduces the concept of congruence ideals: an ideal A of S is a congruence ideal of S if there is a congruence relation C such that $[C]^0=A$. Under the maximal condition for congruence relations, the statements (I), (II) and (III) hold if the congruence relation C is replaced by the congruence ideal A ("irreducible", "primary" and "canonical factorization" are also defined on congruence ideals in parallel) and if the radical $[A]$ of A is defined by $[A]=\{x|x^\rho\in A$ for some $\rho\}$. Furthermore, the conditions for congruence ideals to be prime or primary are given.

T. Tamura (Davis, Calif.)

Petrich, Mario 3560

Sur certaines classes de demi-groupes. I, II.

Acad. Roy. Belg. Bull. Cl. Sci. (5) **49** (1963), 785–798; *ibid.* (5) **49** (1963), 888–900.

A complex [a non-empty subset] H of a semigroup D is strong ("fort") if xv, uv, $uy\in H$ imply $xy\in H$ for every $u, v, x, y\in D$, and is bilaterally strong if uxv, uyv, $wxz\in H$ imply $wyz\in H$. D is [bilaterally] rectangular if each one-element complex is [bilaterally] strong. If $e\in D$ is an idempotent, $G^{(e)}$ denotes the maximum subgroup of D containing e.

There are found several characterizations of idempotent rectangular semigroups (e.g., $Dx\cap xD=\{x\}$ for every $x\in D$). D is called inversed ("inversé") if for every $x\in D$ there exists x' such that xx' is an idempotent. D is an inversed [bilaterally] rectangular semigroup if and only if

$D^2 \cong E \times G$ [$D^3 \cong E \times G$], where E is a rectangular band, G is a group, and $xey = xy$ [$xeyez = xyz$] for every idempotent $e \in D$. Each subsemigroup of D is [bilaterally] strong if and only if $D^2 \cong E \times G$ [$D^3 \cong E \times G$], where E is a rectangular band, G is a periodic group (and all subgroups of G are invariant), $abc \in G^{(e)}$ implies $ac \in G^{(e)}$ [$axbyc \in G^{(e)}$ implies $abc \in G^{(e)}$] for every idempotent e. All complexes of D are [bilaterally] strong if and only if D satisfies one of the following conditions: (a) $xy = x^2$ for all x, y; (b) $xy = y^2$; (c) D^2 is the group of order 2 [(a) $axb = ayb$ for all $a, b, x, y \in D$; (b) D^3 is the group of order 2]. (The bilateral case is treated in the second part of the paper.)

The end of the paper is devoted to the modifications of the results mentioned for special kinds of semigroups (globally idempotent and idempotent groups).

Petrich, Mario 3561

On the structure of a class of commutative semigroups. (Russian summary)

Czechoslovak Math. J. **14** (89) (1964), 147–153.

Der Verfasser bezeichnet eine kommutative Halbgruppe S als N-Halbgruppe, wenn (1) $xz = yz \Rightarrow x = y$, (2) von je zwei Elementen aus S jedes eine Potenz des andern teilt und (3) S keine Idempotente enthält. Die Theorie der Zerlegungen der kommutativen Halbgruppen in archimedische, d.h. (2) genügende Unterhalbgruppen findet man in § 4.3 des Buches von Clifford und Preston [*The algebraic theory of semigroups*, Amer. Math. Soc., Providence, R.I., 1961; MR **24** #A2627]. Die Bedingung (1) kann man durch die Separabilität von S ersetzen, d.h. durch die Bedingung (4) $x^2 = y^2 = xy \Rightarrow x = y$. In einer endlich erzeugten N-Halbgruppe gibt es zu je zwei Elementen x und y zwei natürliche Zahlen p und q mit $x^p = y^q$.

Der Verfasser beweist, daß jede N-Halbgruppe mit zwei Erzeugenden a_1 und a_2 und natürlichen Zahlen m_1 und m_2, die bezüglich $a_2/a_1^{m_1}$ und $a_1/a_2^{m_2}$ minimal sind, zu folgender Halbgruppe S isomorph ist:

$$S = \{(k_1, k_2); k_1 = 0, 1, 2, \cdots; \quad k_2 = 0, 1, 2, \cdots, m_2 - 1 : k_1 + k_2 > 0\}$$

mit der Multiplikation

$$(k_1, k_2)(l_1, l_2) = (k_1 + l_1 + jm_1, k_2 + l_2 - jm_2),$$

wobei die ganze rationale Zahl j durch die Bedingung $0 \le k_2 + l_2 - jm_2 < m_2$ festgelegt ist. S kann man auch als diejenige Unterhalbgruppe der multiplikativen Gruppe der komplexen Zahlen beschreiben, die von $a_1 = 2^{1/m_1} e^{(2\pi i)/m_1}$ und $a_2 = 2^{1/m_2} e^{(4\pi i)/m_2}$ erzeugt wird.

Brown, Thomas C. 3562

On the finiteness of semigroups in which $x^r = x$.

Proc. Cambridge Philos. Soc. **60** (1964), 1028–1029.

Der Verfasser gibt einen neuen Beweis für den folgenden Satz von J. A. Green und D. Rees [dieselben Proc. **48** (1952), 35–40; MR **13**, 720] über die Äquivalenz der Vermutung von Burnside für Gruppen mit der für Halbgruppen: Für jede natürliche Zahl r, $r \ge 2$, ist die Endlichkeit aller endlich erzeugten und der Identität $x^r = x$ genügenden Halbgruppe S damit äquivalent, daß jede endlich erzeugte Gruppe von Exponenten $r - 1$ endlich ist. Der Beweis beruht auf dem Lemma, daß, falls die beiden Worte W und AXB in den Erzeugenden von S dasselbe Element von S repräsentieren, dies Element auch durch $W \cdot (XW)^{r-1}$ repräsentierbar ist. Daraus läßt sich nämlich schließen, daß für ein Element t von S, das durch ein alle Erzeugenden von S enthaltendes Wort repräsentierbar ist, die Unterhalbgruppe tSt von S eine Gruppe ist.

Ljapin, E. S. 3563

Conditions for complete embeddability in semigroups. (Russian)

Leningrad. Gos. Ped. Inst. Učen. Zap. **238** (1962), 3–20.

Several authors have considered embedding of semigroups as ideals (with various additional properties) in special semigroups; see, for example, Gluskin [Izv. Akad. Nauk SSSR Ser. Mat. **22** (1958), 439–488; MR **20** #2386; Mat. Sb. (N.S.) **47** (89) (1959), 111–130; MR **21** #4197; Dokl. Akad. Nauk SSSR **131** (1960), 1004–1006; MR **22** #6859] and the author [Mat. Sb. (N.S.) **52** (94) (1960), 589–596; MR **22** #12155; Leningrad. Gos. Ped. Inst. Učen. Zap. **103** (1955), 5–29]. In this paper an abstract version of these embedding theorems, and a number of sharpened results, are given.

Let A be a semigroup and $\varnothing \ne N \subset A$. If $a, a' \in A$ and $ax = a'x$ for $x \in N$, then a and a' are said to be equi-acting on N. Consider relations ρ between a semigroup B and a subsemigroup A of B such that if $A \subset B(\rho)$, then (1) A is a left ideal in B; (2) $\phi(A) \subset \phi(B)(\rho)$ for every homomorphism ϕ; (3) if $A \subset K \subset B$ and K is a subsemigroup, then $A \subset K(\rho)$. Particular such relations are the following: $A \subset B(\rho_0)$ if $A \subset B(\rho)$ and B contains no two elements equi-acting on A; $A \subset B(\rho_1)$ if $A \subset B(\rho)$ and every non-isomorphic homomorphism of B is non-isomorphic on A; $A \subset B(\rho_2)$ if $A \subset B(\rho)$ and for all subsemigroups B' such that $A \subset B'(\rho)$ and $B' \subset B$ ($B' \ne B$), there is a non-isomorphic homomorphism of B' that is an isomorphism on A. Connections among ρ_0, ρ_1, ρ_2 are explored, and a fourth relation ρ_3, too complicated to define here, is also introduced and studied. Sample theorems: $\rho_0 \subset \rho_1 \cup \rho_2$; if $A \subset B(\rho_0)$, then $A \subset B(\rho_1)$ if and only if B contains no two elements equi-acting on A.

Makkai, M. 3564

Solution of a problem of G. Grätzer concerning endomorphism semigroups.

Acta Math. Acad. Sci. Hungar. **15** (1964), 297–307.

Let $\mathfrak{A}$ be a universal algebra, i.e., a non-empty set with a finite or infinite system of finitary operations on this set. $\mathfrak{E}(\mathfrak{A})$, $\mathfrak{M}(\mathfrak{A})$, $\mathfrak{H}(\mathfrak{A})$, denote, respectively, the semigroups of all endomorphisms, all monomorphisms (i.e., one-to-one endomorphisms) and all epimorphisms (i.e., endomorphisms onto) of $\mathfrak{A}$ under the usual operation of superposition. G. Grätzer ["Some Results on Universal Algebras", Mimeographed Notes, Budapest, 1962] proposed to find under what conditions a given triplet (E, M, H) of semigroups is isomorphic to some triplet $(\mathfrak{E}(\mathfrak{A}), \mathfrak{M}(\mathfrak{A}), \mathfrak{H}(\mathfrak{A}))$. He has found three necessary conditions: (C1) E has a unit element 1; (C2) M is a subsemigroup of E, all elements of M are right regular (i.e., right cancellative) in

E, $E-M$ is a right ideal of E and $1 \in M$; (C3) H satisfies the dual conditions: H is a subsemigroup of E, all elements of H are left regular in E, $E-H$ is a left ideal of E and $1 \in H$. E. Fried and the author have found the further necessary condition: (C4) If $m \in M$, $h \in H$, $x \in E$, $y \in E$ and $xm = hy$, then there exists $z \in E$ such that $x = hz$.

The author proves that conditions (C1)–(C4) are both necessary and sufficient. (C1) and (C2) form an abstract characterization of $(\mathfrak{E}(\mathfrak{A}), \mathfrak{M}(\mathfrak{A}))$, (C1) and (C3) form a characterization of $(\mathfrak{E}(\mathfrak{A}), \mathfrak{H}(\mathfrak{A}))$. It is noteworthy that for (E, M, H) satisfying (C1)–(C4), there exists $\mathfrak{A}$ with one-place operations only.

{Remark of the reviewer: Lemma 1, which is used for the proof of sufficiency, is very similar to the results of È. G. Šutov [Učen. Zap. Udmurtsk. Ped. Inst. Vyp. 12 (1958), 24–36].} *B. M. Schein* (*Šain*) (Saratov)

Lallement, Gérard 3565

Décompositions matricielles et homomorphismes d'un demi-groupe.

C. R. Acad. Sci. Paris **259** (1964), 273–276.

In this paper the author discusses the homomorphisms of arbitrary semigroups onto completely 0-simple semigroups by using the concept of matricial congruences.

A rectangular 0-band is a semigroup B with 0 such that, for any $a, b \in B$, $aba = a$ or 0, and for any $a, b \in B$, $a \neq 0$ and $b \neq 0$, there is $x \in B$ such that $axb \neq 0$. If a semigroup D has as an image a rectangular 0-band B, the congruence class W corresponding to the zero of B is a two-sided primary ideal of D. A primary ideal W of D is an ideal of D which satisfies: $aDb \subseteq W$ implies $a \in W$ or $b \in W$. A congruence $\mathfrak{M}$ on D, as well as the corresponding decomposition, is called W-matricial if (1.1) W is a class modulo $\mathfrak{M}$, (1.2) $aba \notin W$ implies $aba \equiv a \bmod \mathfrak{M}$. A semigroup D admits a W-matricial decomposition if and only if the primary ideal W satisfies: (2) $abc \in W$ implies $ab \in W$ or $bc \in W$. An equivalence $\mathscr{R}$ is called left [right] W-zero if it is left [right] compatible, if W is a class modulo $\mathscr{R}$, and if $x, y \in D$ and $xy \notin W$ imply $xy \equiv x$ [$xy \equiv y$] mod $\mathscr{R}$. Then a relation is a W-matricial congruence if and only if it is the intersection of a left W-zero equivalence and a right W-zero equivalence. (This expression of intersection is unique.) Consider a strong, regular family of weakly unitary subsemigroups [see the author, same C. R. **258** (1964), 3609–3612; MR **28** #4046]. Their union K satisfies: (3.1) it is reflexive ($ab \in K$ implies $ba \in K$) and its residue W is a primary ideal satisfying (2); (3.2) there exist a left W-zero equivalence $\mathscr{R}$, whose classes are R_i ($i \in I$) and W, and a right W-zero equivalence $\mathscr{L}$, whose classes are L_λ ($\lambda \in \Lambda$) and W, such that for $i \in I$, $K \cap R_i$ is a right unitary subsemigroup and for $\lambda \in \Lambda$, $K \cap L_\lambda$ is a left unitary subsemigroup [see Dubreil, *Algèbre*, Tome I, deuxième édition, Gauthier-Villars, Paris, 1954; MR **16**, 328]. Conversely, every complex K satisfying (3.1) and (3.2) is a union of subsemigroups satisfying (2). A W-matricial congruence $\mathfrak{M} = \mathscr{R} \cap \mathscr{L}$ satisfying (3.2) relative to a complex K which satisfies (3.1) is called "connected to K", similarly for the matrix of $D/\mathfrak{M}$. The homomorphisms of a semigroup onto a completely 0-simple semigroup are associated with the pairs formed by a complex K and a matrix connected with K contracted from that of $D/B(W)$, where $B(W)$ is the intersection of the smallest left W-zero equivalence and the smallest right W-zero equivalence. *T. Lajos, Sándor 3566

A criterion for Neumann regularity of normal semigroups.

Acta Sci. Math. (*Szeged*) **25** (1964), 172–173.

A semigroup S is said to be Neumann regular in case x belongs to xSx for every x in S; it is said to be normal in case $xS = Sx$ for every x in S. The author proves that a normal semigroup is regular if and only if every left ideal of it is idempotent. *D. J. Foulis* (Gainesville, Fla.)

Aizenštat, A. Ja. 3567

On homomorphisms of semigroups of endomorphisms of ordered sets. (Russian)

Leningrad. Gos. Ped. Inst. Učen. Zap. **238** (1962), 38–48.

Let Ω be an ordered (= partially ordered) set. The set Σ of all endomorphisms (i.e., isotonic transformations) of Ω is a semigroup under the natural multiplication of transformations.

It is well known that if S is a semigroup, then each of its ideals generates some congruence. If all congruences of S are generated by ideals, then S is called semi-simple. This term is due to E. S. Ljapin [Izv. Akad. Nauk SSSR Ser. Mat. **14** (1950), 367–380; MR **12**, 154]. The author shows that Ω is a finite linearly ordered set if and only if Σ is semi-simple. She also finds all ideals of Σ in this case: each of the ideals has the form $I_k = \{S \in \Sigma : S\Omega$ contains k elements at most$\}$. There exist semi-simple semigroups that are not isomorphic to the semigroups of all endomorphisms of finite linearly ordered sets.

Hoehnke, Hans-Jürgen 3568

Zur Theorie der Gruppoide. VII.

Math. Nachr. **27** (1963/64), 289–298.

This paper is the continuation of the author's earlier paper [same Nachr. **25** (1963), 191–198; MR **27** #3735]. Let Γ be the direct product of a group G and a Brandt groupoid S_I, where $S_I = \{e_{ik} | i, k \in I\}$, and Λ is a subgroupoid of Γ. Further, Δ denotes an Ehresmann subgroupoid of Λ, and $\mathfrak{T}(\Gamma)$ the Loewy group [cf. the author's earlier paper, loc. cit.]. Assume that Δ satisfies the following condition: For $t \in \mathfrak{T}(\Gamma)$ with $t\Delta t^{-1} \subseteq \Lambda$, there is $s \in R(\Lambda)$ such that $s^{-1}\Delta^{(\mu)}s = t\Delta^{(\mu)}t^{-1}$, $\Delta = \bigcup_{\mu \in M} \Delta^{(\mu)}$, $\Delta^{(\mu)} \cap \Delta^{(\nu)} = \varnothing$, $\mu \neq \nu$. The main theorem of this paper gives the number of distinct conjugate subgroupoids of Λ with respect to $\mathfrak{T}(\Gamma)$, that is, $\Delta \subseteq \Lambda \cap (t^{-1}\Lambda t)$, under the above assumption on Δ.

Cardoso, Jayme Machado 3569

Subtractive quasi-groups. (Portuguese)

Gaz. Mat. (*Lisboa*) **24** (1963), 7–10.

A multiplicative groupoid G is a quasi-group when $ax = b$ and $ya = b$ always has unique solutions. A subtractive groupoid (s.g.) has right unit and inverses with respect to it; in addition, it satisfies the special associative commutative laws $(ab)c = (ac)b$, $a(bc) = c(ba)$. The author proves various properties of such systems; among the principal results are: An s.g. is a quasi-group; it is commutative if and only if its identity is bilateral; for finite s.g. the theorem of Lagrange about the expansion in co-sets holds. *O. A theorem on cardinal numbers associated with a locally compact Abelian group.

Proc. Cambridge Philos. Soc. **60** (1964), 701–704.

The following conjecture was announced by E. Hewitt in his paper [Fund. Math. **53** (1963), 55–64; MR **27** #4889]. Let G be an abelian group and let τ_1 and τ_2 be two Hausdorff locally compact topologies on G so that G becomes a topological group in the topology τ_1 as well as in τ_2. Let τ_1 be strictly stronger than τ_2. (That is, there are more open sets in τ_1 than in τ_2.) Then there are at least 2^c continuous characters of G in the topology τ_1 which are discontinuous in the topology τ_2.

In this paper this conjecture is proved. The line of argument runs as indicated in a previous review of the reviewer [see MR **27** #4889]. {Reviewer's remark: The reviewer also obtained this result independently (to appear in Math. Z.). K. Ross also solved this problem independently (unpublished). The method is the same in all three cases.} *M. Rajagopalan* (Urbana, Ill.)

Freudenthal, H. 3571

Ein Zerlegungssatz für im Kleinen kompakte Gruppen.

Arch. Math. **15** (1964), 161–165.

Let G be a locally compact group, and A a connected abelian subgroup such that the left coset space G/A is compact. Then there is a normal vector subgroup N and a compact subgroup C in G such that G splits as a semidirect product of N and C. This was first proved by Hofmann and Mostert [Mem. Amer. Math. Soc. No. 43 (1963); MR **27** #1529]. Another proof was recently given by J. Tits [Topology **3** (1964), suppl. 1, 97–107; MR **28** #2170]; the statement of this result was incorrectly formulated in MR **28** #2170. The author gives another proof after proving the following Theorem II. Let G be a topological group whose identity component is a Lie group with Lie algebra $\mathfrak{G}$. Define $\mathfrak{F}=\{X\in\mathfrak{G}: X^G$ is bounded$\}$. Then $\mathfrak{F}$ is a Lie sub-algebra of $\mathfrak{G}$, and if F is the corresponding Lie subgroup of G, then F is a connected and maximally almost periodic normal subgroup of G. This gives a much simpler and more elegant proof than the original. (Tits's approach is different from either and proves more.) Another consequence of Theorem II is Theorem III: If G is a simple Lie group with a relatively compact set b^G of conjugates for some $b\in G$, then G is itself compact. His Theorem IV is the same as Theorem X of Hofmann and Mostert [loc. cit.].

Über die schwache Konvergenz der Haarschen Masse von Untergruppen.

Math. Ann. **156** (1964), 1–8.

Theorem 1: If $\{\mu_i\}$ is a set of (suitably normed) Haar measures of closed subgroups X_i of a Hausdorff locally compact group, then weak convergence of the μ_i is equivalent to Hausdorff convergence of the X_i. Theorem 2: The set of Haar measures of all closed subgroups, together with the zero measure, is compact.

J. G. Wendel (Ann Arbor, Mich.)

Gerstenhaber, Murray; Rothaus, Oscar S. 3573

The solution of sets of equations in groups.

Proc. Nat. Acad. Sci. U.S.A. **48** (1962), 1531–1533.

Let H be a compact connected Lie group of rank m, $W_1,\cdots,W_r$ words in elements of H ("constants") and indeterminates $x_1,\cdots,x_r$ and d_{ij} the exponent sum of x_j in W_i. Put $d=\det(d_{ij})$; then the degree of the mapping $T: H^{(r)}\to H^{(r)}$ given by $(x_1,\cdots,x_r)\mapsto(W_1,\cdots,W_r)$ is d^m, and if $d\neq 0$, then there are values of $x_1,\cdots,x_r$ in H such that for these values of x_i, $W_j=1$ for $j=1,\cdots,r$. This generalization of Hopf's mapping theorem [H. Hopf, Comment. Math. Helv. **13** (1940), 119–143; MR **2**, 35], whose proof relies on Hopf's original theorem, leads to two further results: If G is a finite group, W_i $(i=1,\cdots,r)$ words in $x_1,\cdots,x_r$ with coefficients in G, then the simultaneous equations $W_i=1$ have a solution in a finite supergroup of G provided $d\neq 1$. This generalizes significantly existing results by F. Levin [Bull. Amer. Math. Soc. **68** (1962), 603–604; MR **26** #212] and H. Schiek [Math. Ann. **146** (1962), 314–320; MR **25** #111]. The other result is a generalization of the "Freiheitssatz" [W. Magnus, J. Reine Angew. Math. **170** (1934), 235–240].

Matsumoto, Hideya 3574

Quelques remarques sur les groupes algébriques réels.

Proc. Japan Acad. **40** (1964), 4–7.

The author announces without proof two propositions and four theorems related to work of previous authors, including Kostant, Murakami, Satake, Sugiura and Tits. His results are concerned with (i) the connectivity of algebraic groups, and (ii) the automorphisms and conjugate classes of Cartan and maximal solvable sub-algebras of semi-simple Lie algebras.

A. J. Coleman (Kingston, Ont.)

Kopfermann, Klaus 3575

Maximale Untergruppen Abelscher komplexer Liescher Gruppen.

Schr. Math. Inst. Univ. Münster No. 29 (1964), iii + 72 *pp*.

Let G be a complex Lie group. A closed complex normal subgroup N of G is called holomorphically [meromorphically] maximal in G if (1) every holomorphic [meromorphic] function on N is a constant and (2) G/N is holomorphically [meromorphically] separable. A complex manifold M is called holomorphically [meromorphically] separable if for $x,y\in M$, $x\neq y$, there is a holomorphic [meromorphic] function f on M such that (f is holomorphic at x, y and) $f(x)\neq f(y)$. If G is holomorphically maximal in G itself (e.g., a complex torus), G is called a toroidal group. The author considers the generalization of the theory of abelian functions (i.e., meromorphic functions on a complex torus) to meromorphic functions on a toroidal group.

In Chapter 1, the author proves that every connected complex abelian Lie group is the direct product of a toroidal group with $\mathbf{C}^m\times\mathbf{C}^{*n}$, and he characterizes a complex abelian Lie group to be toroidal. In Chapter 2,

the author proves that for any meromorphic function f on a toroidal group $G=\mathbf{C}^m/D$ (D is a discrete subgroup of $\mathbf{C}^m$) there exist theta functions g, h with respect to D such that $f\circ p=g/h$, where $p:\mathbf{C}^m\to G$ is the projection and where a holomorphic function g on C^m is called a theta function with respect to D if for each $c\in D$ there exists a linear polynomial L_c such that $g(z+c)=g(z)\exp(L_c(z))$ for $z\in\mathbf{C}^m$. Then, the notion of a reduced [respectively, trivial] theta function is introduced and the author proves that every theta function can be written as the product of a reduced theta function with a trivial one. The notion of a (non-degenerate) Riemann form with respect to D is also defined.

In Chapter 3, the author considers the complex torus and proves the classical theorem which asserts the equivalence of the following four conditions for a complex torus $G=\mathbf{C}^m/D$: (1) there exists a non-degenerate meromorphic function f on $\mathbf{C}^m/D$, i.e., the period group of $f\circ p$ is discrete in $\mathbf{C}^m$; (2) there exists a non-degenerate Riemann form with respect to D; (3) G is a projective-algebraic manifold; (4) the transcendence degree of the meromorphic function field of G over the complex number field (which is called the algebraic dimension of G) is m. The following theorems are also proved. If G is of algebraic dimension t, then G contains the meromorphically maximal subgroup N in G with $\dim N=\dim G-t$. For any $m>1$ and $0\leq t\leq m$ (m, t being integers), there exists an m-dimensional complex torus G of algebraic dimension t.

In Chapter 4, using the results in the preceding chapters, the author proves the existence of the meromorphically maximal subgroup in every connected complex abelian Lie group, and shows an example of a non-compact complex Lie group without non-constant meromorphic functions. *Akihiko Morimoto* (La Jolla, Calif.)

Bernat, Pierre 3576

Sur le dual d'un groupe résoluble exponentiel.

C. R. Acad. Sci. Paris **258** (1964), 5311–5314.

Let $\mathfrak{g}$ be a real solvable Lie algebra which is exponential, that is, such that the exponential mapping exp of $\mathfrak{g}$ into the corresponding simply connected Lie group G is surjective. Let f be a linear form on $\mathfrak{g}$ and $S(f)$ be the set of subalgebras $\mathfrak{h}$ of $\mathfrak{g}$ such that $f|[\mathfrak{h},\mathfrak{h}]=0$. Then any $\mathfrak{h}$ in $S(f)$ defines a character of the subgroup $\exp\mathfrak{h}$ which induces a unitary representation $\rho(f,\mathfrak{h})$ of G. The author gives the conditions for $\rho(f,\mathfrak{h})$ to be irreducible. Let $E(f)$ denote the set of $\mathfrak{h}$ in $S(f)$ with the following property: For any couple $(\mathfrak{k},\mathfrak{p})$ of a subalgebra $\mathfrak{k}$ of $\mathfrak{g}$ and of an ideal $\mathfrak{p}$ of $\mathfrak{k}$, if $\mathfrak{k}\supset\mathfrak{h}$ and if $f|\mathfrak{p}=0$, then $\mathfrak{h}$ contains the inverse image of the ideal sum of (non-zero) minimal ideals of $\mathfrak{k}/\mathfrak{p}$ under the canonical mapping $\mathfrak{k}\to\mathfrak{k}/\mathfrak{p}$. If any element of $S(f)$ of maximal dimension belongs to $E(f)$, or if G is quasi-nilpotent, that is, $\mathfrak{g}$ is solvable exponential and for any x in $\mathfrak{g}$ the real proper values of ad x are all zero, then the set of elements $\mathfrak{h}$ of $S(f)$ such that $\rho(f,\mathfrak{h})$ is irreducible coincides with the set of elements $\mathfrak{h}$ of $S(f)$ of maximal dimension. *S. Tôgô* (Hiroshima)

Saito, Masahiko 3577

Représentations unitaires du groupe des déplacements du plan $\mathfrak{p}$-adique.

Proc. Japan Acad. **39** (1963), 407–409.

From the introduction: "Le but de cette note est une extension au cas $\mathfrak{p}$-adique des résultats de Vilenkin [Uspehi Mat. Nauk. **11** (1956), no. 3 (69), 69–112; MR **19**, 153] sur les représentations du groupe des déplacements euclidiens. En calculant explicitement les coefficients matriciels des représentations unitaires irréductibles à l'aide d'une base naturelle, on est conduit à une certaine classe de fonctions que l'on pourrait appeler fonctions de Bessel $\mathfrak{p}$-adiques. En particulier les fonctions sphériques zonales s'expriment par les fonctions de Bessel $\mathfrak{p}$-adiques d'indice 0, qui essentiellement n'est autre qu'une somme de Gauss du corps des restes." *R. Steinberg* (Los Angeles, Calif.)

Boseck, Helmut 3578

Darstellungen von Matrixgruppen über topologischen Körpern. I.

Math. Nachr. **24** (1962), 229–243.

Let G be the group PGL(2, K), where K is a discrete-valued locally compact field. G acts on K as a group of fractional linear transformations, that is, if $\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix}$ is a matrix representing $g\in G$, then $xg=(\alpha x+\beta)/(\gamma x+\delta)$. For $x\in K$ and $g\in G$ set $\beta(x,g)=|\det g|\,|\beta x+\delta|^{-2}$, where $x\to|x|$ is the normalized valuation on K. For each character χ of the multiplicative group K^* of K and $g\in G$ define a unitary operator on $L^2(K)$ (formed with respect to Haar measure on the additive group K^+ of K) by: $T_g^{(\chi)}f(x)=\chi((\det g)(\beta x+\delta)^{-2})\beta^{1/2}(x,g)f(xg)$. The maps $g\to T_g^{(\chi)}$ are unitary representations of G which the author shows, by means of the Fourier transform on K^+, are irreducible, and comprise what the author calls the first principal series of representation of G. He obtains these representations as the components in a direct integral decomposition of a quasi-regular representation of G defined as follows. Let p be a prime in K and put $Z=K(\pi)$, where $\pi^2=p$. For $z=x+\pi y\in Z$ put $Nz=x^2-py^2$ and let $Z_0=\{z=x+\pi y: y\neq 0\}$. G acts transitively as a group of fractional linear transformations on Z_0. Choose $x\in K$ and $s\in K^*$. The author calls the set

$$\omega(x,s)=\{z\in Z_0: N(z-(x+\pi s))=-ps^2\}$$

a horosphere. Let Ω_0 be the set of horospheres in Z_0. G acts transitively on Ω_0 and there is a quasi-invariant measure in Ω_0 which means that G acting on Ω_0 defines a unitary representation T on $L^2(\Omega_0)$. By use of the Fourier transform on K^* the author shows that T is the direct integral of the $T^{(\chi)}$. Similar results are given for the group PSL(2, K). *A. Kleppner* (College Park, Md.)

Nakamura, Masahiro; Umegaki, Hisaharu 3579

Heisenberg's commutation relation and the Plancherel theorem.

Proc. Japan Acad. **37** (1961), 239–242.

Let G and X be a Pontrjagin pair of locally compact abelian groups. For a Borel set $S\subset G$ let $E(S):L^2(G)\to L^2(G)$ be the operator or multiplication with the characteristic function of S. Let $U(g)$ be the left regular representation of G, and let $V(\chi)=\int\overline{(g,\chi)}\,dE(g)$. Similarly, let $E'(S')$ be the corresponding multiplication operator on X, let $V'(\chi)$ be the left regular representation of X on $L^2(X)$, and let $U'(g)=\int(g,\chi)\,dE'(\chi)$. Then both the pairs (U,V) and (U',V') satisfy the Heisenberg commutation relation $U(g)V(\chi)=(g,\chi)V(\chi)U(g)$. By the Mackey-Loomis theorem

there is a unitary transformation $T: L^2(G)\to L^2(X)$ such that $U'T=TU$ and $V'T=TV$. The Plancherel theorem is deduced from this by showing that T is essentially the Fourier transformation F when restricted to $L^1(G)\cap L^2(G)$. This is done as follows: The Heisenberg relation implies $T(\varphi*\psi)=T(\varphi)F(\psi)$. Let φ run through an approximate identity. One shows that $T\varphi$ tends to a nonzero constant. *J. Wang* (New Haven, Conn.)

Helgason, Sigurdur 3581

Invariants and fundamental functions.

Acta Math. **109** (1963), 241–258.

Let V be a finite-dimensional vector space over $\mathbf{R}$. Each $X\in V$ gives rise to a differential operator $\partial(X)$ on V. Let G be a subgroup of $\mathrm{GL}(V)$. Let $I(V)$ denote the set of G-invariants in the symmetric algebra $S(V)$, and let $I_+(V)$ denote the set of G-invariants without constant term. The group G acts on the dual space V^* as $(gv^*)(v)=v^*(g^{-1}v)$, and we have $I_+(V^*)\subset I(V^*)\subset S(V^*)$. An element $p\in S^c(V^*)=\mathbf{C}\otimes S(V^*)$ is called G-harmonic if $\partial(J)p=0$ for all $J\in I_+(V)$. Let $H^c(V^*)$ denote the set of G-harmonic polynomial functions. Let N_G denote the variety in V^c defined by

$$N_G=\{X\in E^c\,|\,j(X)=0 \text{ for all } j\in I_+(V^*)\}.$$

Now suppose B_0 is a nondegenerate symmetric bilinear form on $V\times V$; let B denote the unique extension of B_0 to a bilinear form on $V^c\times V^c$. If $X\in V^c$, let X^* denote the linear form $Y\to B(X,Y)$ on V^c. Let $H_1(V^*)$ denote the vector space over $\mathbf{C}$ spanned by the functions $(X^*)^n$ ($n=0,1,2,\cdots;X\in N_G$), and let $H_2(V^*)$ denote the set of G-harmonic polynomial functions which vanish identically on N_G. Then the main result of § 1 can be stated as the following theorem. Suppose that G leaves B_0 invariant and suppose that either (1) G is compact and B_0 is positive definite, or (2) G is connected and semisimple. Then (*) $S(V^*)=I(V^*)H(V^*)$ and $H^c(V^*)=H_1(V^*)+H_2(V^*)$ (direct sum). (*) was also obtained independently by B. Kostant [Amer. J. Math. **85** (1963), 327–404; MR **28** #1252].

In § 2, a result similar to (*) is obtained for the exterior algebra $\Lambda(V^*)$. In § 3, the quadric $C_{p,q}\subset\mathbf{R}^{p+q+1}$ given by the equation

$$Q(X)=x_1^2+\cdots+x_p^2-x_{p+1}^2-\cdots-x_{p+q+1}^2=-1 \qquad (p\geq 0,\ q\geq 0)$$

is considered. Let $O(p,q+1)$ be the group of linear transformations of $\mathbf{R}^{p+q+1}$ leaving Q invariant. The complex-valued continuous function f on $C_{p,q}$ is called fundamental if the vector space V_f over $\mathbf{C}$ spanned by the translations of f by the group $O(p,q+1)$ is finite-dimensional. Then the second main result of this paper can be stated as the following theorem. Let f be a fundamental function on $C_{p,q}$. Assume $(p,q)\neq(1,0)$. Then there exists a polynomial $P=P(x_1,\cdots,x_{p+q+1})$ such that $f=P$ on $C_{p,q}$. *M. Sugiura* (Osaka)

Mautner, F. I. 3582

Spherical functions over $\mathfrak{P}$-adic fields. II.

Amer. J. Math. **86** (1964), 171–200.

Pour I voir le même J. **80** (1958), 441–457 [MR **20** #82]. Soient $G=\mathrm{PGL}(2,\Omega)$ le groupe projectif sur un corps $\mathfrak{P}$-adique Ω; K son sous-groupe compact maximal formé des éléments provenant de matrices à coefficients dans l'anneau des entiers $\mathfrak{O}$ de Ω. Etant donnée une représentation unitaire irréductible $\mathfrak{u}$ de K, l'auteur considère l'ensemble $S_{\mathfrak{u}}{}^0$ des fonctions $\mathfrak{f}(g)$ sur G, dont les valeurs sont des transformations linéaires de l'espace de la représentation $\mathfrak{u}$, $\mathfrak{f}$ étant supposée continue à support compact et vérifiant la relation

$$\mathfrak{f}(kgk')=\mathfrak{u}(k)\mathfrak{f}(g)\mathfrak{u}(k')$$

pour $g\in G$, k, k' dans K; ces fonctions forment une algèbre pour la convolution. Si $\mathfrak{f}=(f_{ij})$, matrice par rapport à une base orthonormale de l'espace de $\mathfrak{u}$ (supposé de dimension r), l'application $\mathfrak{f}\to r\cdot f_{11}$ est un isomorphisme de $S_{\mathfrak{u}}{}^0$ sur l'algèbre $S_e{}^0$ des fonctions continues à support compact f sur G telles que $f(g)=\int_K e(k)f(k^{-1}g)\,dk$, où $e=r\cdot u_{11}$. L'auteur se borne à un type de représentation $\mathfrak{u}=\mathfrak{u}_\chi$, obtenu à partir d'un caractère χ de $\bar{A}$, groupe multiplicatif de $\mathfrak{O}/\mathfrak{P}^m$ pour un entier $m\geq 1$ fixé; $\bar{A}$ est un tore maximal du groupe $\bar{K}=\mathrm{PGL}(2,\mathfrak{O}/\mathfrak{P}^m)$, image canonique de K, et on a donc une représentation $\bar{\mathfrak{u}}$ de $\bar{K}$ induite par χ; $\mathfrak{u}$ est la composée de $\bar{\mathfrak{u}}$ et de l'homomorphisme canonique $K\to\bar{K}$. On considère d'autre part la "série principale" de représentations $g\to M(g,\alpha)$ de G obtenues comme représentations induites par des caractères α du tore maximal A de G (isomorphe à Ω^*); en fait, l'auteur se borne aux caractères α tels que $\alpha(\tau^n\eta)=q^{n(s-1)}\alpha_1(\eta)$ (τ uniformisante de $\mathfrak{O}$, q nombre d'éléments du corps résiduel $\mathfrak{O}/\mathfrak{P}$, η variant dans le groupe des unités $\mathfrak{U}$ de $\mathfrak{O}$, s nombre complexe), où α_1 est un caractère fixé de $\mathfrak{U}$, non réel et égal à 1 dans $1+\mathfrak{P}^m$ (même entier m que ci-dessus). Il calcule explicitement la représentation $M(g,\alpha)$ correspondante, et montre qu'elle est irréductible, et qu'elle est unitaire si et seulement si $s=\frac{1}{2}+it$ (t réel). On considère alors, pour $f\in S_e{}^0$, sa "transformée de Fourier" $\mathfrak{F}(\alpha)=\int f(g)M(g,\alpha)^*\,dg$; on montre que c'est une matrice scalaire dont on calcule explicitement la valeur $F(\frac{1}{2}+it)$ des éléments diagonaux. Si $S_e{}^2$ est l'adhérence de $S_e{}^0$ dans $L^2(G)$, on note $\mathfrak{S}_e{}^2$ le sous-espace orthogonal au noyau de l'application $f\to F(\frac{1}{2}+it)$, et on prouve (grâce à l'expression explicite de $F(\frac{1}{2}+it)$) que la restriction de $f\to F(\frac{1}{2}+it)$ à $\mathfrak{S}_e{}^2$ est un isomorphisme sur l'espace L^2 pour la mesure $c\cdot dt$, avec $c=(q^m+q^{m-1})\log q/2\pi$ sur l'intervalle $0\leq t\leq 2\pi/\log q$; on a en outre la formule d'inversion

$$f(g)=c\cdot\int_0^{2\pi/\log q}F(\tfrac{1}{2}+it)M_{11}(g,\tfrac{1}{2}+it)\,dt.$$

On peut d'ailleurs préciser encore l'intersection $\mathfrak{S}_e{}^0=\mathfrak{S}_e{}^2\cap S_e{}^0$, qui est une sous-algèbre de $S_e{}^0$, isomorphe à l'algèbre des polynômes trigonométriques $\sum_n a_n q^{nit}$; en outre, si $q>2$ et $m>1$, on montre que $\mathfrak{S}_e{}^0\neq S_e{}^0$.

Egardt, L. 3584

On the construction of invariants for SU(n).

Ark. Fys. **27** (1964), 193–194.

Let $X_1, \cdots, X_{n^2-1}$ denote a basis for the Lie algebra of SU(n), with $[X_i, X_j] = c_{ijk}X_k$ and $\frac{1}{2}\{X_i, X_j\} = \delta_{ij}I/n + d_{ijk}X_k$. Then

$$c_{ijk} = \mathrm{Tr}(X_i[X_j, X_k])$$

and

$$d_{ijk} = \mathrm{Tr}(\tfrac{1}{2}\{X_i, X_j\}X_k).$$

The author first notes that the c's and d's are related by the equation $d_{jkl}c_{ilm} + d_{kil}c_{jlm} + d_{ijl}c_{klm} = 0$. He then employs this relation to show that if Y_i and Z_i are elements of the Lie algebra chosen so that $[X_i, Y_j] = c_{ijk}Y_k$ and $[X_i, Z_j] = c_{ijk}Z_k$ (i.e., Y_i and Z_i are "vector operators"), and if V_i are defined by the relation $V_i = d_{ijk}Y_jZ_k$, then $[X_i, V_j] = c_{ijk}V_k$, so that V_i is again a vector operator.

These vector operators are of interest in constructing a complete set of independent invariants for the Lie algebra of SU(n) [cf. L. C. Biedenharn, J. Mathematical Phys. **4** (1963), 436–445; MR **26** #5097].

Hochschild, G. 3585

Ample algebras of representative functions on real analytic groups.

Topology **3** (1964), *suppl.* 1, 119–123.

Soit G un groupe analytique réel et soit $F(G)$ l'algèbre des fonctions représentatives continues à valeurs réelles sur G. Si $F(G)$ sépare les points de G, l'algèbre $F(G) \otimes \mathbf{C}$ complexifiée de $F(G)$ s'identifie à l'algèbre des fonctions représentatives holomorphes sur le groupe G^+ complexification linéaire universelle de G. Une sous-algèbre F de $F(G)$ est dite "ample" si (1) F sépare les points de G, (2) F contient les scalaires, (3) F est stable par les translations (droites et gauches) de G ainsi que par l'involution $s \to s^{-1}$. L'auteur démontre que, si $F(G)$ est engendrable par un nombre fini d'éléments et sépare les points de G, il existe une correspondance de type galoisien entre les sous-algèbres amples de $F(G)$ et les sous-groupes centraux finis Γ de G^+ qui sont stables par la conjugaison canonique dans G^+ et vérifient la condition $\Gamma \cap G = (1)$. Cette correspondance associe à un sous-groupe Γ de G^+ la sous-algèbre constituée par les $f \in F(G)$ telles que $f(xy) = f(y)$ quels que soient $x \in \Gamma$ et $y \in G^+$ lorsque f est considérée comme une fonction sur G^+. En utilisant cette correspondance, l'auteur montre qu'avec les hypothèses faites sur $F(G)$, le nombre des sous-algèbres amples est fini. *J. L. Koszul* (Grenoble)

Vainberg, Ju. R. 3586

On the reduction of formal groups with respect to a prime modulus. (Russian)

Sibirsk. Mat. Ž. **4** (1963), 1263–1270.

Lazard [C. R. Acad. Sci. Paris **239** (1954), 942–945; MR **16**, 219] has proved that every one-parameter formal Lie group $f(x, y) \in A[[x, y]]$ over an integral domain A is abelian. For short, call $f(x, y)$ a group over A. If $A = \mathbf{Q}$, and if all the coefficients of $f(x, y)$ are p-integral, reducing these coefficients modulo p yields a group $\bar{f}$ over GF(p). Considering $\bar{f}$ as a group over the algebraic closure of GF(p), $\bar{f}$ is isomorphic to exactly one of a family of groups $G_{1,m}(p)$, $m \in M = \{0, 1, 2, \cdots, \infty\}$, by a classification theorem of Lazard [Bull. Soc. Math. France **83** (1955), 251–274; MR **17**, 508] and Dieudonné [Amer. J. Math. **77** (1955), 218–244; MR **16**, 789; Math. Z. **63** (1955), 53–75; MR **17**, 174]. Let π be any set of primes; to each $p \in \pi$ assign an arbitrary $m_p \in M$. Then the author proves that there exists a group $f(x, y)$ over $\mathbf{Q}$ such that for each $p \in \pi$, f can be reduced modulo p to yield a group isomorphic to $G_{1,m_p}(p)$, while for each $p \notin \pi$ not all coefficients of $f(x, y)$ are p-integral. The proof uses the methods of the second Lazard paper to construct $f(x, y)$. The author also reformulates the definition of "group over A" in terms of a coproduct on $A[[x]]$.

Sulle costanti delle condizioni di Hölder in forma integrale.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 460–462.

If $\phi(t)$ is a function of the real variable t, defined and

summable in $a \leq t \leq b$ and identically equal to zero outside the same interval, then it is known that

$$\int_a^b |\phi(t+h)-\phi(t)|\,dt = o(|h|) \qquad (h \to 0)$$

if and only if there exists a number c such that $\phi(t)=c$ almost everywhere.

Also

$$\int_a^b |\phi(t+h)-\phi(t)|\,dt = O(|h|) \qquad (h \to 0)$$

if and only if $\phi(t)$ is a function of a finite variation almost everywhere in $a \leq t \leq b$.

Here the author studies the integral

$$I(\phi) = \int_0^1 |\phi(t \pm h)-\phi(t)|\,dt, \qquad \phi(t) = |t|^{\alpha-1}\psi(t)$$

for $h \to 0^+$. Of the four theorems stated in this paper, the following is characteristic: If $\psi(t) \to 0$ as $t \to 0$, and $\psi(t)$ satisfies the condition of W. H. Young in $0<t<1$, viz., $\int_0^1 |d(u\psi(u))|$ is finite, $\int_0^\eta |d(u\psi(u))| = O(\eta)$ for $\eta \to 0^+$, then, for $\varepsilon>0$ and $0 \leq h \leq h_0(\varepsilon)$,

$$I(\phi) < \{K(\psi,\alpha)+\varepsilon\}\bar{\psi}^{1-\alpha}(\lambda)\cdot h^\alpha,$$

where $K(\psi,\alpha)=2/\alpha+H_\alpha$, $\lambda=\sup u(\bar{\psi}(u)\cdot u \leq h)$, and $\bar{\psi}(t)=\sup_{0<u<t}|\psi(u)|$, $H_\alpha=\sigma_1 \lim_{\eta\to 0} \bar{H}(\eta,\sigma)$,

$$\sigma_1 = (1+\sigma)^{1-\alpha}/\{(1+\sigma)^{1-\alpha}-1\}$$

$$\bar{H}(\eta,\sigma) = \sup_{0<u\leq\eta} V_\psi(u/(1+\sigma),u),$$

$V_\psi(a,b)$ being the total variation of $\psi(t)$ in the interval $a \leq t \leq b$, $\sigma>0$, and $0<\eta<1$. *S. K. Chatterjea* (Calcutta)

Rennie, B. C. 3590

On a class of inequalities.

J. Austral. Math. Soc. **3** (1963), 442–448.

In this paper it is shown that the problem of finding the best possible inequality in a certain class, involving k integrals, is often equivalent to the problem of determining the convex hull of a related set of points in k-dimensional space.

Let $\varphi_1,\cdots,\varphi_k$ be given continuous functions on the product space $S_1\times\cdots\times S_r$, and let $f_1,\cdots,f_r$ be measurable functions on the set E, which is either $(0,1)$ or $(-\infty,\infty)$, with respective ranges restricted to $S_1,\cdots,S_r$. For each such $f_1,\cdots,f_r$, let $u_i=\int_E \varphi_i(f_1,\cdots,f_r)\,dx$, and let C be the set of all points $(u_1,\cdots,u_k)$. It is shown first that C is convex. Next, for $E=(0,1)$, it is shown that the closure of C is the intersection of all the half-spaces $\{u; a_1u_1+\cdots+a_ku_k \geq a_0\}$ having coefficients such that $a_1\varphi_1(x)+\cdots+a_k\varphi_k(x)\geq a_0$ for all $x \in S_1\times\cdots\times S_r$. For $E=(-\infty,\infty)$, the result is the same except that a_0 is replaced by 0.

The applicability of the results is illustrated by deriving several known inequalities, in particular, the Cargo-Shisha generalization [Cargo and Shisha, J. Res. Nat. Bur. Standards Sect. B **66B** (1962), 169–170; MR **26** #5110] of the Kantorovich inequality.

E. F. Beckenbach (Los Angeles, Calif.)

Einige Ungleichungen über die mit Gewichtsfunktionen gebildeten Mittelwerte.

Monatsh. Math. **68** (1964), 102–112.

In the interval $0<x<\infty$, let $f(x)$, $g(x)$ be positive, and let $\varphi(x)$, $\psi(x)$ be continuous and strictly monotone. For positive vectors $(a)=(a_1,a_2,\cdots,a_n)$, the author investigates the mean-value function

$$M_\varphi[a]_f = \varphi^{-1}\left[\sum_{i=1}^n f(a_i)\varphi(a_i)\Big/\sum_{i=1}^n f(a_i)\right].$$

It is noted that $M_\varphi[a]_f \leq M_\psi[a]_f$ for all positive (a) if and only if $\psi\varphi^{-1}$ is convex for ψ increasing, and is concave for ψ decreasing. Further, $M_\varphi[a]_f \leq M_\varphi[a]_g$ for all positive (a) if and only if $f(x)/g(x)$ is nonincreasing. Applications are made to power means, to the means introduced by the reviewer [Amer. Math. Monthly **57** (1950), 1–6; MR **11**, 422], to homogeneous means, and to the entropy function of information theory.

On an inequality of Opial and Beesack.

Proc. Amer. Math. Soc. **15** (1964), 565–566.

Under the assumptions that $y(x)$ a complex-valued, absolutely continuous function on $(0,a)$ and $y(0)=0$, the author gives a simple proof of the inequality

$$\int_0^a |y(x)y'(x)|\,dx \leq \frac{1}{2}a\int_0^a |y'(x)|^2\,dx$$

established in another way by P. Beesack [Trans. Amer. Math. Soc. **104** (1962), 470–475; MR **25** #3137] as a generalization of an analogous inequality by the reviewer [Ann. Polon. Math. **8** (1960), 29–32; MR **22** #3772] and C. Olech [ibid. **8** (1960), 61–63; MR **22** #3773].

Z. Opial (Kraków)

Gosselin, R. P. 3593

A maximal theorem for subadditive functions.

Acta Math. **112** (1964), 163–180.

In this paper, the author first proves a maximal theorem for subadditive functions and then applies it to a variety of problems.

Let S_R be the solid sphere of radius R in E_n. The function ϕ is here said to be subadditive on S_R if there exists a constant $C>0$ such that $\phi(u+v)\leq C[\phi(u)+\phi(v)]$ for all $u, v \in S_R$, and to be subadditive-even there if, in addition, $\phi(u)\leq C[\phi(u+v)+\phi(v)]$ for all $u, v \in S_R$. The maximal function $\omega(t)$ corresponding to a given subadditive-even function ϕ on S_R is defined by $\omega(t)=\sup_{|v|\leq t}\phi(v)$, $t\in(0,R)$; then $\omega(t)$ is also subadditive-even, and is finite and nondecreasing. The maximal theorem for subadditive-even functions ϕ on S_R in E_n is expressed by the inequality

$$\int_0^R \frac{\omega^p(t)}{t^{1+p\alpha}}\,dt \leq C\int_{S_R}\frac{\phi^p(u)}{|u|^{n+p\alpha}}\,du$$

for all real α and all p, $0<p\leq\infty$.

Applications are made to known subadditive functions, to integral transforms, and to sums and integrals involving subadditive functions.

Differential and integral inequalities.

Proc. Amer. Math. Soc. **15** (1964), 715–716.

Elementary proofs are given of the following.

Let $Tu = du/dt - a(t)b(u)$, $b > 0$, a and b continuous, and let $A(t) = \int_0^t a(s)\,ds$, $B(y) = \int_\delta^y [b(s)]^{-1}\,ds$. (1) If $Tu \leq 0 \leq Tv$ and $u(0) \leq v(0)$, then $u \leq v$. (2) If $Tu \leq 0$ and $u(0) \leq v(0) = \delta$, then $u \leq B^{-1}[A(t)]$. (3) If $a \geq 0$ and b is monotone non-decreasing, then $w \leq \delta + \int_0^t a(s)b[w(s)]\,ds$. (An example shows that the monotony of b cannot be dropped.)

Let u and v be vectors with any convenient norm and let $Tu = du/dt - f(t, u)$, f a vector. (4) If $\|f(t, u) - f(t, v)\| \leq a(t)b(w)$, $w = \|u - v\|$ and for $t = 0$, $Tu = Tv$ and $\|u - v\| = \delta$, then

$$B^{-1}[-A(t)] \leq \|u - v\| \leq B^{-1}[A(t)].$$

(3) sharpens an inequality of Bihari and (4) sharpens an inequality of Bihari and Langenhop [see E. F. Beckenbach and R. Bellman, *Inequalities*, pp. 133–136, Springer, Berlin, 1961; MR 28 #1266].

A. E. Danese (Buffalo, N.Y.)

Kotljar, B. D. 3595

On quasi-smooth functions of two variables. (Russian)
Ukrain. Mat. Ž. **16** (1964), 383–385.

A function $f(x, y)$ defined in a domain D is quasi-smooth in D if for some $K > 0$

$$(*) \quad \left| f(x, y) - 2f\left(\frac{x + x'}{2}, \frac{y + y'}{2}\right) + f(x', y') \right| \leq K\sqrt{((x - x')^2 + (y - y')^2)}$$

for all (x, y), $(x', y') \in D$; it is quasi-smooth in y in D if $(*)$ holds under the restriction that $x = x'$. Similarly, the quasi-smoothness in x is defined. The result: If D is a rectangle with sides parallel to the coordinate axes and if $f(x, y)$ is bounded, then from the smoothness in both variables x and y follows the smoothness of $f(x, y)$ in D.

The same remains true if D is taken to be the entire plane. However, a similar result is not known for other types of domains. *H. Fast* (Notre Dame, Ind.)

Henkin, G. M. 3596

Linear superpositions of continuously differentiable functions. (Russian)
Dokl. Akad. Nauk SSSR **157** (1964), 288–290.

Let $p_m(x_1, x_2)$ be continuous and $q_m(x_1, x_2)$ continuously differentiable fixed functions defined on the whole plane (x_1, x_2), $m = 1, 2, \cdots, N$. Let D be a domain in that plane and $C(D)$ the space of continuous functions on D. Then (1) functions of the form $\sum_{m=1}^N p_m(x_1, x_2) f_m(q_m(x_1, x_2))$ constitute a non-dense subset of the $C(D)$ as the $f_m(t)$ run over all continuous functions of one variable; (2) for certain integers μ and ν, $\sum_{m=1}^N p_m(x_1, x_2) f_m(q_m(x_1, x_2)) \not\equiv (x_1 + \nu x_2)^\mu$, $(x_1, x_2) \in D$, as the $f_m(t)$ run over all the bounded measurable functions of one variable. The results extend those of Vituškin. Proofs are indicated.

Fiala, Jiří 3597

Representations of generalized measures by integrals.
Comment. Math. Univ. Carolinae **4** (1963), 153–156.

Let $\phi(u)$ be an N-function, i.e., $\phi(u) = \int_0^{|u|} p(t)\,dt$, where $p(t)$ is a non-decreasing function which is positive for $t > 0$, right continuous for $t \geq 0$ and satisfies the conditions $p(0) = 0$ and $\lim_{t\to\infty} p(t) = \infty$. Further, let (X, S, μ) be a finite measure space in which there exists a decreasing sequence of sets $\{E_n\}_{n=1}^\infty$ for which $\mu(E_n) > 0$ for all n, $\bigcap_{n=1}^\infty E_n = \varnothing$, and $\lim_{n\to\infty} \mu(E_n) = 0$. Finally, let $L_\phi(X, S, \mu)$ denote the Orlicz class of real functions on X, i.e., $f \in L_\phi(X, S, \mu)$ if $\int_X \phi(f)\,d\mu < \infty$.

The author proves the following generalization of a classical result of F. Riesz [F. Riesz and B. Sz.-Nagy, *Functional analysis*, p. 75, Ungar, New York, 1955; MR 17, 175]. Theorem: A σ-finite measure ν on S can be represented $\nu(E) = \int_E f\,d\mu$ for $f \in L_\phi(X, S, \mu)$ if and only if there exists a constant C so that for each finite partition $\{E_n\}_{n=1}^N$ of X, $\mu(E_n) > 0$, the following inequality holds:

$$\sum_{n=1}^N \mu(E_n)\phi\left(\frac{\nu(E_n)}{\mu(E_n)}\right) \leq C.$$

Moreover,

$$\int_X \phi(f)\,d\mu = \sup \sum_{n=1}^N \mu(E_n)\phi\left(\frac{\nu(E_n)}{\mu(E_n)}\right),$$

where the supremum is taken over all finite partitions of X. *R. G. Douglas* (Ann Arbor, Mich.)

Alcune osservazioni sopra il problema del prolungamento di misure relative da reticoli d'insiemi.
Matematiche (Catania) **18** (1963), 83–97.

Let $\mathfrak{R}$ be a set of subsets of a given set S which contains the empty set and is closed under the operations of taking finite unions and finite intersections. Let ϕ be a real-valued function defined on $\mathfrak{R}$. This paper contains several theorems of the following type. Assume that $\mathfrak{R}$ possesses certain properties and let $\mathfrak{R}_*$ be the smallest set of subsets of S which contains $\mathfrak{R}$ and possesses designated completeness properties. Then if ϕ possesses the additivity and continuity properties in a given class Q, it is shown that ϕ has a unique extension ϕ_* to $\mathfrak{R}_*$ which possesses properties in a class containing Q. Formulas for ϕ_* are given in terms of the components in a Jordan type decomposition of ϕ.

Appling, William D. L. 3600

Interval functions and continuity.

Rend. Circ. Mat. Palermo (2) **11** (1962), 285–290.

Theorem: If n is a positive integer, $\{[t_k, u_k]\}_{k=1}^{n}$ is a sequence of number intervals, and F is a real-valued function on the interval $[t_1, u_1; \cdots; t_n, u_n]$, then the following two statements are equivalent: (1) If g is a real-valued function on $[a, b]$ having bounded variation and $\{H_k\}_{k=1}^{n}$ is a sequence of functions of subintervals of $[a, b]$ such that for each positive integer $k \leq n$, the set of values of H_k is a subset of $[t_k, u_k]$ and the Hellinger integrals $\int_{[a,b]} H_k(I)\, dg$ exist, then $\int_{[a,b]} F[H_1(I), \cdots, H_n(I)]\, dg$ exists; and (2) F is continuous. Hints to the proof. (a) (2) implies (1) for $n = 1$. Using previous results [Duke Math. J. **29** (1962), 515–520; MR **25** #4075; Proc. Amer. Math. Soc. **13** (1962), 784–788; MR **25** #5150] the author shows that if the interval function $H = H_1$ is bounded and Hellinger g-integrable, then $|H|$ is also. For any $c > 0$ there exists a function G on $[t, u]$ such that $|G(x) - F(x)| < c$ and $G(H)$ is g-integrable. The integrability of $F(H)$ follows. (b) The falsity of (2) implies that of (1). The existence of a point of discontinuity for F enables the construction of some g and $H_1, \cdots, H_n$ for which $F(H_1, \cdots, H_n)$ is not g-integrable. (c) (2) implies (1). This is established by induction on n. A similar approximation as in (b) with respect to x_{n+1} is used.

Barbuti, Ugo 3602

Sulla nozione di misurabilità.

Matematiche (Catania) **18** (1963), 59–72.

Pour prolonger un contenu λ fini, σ-additif, défini sur un anneau booléen $\mathfrak{A}$ d'ensembles, en une mesure m, on peut, s'inspirant de Lebesgue, prolonger d'abord λ sur $\mathfrak{A}_\sigma$ et $\mathfrak{A}_\delta$, puis définir les ensembles mesurables et leurs mesures au moyen d'insertion à ε près (ε quelconque > 0) entre un ensemble de $\mathfrak{A}_\delta$ et un de $\mathfrak{A}_\sigma$. Une autre méthode, dite de Carathéodory, définit une mesure extérieure μ^* à partir de λ sur l'ensemble des parties d'ensembles de $\mathfrak{A}_\sigma$; m est alors la restriction de μ^* aux ensembles mesurables selon Carathéodory. L'auteur envisage deux "prémesures" $\nu|\mathfrak{H}$ et $\mu|\mathfrak{K}_\sigma$ réglementées par des axiomes et en déduit ensembles mesurables I et mesure $m(I)$ tels que: pour tout $\varepsilon > 0$ il existe un $H \in \mathfrak{H}$ et un $K \in \mathfrak{K}_\sigma$ tels que $\mu(K) - \nu(H) < \varepsilon$, $m(I) = \sup\{\nu(H) : H \in \mathfrak{H}, H \subseteq I\} = \{\inf\{\mu(K) : K \in \mathfrak{K}_\sigma, K \supseteq I\}$. Les schémas de Lebesgue et de Carathéodory sont alors interprétés comme des cas particuliers de ce schéma général, par choix convenable des prémesures. D'autres exemples de prolongement d'une fonction λ définie sur un treillis y sont aussi insérés.

Expository.

Collins, H. S. 3604

Characterizations of convolution semigroups of measures.

Pacific J. Math. **14** (1964), 479–492.

For a compact Hausdorff S, $B(S)$ denotes the non-negative, regular Borel measures, of norm ≤ 1, $P(S)$ denotes those measures of norm 1, each provided with the weak-* topology. When S is a topological semigroup, then $P(S)$ and $B(S)$ become compact affine topological semigroups using convolution.

Let K denote a compact convex subset of some real Hausdorff linear space, let $L(K)$ denote the continuous real affine functions on K, and let $E(K)$ denote the extreme points of K. Theorem 2.1: Suppose $L(K)$ separates points of K; then K is the external image of some $P(S)$ if and only if $E(K)$ is compact. It is shown in particular (Theorem 2.2) that K is the continuous affine bicontinuous image of some $P(S)$ if and only if $E(K)$ is compact and K is a simplex (in the sense of Choquet [C. R. Acad. Sci. Paris **243** (1956), 555–557; MR **18**, 288] or Loomis [Amer. J. Math. **84** (1962), 509–526; MR **26** #2575]).

These characterizations of extremal images of $P(S)$, one-one bicontinuous images of $P(S)$, and one-one bicontinuous affine images of $B(S)$, are extended to the case of homomorphic images when S is a compact semigroup, for example (Theorem 3.1), if $L(K)$ separates points of K, then K is an extremal homomorphic image of some $P(S)$ if and only if $E(K)$ is a compact semigroup. Theorem 3.2: K is the one-one bicontinuous and isomorphic image of some $P(S)$ if and only if $E(K)$ is a compact semigroup and K is a simplex.

Kagan, A. M.; Sudakov, V. N. 3605

Separating partitions for certain families of measures. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **19** (1964), no. 3, 147–150.

Let $P = \{P_\theta; \theta \in \Theta\}$ be a family of probability measures on $\{X, A\}$, such that $P_{\theta'} = P_{\theta''}$ implies $\theta' = \theta''$. Let $A_1, A_2, \cdots, A_s$ be disjoint subsets, $A_i \in A$ for $i = 1, 2, \cdots, s$, such that their union equals X. If s equalities $P_{\theta'}(A_i) = P_{\theta''}(A_i)$ for $i = 1, 2, \cdots, s$ imply $\theta' = \theta''$, then the subsets A_i are said to form a partition of X separating the family P. The following theorems are proved. Theorem 1: If the family P is composed of a finite number s of arbitrary distributions, then partitions separating P exist composed of $r \leq s$ elements. Theorem 2: If P is a denumerable family of continuous distributions, then in order to obtain a separation of P, the sample space X need be partitioned only in two subsets. Theorem 3: If P is the family of distributions uniform on $[0, \theta]$ with $0 < \theta < 1$, then the separation of this family can be achieved with $r = 3$ subsets of the sample space but cannot be achieved with only two. Each separating partition provides means of consistently estimating the parameter point corresponding to the observable random variable.

Cater, S. 3606

Some representation theorems for invariant probability measures.

Illinois J. Math. 8 (1964), 408–418.

Let X be a set, T a mapping of X into X, $\mathfrak{F}$ a σ-algebra of subsets of X such that $A \in \mathfrak{F}$ implies $T^{-1}A \in \mathfrak{F}$. A probability measure m on $\mathfrak{F}$ is invariant if $m(A) = m(T^{-1}A)$ for $A \in \mathfrak{F}$, and ergodic if $m[\bigcup_{-\infty}^{\infty} T^i A] = 0$ or 1 for $A \in \mathfrak{F}$. The author considers the problem of integral representations of invariant probability measures in terms of ergodic invariant probability measures. He gives conditions which generalize the work of the reviewer and Hanson [Pacific J. Math. **10** (1960), 1125–1129; MR **24** #A3260] and of Farrell [Illinois J. Math. **6** (1962), 447–467; MR **27** #265].

Three theorems are proved which are somewhat too involved to state here. Several examples are constructed to illustrate the applications of these theorems.

Tsurumi, Shigeru 3607

Ergodic theorems. (Japanese)

Sûgaku **13** (1961/62), 80–88.

This is an expository article on the recent development on ergodic theorems. The author first explains briefly how the ergodic theorems of G. D. Birkhoff and J. von Neumann have been generalized by various people in the past thirty years, and then presents the detailed proof, following the paper of E. Hopf [J. Reine Angew. Math. **205** (1960/61), 101–106; MR **23** #A3234], of the generalized ergodic theorem of Chacon and Ornstein. Using the maximal ergodic lemma of Chacon and Ornstein, which appears in the proof of their generalized ergodic theorem quoted above, the author then shows the proofs of the pointwise and dominated ergodic theorems of Dunford and Schwartz. In the last section of the paper, the author presents his version of random ergodic theorem, which extends and combines all the known random ergodic theorems. A detailed proof of this generalized random ergodic theorem has been published by the author [Ergodic Theory (Proc. Internat. Sympos., Tulane Univ., New Orleans, La., 1961), pp. 259–271, Academic Press, New York, 1963; MR **28** #4086].

Yuji Itô (Providence, R.I.)

Raimi, Ralph A. 3608

Minimal sets and ergodic measures in $\beta N - N$.

Bull. Amer. Math. Soc. **70** (1964), 711–712.

Let βN be the Stone-Čech compactification of the discrete space N of positive integers. The mapping $n \to n+1$ of N extends uniquely to a continuous mapping t of βN onto βN. The restriction of t to $N^* = \beta N - N$ is a homeomorphism of N^* onto N^*. Using a theorem of Rudin [Duke Math. J. **25** (1958), 197–204; MR **20** #4774] it is shown that every set $S \subset N^*$ that is t-invariant, compact, nonempty, and minimal with respect to these properties, is the support of at least two ergodic t-invariant Borel probability measures.

J. C. Oxtoby (Bryn Mawr, Pa.)

Parry, W. 3609

Representations for real numbers.

Acta Math. Acad. Sci. Hungar. **15** (1964), 95–105.

While in previous papers on f-expansions [see C. I. Everett, Jr., Bull. Amer. Math. Soc. **52** (1946), 861–869; MR **8**, 259; B. H. Bissinger, ibid. **50** (1944), 868–876; MR **6**, 150; the reviewer, Acta Math. Acad. Sci. Hungar. **8** (1957), 477–493; MR **20** #3843] only sufficient conditions of a metric character on the function f have been given for the validity of the f-expansion, in § 1 of this paper a necessary and sufficient condition (of a topological nature) is given. § 2 deals with the f-expansions corresponding to mod 1 linear functions. Let us consider the linear mod 1 transformation $T(x) = (\beta x + \alpha)$, where $\beta > 1$, $0 \leq \alpha < 1$, and (y) denotes the fractional part of y. It is shown that, by putting

$$h(x) = \sum_{x < T^n(1)} \frac{1}{\beta^n} - \sum_{x < T^n(0)} \frac{1}{\beta^n},$$

the (signed) measure $\nu(E) = \int_E h(x)\,dx$ is invariant under T. It is shown further that if T is strongly ergodic (i.e., $T^{-1}E \subset E$ implies $l(E) = 0$ or $l(E) = 1$, where $l(E)$ denotes Lebesgue measure), then $h(x) \geq 0$. It remains an open question whether $h(x)$ ever assumes negative values. The author mentions also the following further unsolved problems. Are linear mod 1 transformations always ergodic? If there exists a finite measure invariant under T and equivalent to Lebesgue measure, is T strongly ergodic?

A. Rényi (Budapest)

Gähler, Werner 3610

Flächen in topologischen Räumen.

Math. Nachr. **26** (1963), 181–228.

In the present paper the author develops a theory leading to an abstract extension of the concept of Lebesgue area for Fréchet surfaces S in any topological space R. The general concept of Fréchet surface S is introduced, as usual, as an equivalence class of continuous single-valued mappings $f: M_\sigma \to R$ from plane, closed, simply connected Jordan regions M_σ into R (representations of S). The equivalence of two such mappings f, f' is characterized by the possibility of approaching, say f, by means of homeomorphic transformations $f'h$ of f', or equivalently, by matching f' and f by means of multiple-valued transformations. The theory is based on a subtle topological preparation. Two basic spaces are first taken into consideration. One is the family M_σ, $\sigma \in K$, of all simply connected Jordan regions M_σ of a Euclidean plane, each M_σ being endowed with the induced Euclidean topology. Another is the family $M_{(\sigma,t)}$, $(\sigma, t) \in K$, of all vertices of the triangulations T of the regions M_σ, each $M_{(\sigma,t)}$ being endowed with the discrete topology. The author then proceeds with the definition of Fréchet surfaces in R, those being of the oriented, or non-oriented type, proper surfaces S, or polyhedral surfaces P. Then a proper surface S possesses at least a representation $p \mid M_\sigma$ from a Jordan region M_σ; a polyhedral surface possesses at least a representation $p \mid M_{(\sigma,t)}$ from a discrete set $M_{(\sigma,t)}$. If $\mathfrak{S}$ is the set of all proper surfaces S, and $\mathfrak{P}$ the set of all polyhedral surfaces P, then the union $\mathfrak{R} = \mathfrak{S} \cup \mathfrak{P}$, equipped with a convenient topology, is proved to be a topological space, and even a metric space if R is metric. In any case the subset $\mathfrak{P}$ of $\mathfrak{R}$ is everywhere dense in $\mathfrak{R}$. If $\eta(P)$, $P \in \mathfrak{P}$, is any single-valued real-valued function on $\mathfrak{P}$, then an area-like functional on $\mathfrak{R}$ can be defined by taking

$$\alpha(S) = \sup_{U \in B} \inf_{P \in U \cap \mathfrak{P}} \eta(P), \qquad S \in \mathfrak{R},$$

where B is any system of neighborhoods of S in $\mathfrak{R}$. This functional $\alpha(S)$ is then lower semicontinuous in $\mathfrak{R}$. In

particular, the author considers a single-valued real-valued function $\tau(abc)$ from the triples abc of points of R into the reals, satisfying the following axioms: (1) $\tau(abc)=0$ if $a=b$; (2) $\tau(abc)=\tau(bca)$, and, for oriented surfaces only, (2') $\tau(abc)=\tau(cba)$. Then, for any polyhedral surface P an elementary area $\eta(P)$ can be defined by taking

$$\eta(P) = \sum \tau(p(e_j^1)p(e_j^2)p(e_j^3)),$$

where $\sum$ runs over all simplexes $e_j^1e_j^2e_j^3$ of the complex corresponding to a given representation $p|M_{(\sigma,t)}$ of P. This elementary area $\eta(P)$ is proved to be independent of the representation. The corresponding functional $\alpha(S)$ is said to be a generalized Lebesgue area. The functional $\alpha(S)$ is proved to be lower semi-continuous in $\mathfrak{R}$, and $\alpha(S)$ can be equivalently defined by a Lebesgue-like process. Also, $\alpha(S)$ is superadditive, that is, $\alpha(S)\geq\alpha(S_1)+\cdots+\alpha(S_n)$ for any finite subdivision of S into parts all in $\mathfrak{R}$. Finally, an oriented surface S and the corresponding non-oriented one, say S^0, have the same area $\alpha(S)=\alpha(S^0)$. Of course, for any polyhedral surface $P\in\mathfrak{P}\subset\mathfrak{R}$, we have $\alpha(P)\leq\eta(P)$, and in this generality, $\alpha(P)$ may well be smaller than P. Nevertheless, no attempt is made to discuss under which further axioms it is possible to prove the equality $\alpha(P)=\eta(P)$. A previous relevant theory for Lebesgue area for surfaces in Banach or metric spaces is due to E. Silverman [Riv. Mat. Univ. Parma **2** (1951), 47–76; MR **13**, 122].

L. Cesari (Ann Arbor, Mich.)

Silverman, Edward 3611

Geodesics and Lebesgue area.

Proc. Amer. Math. Soc. **15** (1964), 775–780.

Using the concepts of two of his previous papers [Riv. Mat. Univ. Parma **2** (1951), 47–76; MR **13**, 122; ibid. **2** (1951), 195–201; MR **13**, 731], the author defines an area for a discontinuous surface in a metric space which is an extension of Lebesgue area. This enables him to stretch a given continuous surface to its maximum extension. In the event the maximum is continuous, then its Lebesgue area is equal to that of the original surface.

If f is a surface, $f=lm$ its monotone-light factorization, and if $p, q\in$ domain f, then inf {length $l\alpha$: α is continuous on $[0,1]$ into range m, $\alpha(0)=m(p)$, $\alpha(1)=m(q)$} is the pseudo-geodesic distance between p and q under f. Now, if two continuous surfaces are related so that the pseudo-geodesic distances between corresponding points are equal, then the maximum stretched surfaces derived from these two are isometric. This implies that the Lebesgue areas of the two surfaces being stretched are equal.

W. P. Ziemer (Bloomington, Ind.)

Shapiro, Victor L. 3612

Harmonic analysis and the theory of cochains.

Bull. Amer. Math. Soc. **70** (1964), 447–467.

The following theorem is established with methods based on measure theory and Fourier analysis: There is a one-to-one correspondence between local L^1 1-cochains in E^2 and equivalence classes of local L^1 differential forms in E^2. Here a local L^1 1-cochain in E^2 is a linear function on 1-dimensional oriented polyhedral chains in E^2 whose value on 1-simplexes parallel with either the x- or y-axis does not exceed the integral over these simplexes of fixed L^1 functions of one variable, and whose value on the boundary of a 2-simplex, two of whose sides are parallel with the axes, is no more than the integral over that 2-simplex of a fixed L^1 function. A local L^1 differential form is essentially a differential 1-form whose coefficients are measurable functions dominated by fixed L^1 functions of one variable. The correspondence above associates to a local L^1 1-cochain X in E^2, the local L^1 differential form ω by requiring that for most 1-simplexes σ, $X(\sigma)=\int_\sigma\omega$. This theorem is a generalization in these dimensions of Wolfe's theorem [H. Whitney, *Geometric integration theory*, Princeton Univ. Press, Princeton, N.J., 1957; MR **19**, 309], which relates flat cochains and flat differential forms in a similar manner. The author asserts that results similar to those above hold for r-cochains in E^n.

F. J. Almgren, Jr. (Princeton, N.J.)

Marstrand, John M. 3613

The (φ, s) regular subsets of n-space.

Trans. Amer. Math. Soc. **113** (1964), 369–392.

The following theorem in geometric measure theory is established. Let φ be a measure on E_n for which closed sets are measurable. Let $s\geq 0$ and $B\subset A\subset E_n$ with $\varphi(B)>0$. If B is (φ, s) regular with respect to A, then (i) s is an integer, and (ii) φ almost all points of B are weakly tangential with respect to A. Here the (φ, s) regularity of B with respect to A means that for φ almost all points $x\in B$, $\bigcirc_n^s(\varphi, A, x)=\lim_{r\to 0} r^{-s}\varphi(A\cap\{y:|y-x|\leq r\})$ exists, and $0<\bigcirc_n^s(\varphi, A, x)<\infty$. A point $x\in B$ is weakly (φ, s, s) tangential with respect to A if

$$0 = \liminf_{r\to 0} r^{-s}$$
$$\times\varphi(A\cap\{y:|y-x|\leq r; |(y-x)\cdot v_i|>\eta r \text{ for } i=k+1,\cdots,n\})$$

for some orthonormal basis $\{v_1,\cdots,v_n\}$ of E_n and each $\eta>0$. It is not known whether the theorem remains true if "lim inf" is replaced by "lim" above. If it does remain true, then a (φ, s) regular set would be (φ, s) restricted at φ almost all points and hence (φ, s) rectifiable [H. Federer, same Trans. **62** (1947), 114–192; MR **9**, 231]. The theorem is proved by an intricate type of induction combining measure-theoretic and geometric arguments.

★**Boundary-value problems in the theory of functions of a complex variable [Краевые задачи теории функций комплексного переменного].** 3614

Izdat. Kazan. Univ., Kazan, 1962. 80 *pp.* 0.34 *r.*

This small non-periodical pamphlet contains seven papers in the theory of functions of a complex variable and in partial differential equations. The papers will be reviewed individually.

McKiernan, M. A. 3615

On the convergence of series of iterates.

Publ. Math. Debrecen **10** (1963), 30–39.

Let $f^{[0]}(x)=x$, $f^{[n+1]}(x)=f(f^{[n]}(x))$, $n=0,1,2,\cdots$. The author discusses the convergence of the series

$$(*)\qquad \sum_{n=0}^{\infty} a_n \sum_{r=0}^{n}\binom{n}{r}(-\beta)^{n-r}f^{[r]}(x)$$

when $f(z)$ is analytic in the neighbourhood of $z=0$. The results are formulated in terms of the behaviour of the series $h(z)=\sum_0^\infty a_n(z-\beta)^n$ with radius of convergence d. In stating the theorems the author makes use of the following known results on iteration [P. Montel, *Leçons sur les récurrences et leurs applications*, Gauthier-Villars, Paris, 1957; MR **19**, 427]. Let $f(z)$ be regular at $z=0$, $f(0)=0$, $f'(0)=\alpha$, $0<|\alpha|<1$. Then there is a $\rho>0$ and a unique function $F(z)$, the Schröder function for $f(z)$, which is the uniform limit of the sequence $f^{[n]}(z)/\alpha^n$ in some neighbourhood of $z=0$, with $F(0)=0$, $F'(0)=1$, and having an inverse $F^{[-1]}(z)$ in $|z|\leq\rho$ with expansion $\sum_1^\infty c_n z^n$ $(c_1=1)$, and satisfying the equation $F\{f^{[r]}(z)\}=\alpha^r F(z)$, so that $f^{[r]}(z)=\sum_1^\infty c_n\alpha^{rn}[F(z)]^n$ for all integers $r\geq 1$. Also the function $\phi(x;z)=\sum_0^\infty f^{[n]}(x)/z^{n+1}$ is regular in the whole plane except for simple poles at $z=\alpha^n$, $n=1,2,\cdots$, for which $c_n\neq 0$ and the essential singular point $z=0$, in case there are an infinite number of poles. The author has already shown that (*) converges if all the singular points of $\phi(x;z)$ are in the interior of the circle of convergence of $h(z)$ [C. R. Acad. Sci. Paris **246** (1958), 2564–2567; MR **20** #1785]. In this paper the author considers the case when these singularities lie on or outside the circle. He proves that (*) converges uniformly in $|F(x)|\leq\rho$ if $h(z)$ converges uniformly on the singularities of $\phi(x;z)$. If $z=0$ is on the circle of convergence of $h(z)$, then (*) will converge uniformly in $|F(x)|\leq\rho\alpha^{\nu+1}$ if (i) $N^{-\nu}|\sum_1^N a_n\beta^n|$ is bounded in N, and (ii) the other singularities of ϕ lie in the interior of the intersection of $|z-\beta|<|\beta|$ and the sector $\arg\beta-\frac{1}{2}\pi+\varepsilon\leq\arg z\leq\arg\beta+\frac{1}{2}\pi-\varepsilon$ for some $\varepsilon>0$. If $0<\alpha<1$ and $a_n=\binom{s}{n}$, the series (*) converges uniformly in $|F(x)|\leq\rho\alpha$ if $s\geq 0$, and in $|F(x)|\leq\rho\alpha^{1-s}$ if $s<0$, to a function $f^{[s]}(x)$ satisfying the relations $F\{f^{[s]}(x)\}=\alpha^s F(x)$ and $f^{[s]}\{f^{[t]}(x)\}=f^{[s+t]}(x)$ and reducing to the nth iterate when $s=n$ is a positive integer. Also, when $a_n=(-1)^n/n$, the series (*) converges uniformly in $|F(x)|\leq\rho\alpha^{1+\varepsilon}$, for every $\varepsilon>0$, to a function $L(x)=(\log\alpha)F(x)/F'(x)$ and $L\{f(x)\}=L(x)f'(x)$. The author gives a theorem for the series (*) when $-1<\alpha<0$ and another theorem for the series (*) to diverge in $|F(x)|\leq\rho$ except when $F(x)=0$.

Sunyer Balaguer, F. 3616

Generalization of the method of Wiman and Valiron to a class of Dirichlet series. (Spanish)

Rev. Acad. Ci. Zaragoza (2) **16** (1961), no. 1, 9–13.

This paper has appeared elsewhere [Actas 2.ª Reunión Mat. Españoles (1961), pp. 43–47, Sem. Mat. Zaragoza, Zaragoza, 1962; MR **28** #3145].

A. A. Armendáriz (New Orleans, La.)

Pfluger, Albert 3617

Zu einem Verzerrungssatz der konformen Abbildung.

Math. Z. **84** (1964), 263–267.

The author gives a new proof of the following theorem. Let $f(z)=z+a_2z^2+\cdots$ map the unit disc, K, univalently and conformally onto the complex w-plane. In the w-plane denote by D_n the n rays of length $(\frac{1}{4})^n$ drawn from the origin, beginning on the positive real axis, and making equal angles of $2\pi/n$ with each other. Then either at least one of these rays is contained in $f(K)$, or else $f(z)=z/\sqrt[n]{(1+z^n)^2}$, up to a rotation.

This theorem is deduced as a consequence of a more general (known) distortion theorem. The proof of this latter theorem is more analytical than existing ones. It uses a simplified form of the method of extremal length.

J. L. Kazdan (Cambridge, Mass.)

Kalandija, A. I. 3618

On approximate conformal mapping of simply connected regions. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 717–720.

Let C be a closed Jordan curve represented in polar form by the equation $\rho=\rho(\varphi)$, where $\rho(\varphi)$ is continuously differentiable in $[0,2\pi]$ and has the period 2π. Suppose $z=\omega(\zeta)$ maps the disk $|\zeta|<1$ conformally onto the interior of C such that $\omega(0)=0$, $\omega'(0)>0$. The author develops an iteration procedure for the determination of ω, similar to that of Theodorsen. Let C_0 be a closed Jordan curve, star-shaped with respect to the origin and smooth, and suppose that the mapping function $z=\omega_0(\zeta)$, with $\omega_0(0)=0$ and $\omega_0'(0)>0$, of $|\zeta|<1$ onto the interior of C_0 is known. Then, starting with $\omega_0(\zeta)$, successive approximations $\omega_n(\sigma)$ to $\omega(\sigma)$, $\sigma=e^{i\theta}$, are calculated by means of the formula

$$\omega_{n+1}(\sigma)=\omega_n(\sigma)\left\{\frac{\rho[\varphi_n(\theta)]}{|\omega_n(\sigma)|}+\frac{1}{2\pi i}\int_{-\pi}^{\pi}\frac{\rho[\varphi_n(t)]}{|\omega_n(e^{it})|}\cot\frac{t-\theta}{2}\,dt\right\},$$
$$n=0,1,2,\cdots,$$

where $\varphi_n(\theta)=\arg\omega_n(\sigma)$, and the integral is a principal value. The author does not investigate the question of the convergence of the method but remarks that results analogous to those established by the reviewer for Theodorsen's method [the reviewer, Quart. Appl. Math. **3** (1945), 12–28; MR **6**, 207] may be expected. He illustrates the application of the procedure by calculating an approximation to the mapping function of the unit disk onto the interior of an ellipse with semi-axes a and b by taking $\omega_0(\zeta)=\zeta\exp(\alpha\zeta^2+\beta)$, where

$$\alpha=\tfrac{1}{2}\ln(a/b),\qquad\beta=\tfrac{1}{2}\ln(ab)\ (a/b<e).$$

Kühnau, Reiner 3619

Geometrie der konformen Abbildung auf der projektiven Ebene.

Wiss. Z. Martin-Luther-Univ. Halle-Wittenberg Math.-Natur. Reihe **12** (1963), 5–19.

Die projektive Ebene wird hier als Riemannsche Zahlenkugel mit antipodischer Punktepaarung, versehen mit der Metrik der elliptischen Geometrie, realisiert. Den konformen Abbildungen einseitiger Gebiete der projektiven Ebene in die projektive Ebene sind die konformen Abbildungen der entsprechenden Gebiete auf der Riemannschen Zahlenkugel zugeordnet, bei denen antipodische Punkte wieder in antipodische Punkte überführt werden; den konformen Abbildungen zweiseitiger Gebiete entsprechen die konformen Abbildungen von Gebieten der Zahlenkugel ohne antipodische Punktepaare in ebensolche.

Analog zum Fall der Riemannschen Zahlenkugel wird mit Hilfe der Koebe'schen Kontinuitätsmethode die Existenz (und Eindeutigkeit) der konformen Abbildung von endlichfach zusammenhängenden Gebieten der projektiven Ebene auf gewisse Normalgebiete wie Radial- und Kreisbogenschlitzgebiete nachgewiesen. Im Falle einseitiger Gebiete z.B. wird gezeigt: Sind auf der projektiven

Ebene n diametral- und drehungssymmetrische Kurvenscharen S_k, $k=1,\cdots,n$, gegeben, so existiert für jedes n-fach zusammenhängende, die Punkte 0 und z_0 enthaltende Gebiet genau eine konforme Abbildung f mit $f(0)=0$ und $f(z_0)/z_0>0$, sodass die k-te Randkomponente in einen Schlitz auf S_k, $k=1,\cdots,n$, übergeht. Mit Hilfe der Flächenstreifen- oder Extremallängenmethode ergeben sich entsprechende Extremaleigenschaften dieser Abbildungen. Auch das Koebe'sche Kreisnormierungsprinzip wird übertragen.

Es werden anschliessend eine Anzahl Extremalprobleme behandelt, die rationalen quadratischen Differentialen zugeordnet sind.

Shapiro, Harold S. 3620

Weakly invertible elements in certain function spaces, and generators in ℓ_1.

Michigan Math. J. **11** (1964), 161–165.

Let ℓ_1 denote the Banach algebra of complex sequences $a=\{a_n\}$ $(n=0,1,2,\cdots)$ for which $\sum|a_n|<\infty$, multiplication being defined by convolution. A sequence a is said to be a generator of ℓ_1 if the polynomials in a are dense in ℓ_1. A necessary condition for $a=\{a_n\}$ to be a generator is that $f(z)=\sum a_nz^n$ be univalent in $|z|<1$ and map $|z|<1$ onto a Jordan domain.

D. J. Newman, J. T. Schwartz, and H. S. Shapiro [Trans. Amer. Math. Soc. **107** (1963), 466–484; MR **27** #575] proved Theorem A: Let $f(z)=\sum a_nz^n$ be univalent in $|z|<1$ and map $|z|<1$ onto a Jordan domain whose boundary is rectifiable. Let $I(z)$ denote the normalized inner factor of $f'(z)$. Then $a=\{a_n\}$ is a generator of ℓ_1 if and only if $(IH_2)^\perp$ contains no non-null function whose Taylor coefficients are $O(1/n)$. D. J. Newman later showed [Trans. Amer. Math. Soc. (to appear)] that the inner factor I has, in reality, no bearing on the question by proving Theorem B: Let $f(z)=\sum a_nz^n$ be univalent in $|z|<1$ and map $|z|<1$ onto a Jordan domain whose boundary is rectifiable. Then $a=\{a_n\}$ is a generator of ℓ_1.

In the words of the author, "Newman's proof of Theorem B is somewhat complicated, and the main purpose of this note is to provide a rather simple deduction of Theorem B from Theorem A. The proof offered here is essentially a modification of Newman's proof, but has perhaps some interest in view of its simplicity." In the deduction of Theorem B from Theorem A, use is made of the concept of weakly invertible elements in the Hilbert space B_σ of analytic functions $f(z)=\sum a_nz^n$ in $|z|<1$ for which $\sum|a_n|^2/(n+1)^\sigma<\infty$.

The author also (1) proves a theorem which exhibits the quantitative interplay between the rate at which an inner function can tend to zero radially and the "evenness" with which its representing measure is distributed on the unit circle, (2) uses the idea of weak invertibility to show (in terms of a completeness theorem for ℓ_2) that for any inner function I, the Taylor coefficients of an $f\in(IH_2)^\perp$ cannot be too small, unless they vanish from some point on, and (3) points out that the results of the paper can be extended to functions on the half-line $0\le t<\infty$.

Hayden, T. L.; Merkes, E. P. 3621

Chain sequences and univalence.

Illinois J. Math. **8** (1964), 523–528.

Let

$$z\frac{f'(z)}{f(z)}\sim 1-\frac{a_1z^{\alpha_1}}{1}-\frac{a_2z^{\alpha_2}}{1}-\cdots-\frac{a_nz^{\alpha_n}}{1}-\cdots$$

be the C-fraction expansion determined by a fixed formal power series $f(z)=\sum_1^\infty c_nz^n$, $c_1\neq 0$, and let Π_f denote the class of formal power series $g(z)=\sum_1^\infty c_n^*z^n$ for which the C-fraction expansion of $zg'(z)/g(z)$ has exponents $\alpha_n^*=\alpha_n$ and coefficients $|a_n^*|\le|a_n|$. The radius of univalence and the starlike radius for Π_f are, respectively, $U(\Pi_f)$ and $S(\Pi_f)$, where, by definition, $U(\Pi_f)=0$ in case there is a member of Π_f which is not analytic at $z=0$. Continued-fraction convergence and value-region properties are used to show that $r_0\le S(\Pi_f)\le U(\Pi_f)$, where r_0 is the supremum of r for which $\{|a_n|r^{\alpha_n}\}_1^\infty$ is a chain sequence. It is also shown that $r_0=S(\Pi_f)=U(\Pi_f)$ in case the chain sequence has uniquely determined parameters. When $\alpha_n=\alpha$, the relation of the continued fractions to Stieltjes transforms enables the authors to obtain this last result without the unique parameter hypothesis. Results are illustrated by application to Bessel functions.

Sul problema di Bieberbach per le funzioni univalenti.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 469–471.

In this note the author considers the classical Bieberbach conjecture concerning the coefficients of $f(z)=z+a_2z^2+\cdots$, which is assumed to be analytic and univalent in the unit disc K. He studies the limit

$$\liminf_{\mathrm{Re}\,(a_2)\to 2-}\left\{\frac{n-\mathrm{Re}\,(a_n)}{2-\mathrm{Re}\,(a_2)}\right\}\equiv\rho_n$$

and proposes that one should study the analogous limit

$$\liminf_{\mathrm{Re}\,(a_3)\to 3-}\left\{\frac{n-\mathrm{Re}\,(a_n)}{3-\mathrm{Re}\,(a_3)}\right\}\equiv\theta_n.$$

The author obtains the following results. (I) $\rho_2=1$, $\rho_3=0$, $\rho_4>0.80$, $\rho_6>0$ and $\rho_{2m+1}\le 0$. (II) There exists an absolute constant ε such that for each $f(z)=z+a_2z^2+\cdots$, analytic and univalent in K, with $2-\varepsilon<\mathrm{Re}\,(a_2)\le 2$, it follows that $\mathrm{Re}\,(a_4)\le 6$, with equality only for the Koebe function.

Lai, Wan-tsai [Lai, Wan-tsai] 3623

On starlike typically-real functions.

Acta Math. Sinica **13** (1963), 389–404 (*Chinese*); *translated as Chinese Math.* **4** (1964), 423–439.

Let $T(\mu)$ be the class of functions $w=f(z)=z+z^2+\cdots$ regular and typically real in the unit disc, and let $T^*(\mu)\subset T(\mu)$ be the subclass of functions starshaped with respect to $w=0$. In this paper the author evaluates in a manner analogous to that used by J. A. Jenkins [cf. Canad. J. Math. **13** (1961), 299–304; MR **22** #12227] the exact bounds

$$m^*(\mu,z)=\inf|f(z)|,\qquad M(\mu,z)=\sup|f(z)|$$

for fixed z ($|z|<1$) and f ranging over $T^*(\mu)$.
Z. Lewandowski (Lublin)

Waśkiewicz, Jadwiga 3624

Sur certains problèmes extrémaux dans la famille des fonctions univalentes bornées inférieurement dans le cercle $K(\infty, 1)$.

Bull. Soc. Sci. Lettres Łódź 14 (1963), *no.* 3, 30 *pp.*

Consider the class $\sum_p (m)$, $p=1, 2, 3, \cdots$, of holomorphic functions

$$\Phi_p(z) = z+\frac{B_{p-1}^{(p)}}{z^{p-1}}+\frac{B_{2p-1}^{(p)}}{z^{2p-1}}+\cdots, \qquad |z| > 1,$$

which are univalent and are bounded from below, $|\Phi(z)|>m$, $0<m<1$, and which also satisfy the symmetry condition

$$\Phi_p(ze^{2\pi i/p}) = e^{2\pi i/p}\Phi_p(z).$$

The author determines the lower bound of the functional $H(\Phi_2)=|(\Phi_2(z_1)-\Phi_2(z_2))/(z_1-z_2)|$, where $|z_1|=|z_2|>1$. Upper bounds for two other functionals and inexact lower bounds for $H(\Phi_p)$, $p=3, 4, \cdots$, are also found. Previously, these results were only known for $\Sigma_1(m)$. The proofs utilize Loewner's well-known differential equation.

J. L. Kazdan (Cambridge, Mass.)

Bazilevič, I. E. 3625

Generalization of an integral formula for a subclass of univalent functions. (Russian)

Mat. Sb. (*N.S.*) 64 (106) (1964), 628–630.

In this note the author gives a formula for a class of functions $f(z)=z+A_2z^2+\cdots$ which are analytic and univalent in the unit disc K. The formula is the following one.

$$f(z) = \left[\frac{p_0(0)}{p_1(0)}\int_0^z p_1(s)S^{p_0(0)-1}\exp\left(\int_0^s \frac{p_0(t)-p_0(0)}{t}\,dt\right)ds\right]^{1/p_0(0)},$$

where $p_0(z)$ and $p_1(z)$ are analytic and have positive real part in K, and where the proper branch of the function $f(z)$ is taken so as to have the form $f(z)=z+A_2z^2+\cdots$ near $z=0$. The author's proof of univalence depends upon the Loewner equation. The present result contains an earlier one due to the author [same Sb. (N.S.) 37 (79) (1955), 471–476; MR 17, 356].

M. Reade (Ann Arbor, Mich.)

Lewandowski, Z.; Złotkiewicz, E. 3626

Variational formulae for functions meromorphic and univalent in the unit disc.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. 12 (1964), 253–254.

Let $U(p)$, $0<|p|<1$, denote the class of functions $f(z)=z+a_2z^2+\cdots$ which are meromorphic and univalent in the unit disc K and which have a simple pole at $z=p$. Let $\Sigma(p)$ denote the class of functions $F(\zeta)=\zeta+b_0+b_1/\zeta+\cdots$ which are analytic and univalent in the complement of the closure of K and which vanish at $\zeta=1/p$. It is known that $f\in U(p)$ if and only if $[1/f(1/\zeta)]\in\Sigma(p)$. Hence the authors can apply certain variational formulae for $\Sigma(p)$ due to Šlionskiĭ [Vestnik Leningrad. Univ. 13 (1958), no. 13, 64–83; MR 20 #4652] in order to obtain variational formulae for the class $U(p)$. These last are of "Schiffer type". The authors give one application, which is that of finding a differential equation for the function in $U(p)$ that yields the maximum of the absolute value of the nth Taylor coefficient at $z=0$; they recapture an earlier result due to Komatu [Proc. Japan Acad. 21 (1945), 269–277; MR 11, 170; ibid. 21 (1945), 278–284; MR 11, 170].

M. Reade (Ann Arbor, Mich.)

Aleksandrov, I. A. 3627

Extremal properties of the class $S(w_0)$. (Russian)

Trudy Tomsk. Gos. Univ. Ser. Meh.-Mat. 169 (1963), 24–58.

The author is concerned with the class $S(z_0)$ of functions $f(z)=a_1z+a_2z^2+\cdots$ regular and univalent in the unit disc which satisfy $f(z_0)=z_0$. He derives variational formulae for the class $S(z_0)$, and, using these, he determines the domains of variability of the functionals

$$I_1(f) = \mathcal{J}_1\left[\frac{f''(z)}{f'(z)}, \overline{\frac{f''(z)}{f'(z)}}\right]$$

and

$$I_2(f) = \mathcal{J}_2[f(z), \overline{f(z)}, f'(z), \overline{f'(z)}]$$

for fixed z and fixed functions $\mathcal{J}_k$ satisfying some regularity conditions. Making $z_0\to 0$, he obtains some new results for the class S.

Weyl, Hermann 3628

★The concept of a Riemann surface.

Translated from the third German edition by Gerald R. MacLane. ADIWES International Series in Mathematics.

Addison-Wesley Publishing Co., Inc., Reading, Mass.-London, 1964. xi+191 *pp.* $12.50.

Since the third edition of Weyl's celebrated monograph has already been reviewed at length [*Die Idee der Riemannschen Fläche*, dritte Auflage, Teubner, Stuttgart, 1955; MR 16, 1097], it suffices to note that the present translation into English by Professor Gerald MacLane is a lucid rendition of the original. The typography is excellent. The publication of this translation is a great service to the mathematical community in the English-speaking countries.

M. H. Heins (Urbana, Ill.)

Mori, Mineko 3629

Canonical conformal mappings of open Riemann surfaces.

J. Math. Kyoto Univ. 3 (1963/64), 169–192.

The author first proves that an arbitrary open Riemann surface of genus $g>1$ is conformally equivalent to an at most g-sheeted covering surface of the extended plane which is bounded by a set consisting of analytic curves and a totally disconnected set. The main theorems show that an arbitrary open Riemann surface R of finite genus $g>0$ can be mapped onto a $(g+1)$-sheeted covering surface of the extended plane. The total area of the projection of the boundary of the image of R under this mapping is zero. The mapping can either be selected to have all $g+1$ of its poles at a single point of R or at $g+1$ distinct points. A similar theorem is proved for the circular or radial slit mappings, in which the logarithmic area of the projection of the boundary of the image is zero.

Rigidity of projection map and the growth of analytic functions.

Kôdai Math. Sem. Rep. **16** (1964), 40–43.

This paper contains a proof of a composition theorem due to the reviewer [Ann. of Math. (2) **55** (1952), 296–317; MR **13**, 643] and gives examples of concrete Riemann surfaces on which the algebroid functions of low order reduce to the composition of a meromorphic function on the plane and the projection map. An example of a transcendental hyperelliptic Riemann surface on which the Denjoy-Carleman-Ahlfors theorem persists is also given.

M. H. Heins (Urbana, Ill.)

Siciak, J. 3631

Some applications of the method of extremal points.

Colloq. Math. **11** (1963/64), 209–250.

Let E be a bounded closed set in the complex plane C, and $b(z)$ a bounded real-valued function defined on E. The author uses the method of extremal points (introduced first by Fekete in 1923) to define an extremal function $\Phi(z, E, b)$, which he proves is equal to a similar function defined by Leja. "The advantage of our definition of Φ relies on the fact that it admits a straightforward generalization to the case of the space C^n of n complex variables."

Proofs of old and new properties of Φ are given, and then are applied to the effective construction of a generalized—in the sense of Kellogg and Wiener, or Perron—solution of the Dirichlet problem. Lagrange's interpolation formula and the maximum principle for subharmonic functions are the major tools.

J. L. Kazdan (Cambridge, Mass.)

Bach, W. 3632

On some extremal functions of Leja in the space.

Colloq. Math. **11** (1963/64), 251–255.

Let $\omega(p, q)$ be a continuous function defined on the Cartesian product $E^{(m)} \times E^{(m)}$, where $E^{(m)}$ is the Euclidean m-space. Suppose, moreover, that $\omega(p, q) \geq 0$, $\omega(p, p) = 0$, $\omega(p, q) = \omega(q, p)$. Let E be a compact subset of $E^{(m)}$ and suppose that the system $q^{(n)} = \{q_0, q_1, \cdots, q_n\}$ of points $q_k \in E$ maximizes the expression $V(p^{(n)}) = \prod \omega(p_j, p_k)$ for $0 \leq j < k \leq n$. In connection with some results of F. Leja ($\omega = |p-q|$, $m = 2$) the author investigates the limits $\log A_n(r)/n$, $\log B_n(r)/n$ for $n \to \infty$, where

$$A_n(r) = \max_j \prod_{\substack{k=0\\k\neq j}}^{n} \frac{\omega(r, q_k)}{\omega(q_j, q_k)},$$

$$B_n(r) = \inf_{p^{(n)} \subset E} \left\{ \max_j \prod_{\substack{k=0\\k\neq j}}^{n} \frac{\omega(r, p_j)}{\omega(p_k, p_j)} \right\}$$

with $\omega = \exp(-|p-q|^{2-m})$, $m \geq 3$.

Z. Lewandowski (Lublin)

Edrei, Albert; Fuchs, Wolfgang H. J. 3633

On the zeros of $f(g(z))$ where f and g are entire functions.

J. Analyse Math. **12** (1964), 243–255.

The authors ask the following general question, answer it under various auxiliary hypotheses, and give some striking applications. Question: If g is an entire function, let $M(r) = M(r, g)$ denote its maximum modulus for $|z| = r$. For large $|w|$ define t by $|w| = M(t, g)$. Is it possible to find a function $\varphi(t)$ such that $g(z) = w$ has a solution in $|z| < \varphi(t)$ provided $|w|$ is sufficiently large (depending on g and φ)? Answers: If g (not a polynomial) is of finite order and $\xi > 0$, we can take $\varphi(t) = t^{1+\xi}$. If g is of positive lower order and there are r_1 and B such that

$$\log M\{r(1 + (\log M(r, g))^{-1/2})\} < (\log M(r))^B \qquad (r > r_1),$$

we can take $\varphi(t) = t\{1 + 2(\log M(t, g))^{-1/2}\}$. If g is odd and not a polynomial, we can take $\varphi(t) = (1+\xi)t$. The first answer has the following applications. If f and g are entire, the zeros of f have positive exponent of convergence, and g is not a polynomial, then the zeros of $f(g(z))$ do not have finite exponent of convergence. If F is meromorphic and not of order 0, and g is entire, not a polynomial, then $F(g(z))$ is of infinite order. This last result implies, in particular, Pólya's theorem that except in the obvious cases an entire function of an entire function is of infinite order [J. London Math. Soc. **1** (1926), 12–15], providing a proof that is quite elementary (in particular, independent of Schottky's theorem). The basic tool of the paper is the following lemma. Let $g(z) = \sum c_k z^k$ be regular in $|z| < R$ and omit the value w. Then if $\max\{2|g(0)|, 4\} < 2M(r, g) \leq |w|$, we have $|c_n| r^n < 6|w|(r/R)^n \log M(r, g) + |w|^{-1} M^2(r, g)$.

Roux, Delfina 3635

Su una classe di funzioni intere con il minimo modulo quasi-asintotico al massimo modulo.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 12–16.

With the usual notations, the author shows that if $f(z)$ is an entire function (of order 0) such that $\sup_{x \geq r} x^{-k} n(x) = o(r^{-k} \log M(r))$, where $0 < k < 1$, then $\log M(r) \sim N(r)$ and $\log m(r)$ is quasi-asymptotic to $\log M(r)$; this last means that for each $\varepsilon > 0$ the set where $(1-\varepsilon)\log m(r) < \log M(r) < (1+\varepsilon)\log m(r)$ has linear density 1. In particular, the author's hypothesis is shown to hold if $\log M(r) = O((\log r)^2)$, or if $(\log r)^{\alpha - c} < \log M(r) < (\log r)^{\alpha}$, $\alpha > 1$, $0 < c < 1$ [condition used by S. K. Singh and K. Manjanathaiah, İstanbul Univ. Fen Fak. Mec. Ser. A **26** (1961), 9–13; MR **26** #5163], or if $n(r)$ is slowly oscillating.

Hellerstein, S.; Rubel, L. A. 3636

Subfields that are algebraically closed in the field of all meromorphic functions.

J. Analyse Math. **12** (1964), 105–111.

Suppose that the functions $f(z), f_0(z), \cdots, f_l(z)$ are meromorphic in $|z| < R \leq \infty$ and satisfy the identity

$$\sum_{j=0}^{n} f_j(z) f(z)^j = 0. \qquad (1)$$

The authors prove by induction that, with the usual notation of Nevanlinna theory,

$$T\left(r,\ \sum_{j=0}^{K} f_j(z)f(z)^j\right) = T\left[r, f_0(z)+f(z)\sum_{j=1}^{K-1} f_j(z)f(z)^{j-1}\right]$$
$$\leq \sum_{j=0}^{K} T[r, f_j]+KT[r, f]+K\log 2,$$
$$K = 0, 1, \cdots, n-1.$$

Hence (1) implies

$$T(r, f) \leq \sum_{j=0}^{n} T(r, f_j)+O(1) \quad \text{as } r \to R.$$

Thus the growth of $f(z)$—as given for instance by the order and type for functions in the plane—cannot exceed the maximal growth of the $f_j(z)$. If $f(z)$ and the $f_j(z)$ are regular, the authors use the inequality

$$T(r, f) \leq \log^+ M(r, f) \leq \frac{R+r}{R-r}\, T(R, f), \qquad 0 < r < R,$$

to obtain somewhat weaker results for the growth defined in terms of $\log M(r, f)$ instead of $T(r, f)$.

Collingwood, E. F.; Piranian, George 3637

Tsuji functions with segments of Julia.

Math. Z. **84** (1964), 246–253.

A meromorphic function w in the open unit disk D is said to be a Tsuji function if it maps the circles $\{z : |z| = r\}$, $0<r<1$, onto curves whose spherical lengths form a bounded set. A rectilinear segment S lying in D except for one endpoint $e^{i\theta}$ on the unit circle C is called a segment of Julia for w provided, in each open triangle in D having one vertex at $e^{i\theta}$ and meeting S, the function w assumes all values on the Riemann sphere except possibly two. A point $e^{i\theta}$ is a Julia point for w if each rectilinear segment lying in D except for one endpoint at $e^{i\theta}$ is a segment of Julia for w.

In a review [MR **22** #11131] of a paper by M. Tsuji [Comment. Math. Univ. St. Paul. 8 (1960), 53–55], W. Seidel asked whether a Tsuji function can have segments of Julia. The present paper displays several relevant examples, all of which are motivated by the results in Tsuji's paper. Theorem 1: There exists a Tsuji function for which each point $e^{i\theta}$ is a Julia point. Theorem 3: If E is a set of measure 0 on C, then there exists a Tsuji function of bounded characteristic for which every point of E is a Julia point. Theorem 5: There exist holomorphic Tsuji functions with segments of Julia. The paper closes with three conjectures.

{Reviewer's comments: In the Lemma on p. 247, "$z_n \to 1$" should read "$|z_n| \to 1$". Also, the estimate on line 9 of p. 248, as well as subsequent dependent estimates, needs to be altered slightly.}

Storvick, D. A. 3638

Radial limits of quasiconformal functions.

Nagoya Math. J. **23** (1963), 199–206.

It is known from the work of Beurling and Ahlfors on the boundary correspondence under a quasiconformal mapping that for quasiconformal functions the analogue of Fatou's theorem is false. By imposing an additional restriction on the dilatation quotient $Q[f(z)]$ of the quasiconformal function $f(z)$, the author is able to prove such an analogue: If $w=f(z)$ is a bounded K-quasiconformal function in the upper half-plane, $\operatorname{Im}(z)>0$, $|f(z)| \leq M$, and if there exists an essentially bounded measurable function $\kappa(x)$ such that for almost all $z=x+iy$,

$$Q[f(z)]-1 \leq \kappa(x)\cdot y,$$

then the limit, $\lim_{y\to 0} f(x+iy)=f^*(x)$, exists for all real numbers x except possibly for an exceptional set of linear measure zero.

Also proved is an analogue of a theorem of Privalov on bounded analytic functions: Let $w=f(z)$ be a quasiconformal function defined in $|z| \leq 1$. If the set of points $e^{i\theta}$ on $|z|=1$ at which the complement of the radial cluster set is non-empty is of second category on some arc A of $|z|=1$, then, unless $f(z)$ is identically constant, the set of radial limit values of $f(z)$ on the arc A is of positive linear measure.

Storvick, D. A. 3639

A localization principle for a class of analytic functions.

Nagoya Math. J. **23** (1963), 207–212.

An analytic function of modulus ≤ 1 on the open unit disk is said to belong to the class U^* provided that its Fatou radial limits exist and are of modulus one save for a set of zero logarithmic capacity on $\{|z|=1\}$. The following theorem is proved. Let f be a non-constant member of U^*. Let $\{|z-a|<\rho\} \subset \{|z|<1\}$. Let G denote a component of $f^{-1}(\{|z-a|<\rho\})$. Let φ denote a univalent conformal map of the unit disk onto G. If for every w, $|w|=1$, $\operatorname{cap}\{e^{i\theta} \mid f^*(e^{i\theta})=w\}=0$, then $F=(1/\rho)(f\circ\varphi-a) \in U^*$ and, for every W, $|W|=1$, $\operatorname{cap}\{e^{i\theta} \mid F^*(e^{i\theta})=W\}=0$. Here the asterisk refers to the Fatou radial limit. The proof makes use of a theorem of Pfluger [Comment. Math. Helv. **29** (1955), 120–131, cf. p. 122; MR **16**, 810].

M. H. Heins (Urbana, Ill.)

Meier, Kurt 3640

Über die Randwerte der meromorphen Funktionen.

Math. Ann. **142** (1960/61), 328–344.

Let $f(z)$ be meromorphic in $G : \{\operatorname{Im} z>0\}$, $z=x+iy$, and let I be some finite interval on the x-axis. We denote by $s(\varphi, x)$ the set $\{\arg(z-x)=\varphi\}$, by $w(\alpha, \beta, x)$ the set $\{\alpha<\arg(z-x)<\beta\}$, $0<\varphi<\pi$, $0<\alpha<\beta<\pi$. Let G' be some subset of G for which the point $z=x$ is a limit point. The cluster set of $f(z)$ as $z\to x$, $z \in G'$, will be denoted by $H(G', x)$. Let $H_x=H(G, x)$, $S_x(\varphi)=H(s(\varphi, x), x)$, $W_x(\alpha, \beta)=H(w(\alpha, \beta, x), x)$, $\Pi_x=\bigcap S_x(\varphi)$ for $0<\varphi<\pi$, $\Lambda_x=\bigcap W_x(\alpha, \beta)$ for $0<\alpha<\beta<\pi$. The extended w-plane will be denoted by Ω. Let A be the set of those $x \in I$ for which $\Omega \setminus \Lambda_x$ consists of no more than two points, B the set of those $x \in I$ for which $\Pi_x \cup \Lambda_x=\Omega$, C the set of those $x \in I$ for which all $w(\alpha, \beta, x)$, $0<\alpha<\beta<\pi$, consists of one point, D the set of those $x \in I$ for which $\Omega \setminus H_x$ is non-empty with $\Pi_x=H_x$, F the set of those $x \in I$ for which there exists not more than one ray $s(\varphi, x)$ on which $f(z)$ is bounded.

The basic results of the paper are the following: (1) $\operatorname{mes}\{I \setminus (A \cup B \cup C)\}=0$; (2) $I \setminus (A \cup B \cup C)$ is a set of first category. If $f(z)$ is regular in G, then (3) $\operatorname{mes}\{I \setminus (C \cup F)\}=0$, and (4) $I \setminus \{D \cup F\}$ is a set of first category.

The result (1) sharpens a theorem of A. I. Plessner [see,

for example, I. I. Privalov, *Boundary properties of analytic functions*, second edition (Russian), GITTL, Moscow, 1950; MR 13, 926; German transl., VEB Deutscher Verlag, Berlin, 1956; MR 18, 727].

The proof depends in an essential way on this theorem.

A. A. Gol'dberg (RŽMat 1961 #9 B70)

Bagemihl, Frederick 3641

Analytic continuation and the Schwarz reflection principle.

Proc. Nat. Acad. Sci. U.S.A. **51** (1964), 378–380.

Let I be an open interval on the real axis, G_1 be a region in the upper half-plane, and G_2 be a region in the lower half-plane, such that I is a free boundary arc of both G_1 and G_2. Let $f(z)=f_j(z)$, where $f_j(z)$ is holomorphic in G_j for $j=1, 2$.

In extending the work of Carleman [*L'intégrale de Fourier et questions qui s'y rattachent*, Almqvist & Wiksells, Uppsala, 1944; MR 7, 248], Wolf [Duke Math. J. **14** (1947), 877–887; MR **9**, 420], and Meier [Comment. Math. Helv. **24** (1950), 238–259; MR **12**, 490], the author proves the following theorem. Let S be a subset of I of Lebesgue measure zero and first Baire category. For every $t\in I-S$, let λ_t^1 be an arc in G_1 at t, λ_t^2 be an arc in G_2 at t, ω_t be a finite complex number, and put $\varphi(t)=\omega_t$ $(t\in I-S)$. Suppose that

(a) $\lim_{\substack{z\to t\\ z\in\lambda_t^1}} f_1(z) = \lim_{\substack{z\to t\\ z\in\lambda_t^2}} = \omega_t$ for every $t\in I-S$;

(b) φ is bounded in some neighborhood of every point of $I-S$, (c) $\bar{A}_\infty\cap(I-S)=\varnothing$, where $\bar{A}_\infty$ is the closure of the set of points of I at which at least one of the functions f_1, f_2 has ∞ as an asymptotic value. Then f is holomorphic at each point of an everywhere dense subset of I.

Doob, J. L. 3642

One-sided cluster-value theorems.

Proc. London Math. Soc. (3) **13** (1963), 461–470.

This paper is concerned with the relationship between the cluster values and range of a function f, meromorphic in $|z|<1$, at a point on $|z|=1$ ($z=1$, say) for approach from the interior of the disk and approach on the boundary from one side. Let C, B, R, denote the cluster-set, boundary cluster-set and range of $f(z)$ at $z=1$. The classical Gross-Iversen theorem [Noshiro, *Cluster sets*, p. 4 et seq., Springer, Berlin, 1960; MR **24** #A3295] says that (i) $B\supset\partial C$; (ii) Each point of $C\cap\mathscr{C}B\cap\mathscr{C}R$ is an asymptotic value of f at 1; (iii) $C\cap\mathscr{C}B\cap\mathscr{C}R$ contains at most two points, and will contain two points only if R is the extended plane less these two points.

The author's main theorem, Theorem G, is a generalization of this theorem for one-sided boundary approach, involving only the boundary cluster set from one side. For example, (i) above becomes $B_s\supset\partial C(0)$, where B_s is the boundary cluster set at 1 from the south and $C(0)$ is the set of tangential-from-below cluster values. Similarly (ii) and (iii) are generalized. From this elegant theorem the author deduces the classical Gross cluster-value theorem [Gross, Math. Z. **3** (1919), 43–64] and a refinement of it. Several interesting generalizations and consequences of Theorem G are also given.

Some properties of analytic functions of class H_p'. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 528–531.

The class H_p' $(p>0)$ consists of the functions f analytic in $|z|<1$ for which $H_p'(f)$, the integral of $|f(z)|^p$ over the unit disk, is finite. The author gives a number of theorems involving H_p'. (1) If $f'\in H_1'$, then $f\in H_1$ (the converse is false). (2) If f is in every H_p' for $p<1$, then so is f'. (3) If $0<\delta<1$, there exists $f_0\in H_\delta$ for which $f_0\notin H_{\delta+\varepsilon}$ for any $\varepsilon>0$, but f_0' is in every H_p', $p<1$. (4) If $f\in H_p'$ but $f\notin H'_{p+\varepsilon}$ for any $\varepsilon>0$, and if $\max|f(z)|=O(\varphi(r))$, where φ is continuous and nondecreasing, then $\int_0^1\varphi^q(r)\,dr=\infty$ for $q>p$. (5) If $f\in H_p$, $p<1$, then $f'\in H_q'$ for $q<2p/(p+1)$. (6) If $f\in H_p'$ and a_k are its zeros, then $\sum(1-|a_k|)^{1+\varepsilon}<\infty$ for every $\varepsilon>0$ (not necessarily for $\varepsilon=0$). (7) If $H_1'(f)=2\pi$ and a_n are the Maclaurin coefficients of f, then $|a_n|\le n+2$; there is equality for $f(z)=e^{i\alpha}(n+2)z^n$.

Mikhail, M. N. 3644

The effectiveness of the inverse and the product of basic sets of polynomials.

Proc. Math. Phys. Soc. U.A.R. (Egypt) No. **25** (1961), 43–48 (1964).

A basic set of polynomials $\{p_n(z)\}$ is a sequence for which the equations $z^n=\sum\pi_{n,k}p_k(z)$, $n=0, 1, \cdots$ admit a unique solution. If $f(z)$ is analytic in $|z|<R$ with Taylor series $\sum a_nz^n$, and if the formal rearrangement $\sum b_np_n(z)$ converges uniformly on closed subsets of $|z|<R$, then $\{p_n(z)\}$ is said to be effective in $|z|<R$. The sequence $\{q_n(z)\}$, $q_n(z)=\sum\pi_{n,k}z^k$, is said to be the inverse set of $\{p_n(z)\}$. Let $\{r_n(z)\}$ be a basic set, with $r_n(z)=\sum r_{n,k}z^k$. The sequence $\{u_n(z)\}$, $u_n(z)=\sum r_{n,k}p_k(z)$, is a basic set; it is also denoted by $\{r_n(z)\}\cdot\{p_n(z)\}$ and is called the product of the two sets taken in that order.

The author claims to generalize the known conditions concerning circles in which basic sets, their inverse sets, and product sets of inverse sets are effective. A monograph by J. M. Whittaker [*Sur les séries de base de polynômes quelconques*, Gauthier-Villars, Paris, 1949; MR **11**, 344] lays the foundation for this subject and should definitely be consulted since the extremely narrow focus of this article does not permit it to communicate the interest of the subject matter.

Mikhail, M. N. 3645

The effectiveness of basic sets of polynomials in general domains. I.

Proc. Math. Phys. Soc. U.A.R. (Egypt) No. **25** (1961), 49–54 (1964).

A function analytic inside a simple analytic curve C with interior D has an expansion $\sum a_nf_n(z)$, where $f_n(z)$ is the nth Faber polynomial associated with C. If a sequence of polynomials $\{u_n(z)\}$ is such that $f_n(z)=\sum\pi_{n,k}u_k(z)$ admits a unique solution, then it is called a basic set associated with D. If the series $\sum b_nu_n(z)$ obtained by formal rearrangement of the Faber expansion converges uniformly in closed subsets of D, the set is said to be effective in D. The author establishes criteria for the effectiveness of basic sets associated with D which generalize known criteria. He then investigates inverse sets and product sets which can also be defined in this context [see #3644].

The effectiveness of the inverse and the product sets of basic sets of polynomials in a general region. II.

Proc. Math. Phys. Soc. U.A.R. (Egypt) No. 25 (1961), 55–57 (1964).

This paper continues the study of the effectiveness of basic sets associated with non-circular domains [see #3645], and the effectiveness of inverse sets of basic sets, and of product sets of basic sets. *J. L. Ullman* (Ann Arbor, Mich.)

Dineen, B. L. 3647

The deviation of analytic functions from the mean arithmetic partial sums of the Faber series. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 250–253.

Let ω be a non-decreasing function defined for $t \geq 0$, satisfying $\omega(0)=0$, $\omega(t_1+t_2) \leq M[\omega(t_1)+\omega(t_2)]$, M being a constant, let A_ω be the class of functions f defined in $[-1, 1]$ such that for each n there exists an algebraic polynomial P_n of degree n satisfying

$$|f(x)-P_n(x)| \leq \omega(n^{-1}(\sqrt{(1+x^2)}+n^{-1})).$$

Denote by $T_0(x)=\pi^{-1/2}$, $T_k(x)=(2/\pi)^{-1/2}\cos(k \operatorname{arc}\cos x)$, the sequence of Čebyšev polynomials, let

$$C_k = \int_{-1}^{1} f(t)T_k(t)(1-t^2)^{-1/2}\,dt$$

be the Fourier coefficients of f, and let

$$\sigma_n(f,x) = \sum_{k=0}^{n-1}(1-k/n)C_kT_k(x).$$

Theorem: If $f \in A_\omega$ and $x \in [-1, 1]$, then

$$|f(x)-\sigma_n(f,x)| \leq (C/n)\sum_{k=1}^{n}\omega(k^{-1}(\sqrt{(1-x^2)}+k^{-1})),$$

C being a universal constant. If f is merely continuous on $[-1, 1]$, then

$$|f(x)-\sigma_n(f,x)| \leq n^{-1}\sum_{k=1}^{n}[\omega_1(f,k^{-2})+\omega_2(f,k^{-1}\sqrt{(1-x^2)})],$$

ω_1 and ω_2 denoting the moduli of continuity of the first and the second order.

Let G be a simply connected region in the complex plane, with boundary C, let the function φ map G conformally onto the region $|w|>R$, along with the conditions $\varphi(\infty)=\infty$, $\lim_{z\to\infty} z^{-1}\varphi(z)=1$, ψ being the inverse function of φ; let $\Phi_n(z)$ be the corresponding nth Faber polynomial. If f is analytic in G and continuous on $\bar{G}$, let $a_k=(2\pi i)^{-1}\int_{|w|=R} f(\psi(w))w^{-k-1}\,dw$ be the kth Fourier coefficient with respect to the system $\{\Phi_n\}$, and let $\sigma_n(f,\Phi_n,z)=\sum_{k=0}^{n-1}(1-k/n)a_k\Phi_k(z)$ be the nth Fejér sum. If the boundary of G is sufficiently smooth and if f satisfies certain additional conditions at the angular points of the boundary (not to be stated here explicitly), then

$$|f(z)-\sigma_n(f,\Phi_n,z)| \leq (C_1/n)\sum_{k=1}^{n}\omega_1(f,\rho_{1+1/k}(z)),$$

$\rho_{1+1/k}(z)$ denoting the distance of z from the set

$$\{\zeta: |\varphi(\zeta)| = (1+1/k)R\}.$$

Zverovič, È. I. 3649

Boundary-value problems with shift on abstract Riemann surfaces. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 26–29.

The author examines several boundary-value problems of displacement on a Riemann surface R containing a domain D^+ bounded by a smooth closed contour L with exterior D^-. A typical problem is that of finding two sectionally analytic functions φ^+, φ^-, on D^+, D^-, respectively, extensible to L, and obeying on L the relation

$$\varphi^+[\alpha_+(Q)] = G(Q)\varphi^-(Q)+g(Q)$$

or

$$\varphi^+[Q] = G(Q)\overline{\varphi^-[\alpha_-(Q)]}+g(Q)$$

with α_+, α_- homeomorphisms of L onto itself preserving and reversing orientation, respectively, and $G \neq 0$ and g are Hölder-continuous functions on L.

A method is proposed for reducing these problems to Riemann problems of the form

$$\varphi^+(Q') = G(Q')\varphi^-(Q')+g(Q')$$

on a curve L' in a Riemann surface R' obtained from R by appropriate transformations based on ideas due to Bojarski [I. N. Vekua, *Generalized analytic functions* (Russian), Chapter IV, Fizmatgiz, Moscow, 1959; MR **21** #7288]; several interesting questions are discussed, and estimates on the number of solutions are given in some cases.

The paper augments the work of several authors including W. Koppelman [Comm. Pure Appl. Math. **12** (1959), 13–35; MR **26** #3916] and E. Hasabov [Izv. Vysš. Učebn. Zaved. Matematika **1963**, no. 2 (33), 124–133; MR **27** #3811]. *A. D. Solomon* (New York)

A generalization of the Riemann-Schwarz symmetry principle and its applications. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1051–1053.

The author states without proof the following generalization of the Riemann-Schwarz symmetry principle for analytic functions: Let $F(z)$ be holomorphic in the domain D and continuous in $\bar{D}$. If the boundary of D contains a segment l of a straight line or a circle on which $\operatorname{Re}[\lambda(t)F(t)]$ vanishes, where $\lambda(t)$ $(t \in l)$ is a given non-vanishing Hölder-continuous function, then there exists a holomorphic function $\chi(z)$, defined in D, for which $\chi(z)F(z)$ is analytically continuable beyond l. In particular, if one denotes the reflection of D with respect to l by D^* and the reflection of a point $z \in D$ by z_1, then the function

$$\Phi(z) = \chi(z)F(z), \qquad z \in D,$$
$$= -\overline{\chi(z_1)}\overline{F(z_1)}, \qquad z \in D^*,$$

is holomorphic in $D+D^*+l$. The function $\chi(z)$ is obtained as a solution of the boundary problem

$$\chi^+(t) = \frac{\lambda(t)}{\overline{\lambda(t)}}\chi^-(t), \qquad t \in l,$$

where $\chi^-(t) = \overline{\chi^+(t)}$.

This generalized symmetry principle is then employed to solve Riemann-Hilbert boundary problems for special domains. Thus, for the case of a semi-circle he solves the problem of determining a function $F(z)$ holomorphic in $D(|z|<1, y>0)$, continuous in $\bar{D}$ (with the possible exception of $z = \pm 1$, where it is assumed that

$$F(z) \leq \text{const}/|z \mp 1|^\alpha, \qquad \alpha < 1,$$

and satisfying the boundary conditions

$$\operatorname{Re}[\lambda(t)F(t)] = \varphi(t) \quad \text{for} \quad t \in [|t| = 1, y > 0],$$
$$\operatorname{Re}[\mu(x)F(x)] = \psi(x) \quad \text{for} \quad -1 \leq x \leq 1,$$

where $\lambda(t)$, $\mu(x)$ are given functions, non-vanishing and Hölder-continuous. *J. F. Heyda* (King of Prussia, Pa.)

Titus, Charles J. 3652

The combinatorial topology of analytic functions on the boundary of a disk.

Acta Math. **106** (1961), 45–64.

Soit D un domaine du plan complexe, qui soit l'intérieur d'une courbe de Jordan C; une application de C dans le plan complexe est appelée frontière intérieure si elle est la restriction à C d'une application, définie et continue dans $\bar{D}$, dont la restriction à D est intérieure et conserve l'orientation; une application est dite intérieure si l'image d'un ouvert est un ouvert, et si l'image réciproque de tout point est totalement discontinue. L'auteur résout, du point de vue de la topologie combinatoire, le problème suivant: Trouver une condition nécessaire et suffisante pour qu'une représentation normale d'une courbe fermée orientée soit une frontière intérieure. La notion de représentation normale a été introduite par H. Whitney [Compositio Math. **4** (1937), 276–284]. La solution d'un problème posé par E. Picard [*Traité d'analyse*, Tome II, troisième édition revue et augmentée, p. 313, Gauthier-Villars, Paris, 1926] est un corollaire de celle du problème ci-dessus.

Ullman, J. L.; Titus, C. J. 3653

An integral inequality with applications to harmonic mappings.

Michigan Math. J. **10** (1963), 181–192.

The integral inequality referred to is the following. Let $h(\theta)$ be continuous and non-decreasing on $[0, \pi]$ with $h(0) = 0$ and $h(\pi) = \pi$. Then $\int_0^\pi \exp[i(h(\theta)-\theta)]\,d\theta$ has modulus greater than 2, and this result is the best possible. Let u and v be harmonic in the open unit disk and continuous on its closure, and let $H = u+iv$ map the closed unit disk onto itself in a one-to-one and sense-preserving manner with the origin and the point 1 mapping into themselves. Let $M = u_x^2 + u_y^2 + v_x^2 + v_y^2$ and $J = u_xv_y - u_yv_x$, all derivatives being computed at the origin. The quantity $M+2J$ is related to the distortion of the mapping at the origin. Let $\lambda = \inf(M+2J)$, the infimum being taken over all mappings of the class described. It is conjectured that $\lambda = 16/\pi^2$, and the corresponding result is proved in the case in which the class of mappings is restricted to those for which $H(-z) = -H(z)$, i.e., odd mappings.

Konforme Abbildungen der hyperbolisch-euklidischen Ebene durch hyperkomplexe Funktionen.

Math. Z. **84** (1964), 254–262.

Hyperkomplexe Zahlen $x+jy$ und Funktionen $f(z) = u(x, y) + jv(x, y)$ $(j^2 = 1)$ werden betrachtet. Nach einer Zusammenfassung früherer Ergebnisse des Verfassers [Jber. Deutsch. Math.-Verein. **61** (1958), Abt. 1, 32–56; MR **21** #3536] wird das lokale Verhalten der Abbildung $w = f(z)$ in der Umgebung einer Stelle z_0 studiert, an der die $n-1$ ersten Ableitungen von $f(z)$ verschwinden, nicht jedoch die n-te, und wo ferner $(\partial^n u/\partial x^n)^2 - (\partial^n v/\partial x^n)^2 \neq 0$ ist. Der Fall eines nicht schlichten Bildgebiets führt zur Einführung Riemannscher Flächen, die mehrfach gefaltete Ebenen sein können. Ist $F(x, y)$ eine Lösung der Wellengleichung, so können Krümmungseigenschaften der Fläche $\zeta = F(x, y)$ mit der Abbildung $w = f(z)$ $(u = F_y, v = F_x)$ in Beziehung gebracht werden. *D. On bi-analytic functions with non-isolated a-points. (Russian. Armenian summary)

Izv. Akad. Nauk Armjan. SSR Ser. Fiz.-Mat. Nauk **17** (1964), no. 3, 7–19.

A bi-analytic function is a function of the form $f(z) = \phi(z) + \bar{z}\psi(z)$, where ϕ and ψ are analytic. Simple examples (e.g., $z+\bar{z}$) show that the solutions of $f(z) = a$, $a = \text{const}$, need not be isolated, further examples being provided by

the whole class of degenerate bi-analytic functions determined completely by the author [same Izv. **17** (1964), no. 2, 9–15; MR **29** #1345]. The author finds a necessary and sufficient condition for $f(z)$ to have a non-isolated a-point at z_0, and this enables him to construct non-degenerate examples. He obtains further results in the cases when ϕ, ψ are meromorphic or entire functions.

Stoddart, A. W. J. 3660

The shape of level surfaces of harmonic functions in three dimensions.

Michigan Math. J. **11** (1964), 225–229.

Let $g(P)$ be the Green's function of a region D in E_3, with pole at the origin 0. It is a well-known result of J. J. Gergen [Amer. J. Math. **53** (1931), 746–752] that if D is star-shaped relative to 0, then the regions $D_k = \{P : g(P) > k\}$ are star-shaped relative to 0. Similarly, R. M. Gabriel [J. London Math. Soc. **30** (1955), 388–401; MR **17**, 358] has shown that if D is convex, then the regions D_k are also convex.

The author now obtains corresponding results for harmonic functions, replacing the pole at the origin by a continuum, which is star-shaped relative to the origin or convex in the respective cases, and on which the function is constant.

The problem of the inclined derivative with polynomial coefficients. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1273–1275.

On étudie le problème de la dérivée inclinée avec des coefficients polynômiaux sur la frontière S du domaine D

$$P(y) \operatorname{grad} U(y) = f(y), \qquad y = (y_1, y_2, \cdots, y_n) \in S,$$

pour la fonction harmonique régulière $U(x)$,

$$x = (x_1, x_2, \cdots, x_n),$$

dans l'espace E_n. La fonction continue $f(y)$ est donnée, $P=(p_1, p_2, \cdots, p_n)$ est un vecteur polynômial donné de variables $y_1, y_2, \cdots, y_n$ et $\operatorname{grad} U(y)=\lim_{x\to y} \operatorname{grad} U(x)$. Des résultats intéressants sont énoncés surtout pour les domaines sphériques. *P. P. Teodorescu* (Bucharest)

Dynkin, E. B. 3663

Non-negative solutions of a boundary-value problem with inclined derivative. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1028–1030.

Let D be the interior of a smooth Jordan plane curve C and let $v(\cdot)$ be a smooth vector field on C, tangent to C at finitely many points. Let Γ be the set of points at which the projection of v on the internal normal to C changes sign. The author investigates the harmonic functions in D satisfying $\partial h/\partial v=0$ on $C-\Gamma$. These functions will be called "solutions" below. The set Γ is partitioned into Γ_- and Γ_+ according to the conduct of v near the points of Γ, and $\Gamma_+{}^0$ is a certain subset of Γ_+. If Γ_+ is empty, there are no non-constant non-negative solutions. Otherwise, every such solution has the form

$$(*)\qquad h=\sum_{\Gamma_-\cup\Gamma_+{}^0} a_e u_e+\sum_{\Gamma_+}(c_e{}^+p_e{}^+ + c_e{}^-p_e{}^-),$$

where $a_e, c_e{}^+, c_e{}^-$ are non-negative constants and $u_e, p_e{}^+, p_e{}^-$ are special solutions. For D a disk the special solutions are characterized precisely. A Martin boundary is defined (and described in detail) having the usual properties: each point of the Martin boundary is identified with a non-negative solution, certain (in this case finitely many) of these solutions are minimal, and every positive solution is a linear combination of minimal solutions. The minimal solutions are the special solutions of the representation (*). The Green's function of the problem is constructed. The probability interpretation of the problem, going back to Maljutov [same Dokl. **156** (1964), 1285–1287; MR **29** #2867] is given. Briefly, the corresponding stochastic process is a Brownian motion reflected at C in the direction v, and stopped when it hits Γ. *J. L. Doob* (Urbana, Ill.)

Zolin, A. F. 3664

Solution of boundary problems for the Laplace equation by an interpolation method. (Russian)

Issled. po Mat. Analizu i Mehanike v Uzbekistane, pp. 133–152. *Izdat. Akad. Nauk Uzbek. SSR, Tashkent*, 1960.

In this paper the author discusses the approximation by harmonic polynomials of the solutions of the Dirichlet and Neumann problems for the Laplace equation in circular and elliptical domains. The approximating polynomials in polar form are constructed by interpolating on the boundary. In the case of circular domains it is interpolation by trigonometric polynomials. For a domain bounded by an ellipse the interpolating functions are called "generalized" trigonometric polynomials. They are linear combinations of functions which constitute a so-called system of Markov (Definition 2).

The Dirichlet problem is considered first. For a circular domain (radius R), take as nodes of interpolation the equidistributed points of the circumference that correspond to the polar angles $\theta_i=2\pi i/(2n+1)$, $i=0, 1, \cdots, 2n$. The associated harmonic polynomial is denoted by $S_n(r, \theta)$. It is known from the theory of interpolation by trigonometric polynomials that for a boundary function satisfying a Dini-Lipschitz condition the sequence of interpolating polynomials $\{S_n(R, \theta)\}$ will converge uniformly to it. Thus the sequence of harmonic polynomials $\{S_n(r, \theta)\}$ will converge uniformly to the solution in the whole closed domain. Moreover, it is shown directly that the sequence $\{S_n(r, \theta)\}$ converges at interior points to the Poisson integral where the boundary function is, say, only continuous. For an elliptical domain consider the simple orientation-preserving affine stretching map that carries the unit circle into the ellipse. As nodes of interpolation on the bounding ellipse the images of the equi-distributed points on the circle as described above are chosen. Then it is shown that the corresponding sequence of harmonic polynomials will converge uniformly in the whole closed domain for a Lipschitz continuous boundary function. Furthermore, for a merely continuous boundary function the sequence of interpolating "generalized" polynomials converges in the mean square, and the associated sequence of harmonic polynomials converges uniformly in closed interior subsets of the domain. In addition, relative to a continuous boundary function, there is a rule for selecting the nodes of interpolation whereby the resulting interpolating sequence will be uniformly convergent. It is an implicit and hence non-constructive selection principle.

The last part of the paper is devoted to the Neumann problem. For this problem on an elliptical domain a conformal map is used, as opposed to the affine map referred to above. *R. K. Juberg* (Minneapolis, Minn.)

On a compactification of Green spaces. Dirichlet problem and theorems of Riesz type.

J. Math. Kyoto Univ. **1** (1961/62), 385–402.

On considère, dans un espace de Green R, une famille $\mathscr{C}$ de fonctions bornées continues à chacune desquelles correspond une fonction harmonique bornée dans R telle que la différence ait une pseudo-limite nulle en presque tout point de la frontière de Martin de R. Avec la norme du suprémum, $\mathscr{C}$ forme une algèbre normée dont l'espace des idéaux maximaux est un compact (non métrisable) R^* où R est ouvert dense, et de frontière $\Delta^*=R^*-R$, applicable continûment sur la frontière de Martin de R. La "frontière harmonique" de R est un sous-compact $\Delta_1{}^*$ de Δ^*. Toute $f\in\mathscr{C}$ se prolonge continûment sur R^*, de même toute fonction surharmonique positive continue dans R. On résoud le problème de Dirichlet pour R et frontière $\Delta_1{}^*$, et l'on donne diverses applications, dont un théorème du type de Riesz pour plusieurs variables complexes. *L. Lumer-Naim* (Grenoble)

Ohtsuka, Makoto 3666

Extremal length of families of parallel segments.

J. Sci. Hiroshima Univ. Ser. A-I Math. **28** (1964), 39–51.

The definition of the extremal length $\lambda(\Gamma)$ of a family Γ of curves c in the plane [Ahlfors and Beurling, Acta Math. **83** (1950), 101–129; MR **12**, 171] is here applied to a family Γ of collections c of open segments: each c consists of mutually disjoint open segments on one vertical line, and two different collections c and c' are supposed to be disjoint. Let $l(c)$ be the total length of c and χ_c the characteristic function of c in R^2. It is shown that if $\sum_{c\in\Gamma} l(c)\chi_c$ is

Lebesgue measurable in R^2 and $l(c) < \infty$ for each $c \in \Gamma$, then $1/\lambda(\Gamma) = M(\Gamma) = \int (\sum_{c \in \Gamma_x} l^{-1}(c))\, dx$. The case where $l(c)$ might be infinite and the "non-measurable" case are then discussed. Further, a family Γ' of collections c' of curves is considered such that each $c' \in \Gamma'$ intersects each $c \in \Gamma$; under certain general conditions it is proved that $\lambda(\Gamma) \cdot \lambda(\Gamma') \geq 1$. *J. Hersch* (Zürich)

Ohtsuka, Makoto 3667

On weak and unstable components.

J. Sci. Hiroshima Univ. Ser. A-I Math. **28** (1964), 53–58.

Extending a characterization due to M. Jurchescu [Pacific J. Math. 8 (1958), 791–809; MR **21** #2047], the author defines, by means of extremal length, the weakness and the instability of a point C as a component of a bounded set E in the plane. Let D be a disk containing E; C is called a weak component of E if the family Γ of closed curves around C in $D-E$ has extremal length $\lambda(\Gamma) = 0$; if $\lambda(\Gamma) > 0$, C is called an unstable component of E. Using this definition and some results of #3666 above, sufficient conditions are given for the weakness, respectively, for the instability of the point $(0, 0)$ with respect to a set of vertical segments in the strip $0 \leq x < 1$. The conditions thus obtained extend some theorems of T. Akaza and K. Oikawa [Nagoya Math. J. 18 (1961), 165–170; MR **24** #A1387]. *J. Hersch* (Zürich)

Fonctions entières (n variables) et fonctions plurisousharmoniques d'ordre fini dans C^n.

J. Analyse Math. **12** (1964), 365–407.

An elegant, new and constructive solution of the Cousin-II problem for entire divisors of finite order is given. Cousin's theorem establishes only the existence of a solution. H. Kneser [S.-B. Preuss. Akad. Wiss. Phys.-Math. Kl. **1936**, 446–462] gave a constructive solution for entire divisors of finite order in $\mathbf{C}^2$. His methods fail in $\mathbf{C}^n$. Nevertheless, the Kneser integral represents the logarithm of a solution also in the case of infinite order [the reviewer, Math. Z. 57 (1953), 211–237; MR **14**, 970]. However, the proof required the existence of a solution, and the Kneser integral only converges in a neighborhood of the origin. This paper avoids these disadvantages.

For $n > 1$, define $h_n(a, z) = |a-z|^{2-2n}$ for a, z in $\mathbf{C}^n$. For $a \neq 0$, develop h_n at zero into a series of polynomials P_ν, where P_ν is homogeneous in z, $\bar{z}$ and has degree ν. Then $e_n(a, z, q) = -h_n(a, z) + \sum_{\nu=1}^{q} P_\nu(a, z)$ is harmonic for $z \in \mathbf{C}^n - \{a\}$.

Let W be an entire divisor in $\mathbf{C}^n$, whose support $|W|$ does not contain the origin. Let $W(a)$ be the multiplicity of W at a. Let β_{n-1} be the volume element on $|W|$. Then $\sigma(t) = \int_{|W| \cap B(t)} W(a)\beta_{n-1}(a)$ is the volume of W in the ball $B(t) = \{z \mid |z| \leq t\}$. The function $\nu(t) = (n-1)!\pi^{-n+1}t^{2-2n}\sigma(t)$ increases monotonically. Suppose that

$$\operatorname{Ord} \nu = \limsup_{t \to \infty} \frac{\log \nu(t)}{\log t}$$

is finite. Let $q+1 > 0$ be the smallest integer such that $\int_0^\infty \nu(t)t^{-q-2}\, dt$ converges. Then

$$I_q(z) = \int_{|W|} W(a)e_n(a, z, q)\beta_{n-1}$$

converges and is harmonic on $\mathbf{C}^n - |W|$. Surprisingly, I_q is plurisubharmonic on $\mathbf{C}^n - |W|$. For, let W be represented by the Cousin distribution $\{U_j, f_j\}$. Then $H_j = I_q - \log|f_j|$ is harmonic on U_j. Define $A^{\mu,\nu} = I_{q z_\mu \bar{z}_\nu}$. Since $A^{\mu,\nu} = H_{j z_\mu \bar{z}_\nu}$ on U_j, the functions $A^{\mu,\nu}$ are harmonic on $\mathbf{C}^n$. A direct estimate shows that they are polynomials in z, $\bar{z}$ of at most degree $q-2$. By their definition, their partial derivatives of order $\leq q-2$ vanish. Hence $A^{\mu,\nu} \equiv 0$, and I_q is plurisubharmonic on $\mathbf{C}^n - |W|$. Now, $2\pi I_q = \log|F_0|$, where F_0 is entire with divisor W.

Obviously, the method is restricted to divisors of finite order. According to Hadamard's theorem, which was extended to several variables by H. Kneser [Jber. Deutsch. Math.-Verein. 48 (1938), 1–28], only one entire function F with divisor W exists such that $F(0) = 1$ and such that all partial derivatives of $\log F$ of order $\leq q$ vanish at 0. Hence this is the canonical function F_0 and the canonical function h as constructed by the reviewer [Math. Z. 57 (1953), 211–237; MR **14**, 970].

Since I_q exists on $\mathbf{C}^n - |W|$, the properties of F_0 can be read off directly and the classical results and methods of one variable carry over to several variables.

The results are stated and proved with the help of the theory of currents. However, both can be done without this theory. The use of currents does not only yield elegant proofs but extends to the construction of a plurisubharmonic function V of order λ such that $2i\partial_z\bar{\partial}_z V = \vartheta$, where ϑ is a given closed positive current of type $(1, 1)$ and of finite order λ.

The essential results of the paper were already published without proofs [C. R. Acad. Sci. Paris **237** (1953), 691–693; MR **15**, 415; ibid. **237** (1953), 865–867; MR **15**, 416; ibid. **237** (1953), 1379–1381; MR **16**, 123; Ann. Acad. Sci. Fenn. Ser. A I No. 250/21 (1958); MR **20** #2467].

Comparaison d'indicatrices de croissance pour des fonctions plurisousharmoniques ou entières d'ordre fini.

J. Analyse Math. **12** (1964), 409–418.

Recent results of P. Lelong [see the previous review #3668] permit one to extend methods and results of entire functions of one variable and finite order to plurisubharmonic functions of finite order. Some of these extensions are done in this paper. The only new element in several variables is the use of the well-known estimate (1) (Poisson inequality). The results are specialised to $V = \log|f|$, where f is an entire function of finite order. These specializations are either contained in Théorèmes 1′, 4′, 5′ or obtained trivially in Théorèmes 1′, 3′, or obtained as in one variable (Théorème 6′) from the reviewer's paper [Math. Z. 57 (1953), 211–237; MR **14**, 970] if one observes that the Nevanlinna characteristic $\lambda(\log^+ V, 0, r)$ differs from the Ahlfors-Shimizu-Weyl characteristic $T(r, r_0)$ only by a bounded function. In Proposition 1, Théorème 1 and Théorème 1′, it is not necessary to restrict p to a compact set. *W. Stoll* (Notre Dame, Ind.)

Stoll, Wilhelm 3670

The growth of the area of a transcendental analytic set. I, II.

Math. Ann. **156** (1964), 47–78; *ibid.* **156** (1964), 144–170.

The main result of this paper is the theorem that if M is a pure p-dimensional complex analytic subvariety of the space $\mathbf{C}^k$ of k complex variables, $0<p<k$, then M is algebraic if and only if the function $V(r)r^{-2p}$ is bounded, where $V(r)$ is the area of the intersection $M_r = M \cap \{z \in \mathbf{C}^k \,|\, |z| \leq r\}$ and is defined as the integral over M_r of a canonical differential form. More generally, let ζ be any continuous, positive definite, exterior differential form of bidegree (p, p) on the k-dimensional complex projective space $\mathbf{P}^k$, and let $j: \mathbf{C}^k \to \mathbf{P}^k$ be the analytic imbedding defined by $j(z_1, \cdots, z_k) = (1 : z_1 : \cdots : z_k)$; then M is algebraic if and only if $\int_M j^*(\zeta) < \infty$. The special case $p = k-1$ was treated earlier by Rutishauser [Acta Math. **83** (1950), 249–325; MR **12**, 90] and the author [Math. Z. **60** (1954), 287–304; MR **16**, 463], and the special case $p=1$ by the author [ibid. **81** (1963), 76–98; MR **29** #2430]. The proof, which is rather involved, is based upon an extension of the theory of value distribution of entire functions [cf. H. Weyl, *Meromorphic functions and analytic curves*, Princeton Univ. Press, Princeton, N.J., 1943; MR **5**, 94] to analytic varieties, following the lines of the author's work [Acta Math. **90** (1953), 1–115; MR **17**, 893; ibid. **92** (1954), 55–169; MR **17**, 894].

Mehrdeutige Funktionen zu gegebenen Divisoren auf einem Produktraum.

Math. Ann. **155** (1964), 35–52.

Soient X un espace analytique complexe (au sens de J. P. Serre), $\hat{X}$ le revêtement universel de X et D un diviseur de X. On dit que D est résoluble par une fonction multiforme s'il existe une fonction méromorphe sur $\hat{X}$ admettant pour diviseur l'image réciproque $\hat{D}$ de D par la projection canonique: $\hat{X} \to X$. On désigne par $\mathbf{O}$ le faisceau des germes de fonctions holomorphes. Soient X et Y deux espaces analytiques complexes tels que, sur X, il existe une intégrale de première espèce de périodes données. Soit D un diviseur de $X \times Y$ satisfaisant à: (1) D est résoluble sur $X \times Y$; (2) pour des points particuliers $\xi \in X$, $\eta \in Y$, les traces D_ξ et D_η de D sur les sous-espaces $\xi \times Y$ et $X \times \eta$ sont résolubles par des fonctions multiformes données g_ξ, f_η. Alors, il existe une solution de D dont les facteurs d'automorphie sont des fonctions simples des facteurs d'automorphie de g_ξ et f_η et d'une fonction holomorphe sur X qui dépend homomorphiquement des classes d'homologie rationnelles des éléments de $\pi_1(Y)$. La condition (1) est réalisée si $H^1(\widehat{X \times Y}, \mathbf{O}) = 0$. On obtient des théorèmes plus précis si on se borne aux fonctions automorphes multiplicatives [cf. K. Stein, Acta Math. **83** (1950), 165–196; MR **12**, 252] et aux fonctions théta [cf. G. de Rham et K. Kodaira, *Harmonic integrals*, Chapitre V, Inst. Advanced Study, Princeton, N.J., 1950; MR **12**, 279]. Un grand nombre de cas particuliers importants (par exemple, l'un des espaces considéré est de Stein ou est une variété kählérienne compacte) sont étudiés et les résultats de Stein (mémoire cité) généralisés. La technique utilise la cohomologie des groupes et des résultats antérieurs de l'auteur [Math. Ann. **148** (1962), 147–172; MR **26** #6442].

P. Dolbeault (Poitiers)

Norguet, François 3672

Sur la cohomologie des variétés analytiques complexes et sur le calcul des résidus.

C. R. Acad. Sci. Paris **258** (1964), 403–405.

Let X be a complex manifold, S a complex submanifold of codimension k. The author shows that every closed C^∞ form in $X-S$ is cohomologous to one having a certain type of amenable singularity on S. Specifically, a "local kernel" is defined to be a pair (U, K), U an open subset of X, K a differential form in $U-S$ given by

$$\left(\sum_{1\leq j\leq k} (s_j \bar{s}_j)\right)^{-k}\left(\bigwedge_{1\leq j\leq k} ds_j\right) \wedge \left[\sum_{1\leq h\leq k} (-1)^{h-1}\bar{s}_h\left(\bigwedge_{j\neq h} d\bar{s}_j\right)\right],$$

where s_j are holomorphic functions in U, $\bigwedge ds_j \neq 0$ in U, and $U \cap S$ is the common zero set in U of the functions s_j. A form φ, C^∞ in $X-S$, is called simple in X if there is a C^∞ form ψ on X and a family $\{(U_i, K_i)\}_{i\in I}$ of local kernels, with $\{U_i\}$ a covering of X, such that for all $i \in I$,

$$\varphi|U_i = K_i \wedge (\psi|U_i) + \theta_i, \qquad \text{where } \theta_i \text{ is } C^\infty \text{ in } U_i.$$

It is established that every C^∞ closed form in $X-S$ is cohomologous to a form simple in X. This result is used to study the "residue homomorphism" $r: H^q(X-S) \to H^{q-2k+1}(S)$ (see J. Leray [Bull. Soc. Math. France **87** (1959), 81–180; MR **23** #A3281] and the author [C. R. Acad. Sci. Paris **248** (1959), 2057–2059; MR **21** #5195]). The author shows that for cohomology classes h_1, h_2, h_3 of respective degrees p_1, p_2, p_3 of $X-S$, one has

$$(-1)^{p_1(p_3-1)} r(h_1) \cup r(h_2 \cup h_3) + (-1)^{p_2(p_1-1)} r(h_2) \cup r(h_3 \cup h_1) + (-1)^{p_3(p_2-1)} r(h_3) \cup r(h_1 \cup h_2) = 0.$$

A. Browder (Berkeley, Calif.)

Ônishi, Hidekazu 3673

Sur une extension du théorème de MM. H. Cartan et P. Thullen.

J. Math. Kyoto Univ. **3** (1963/64), 193–206.

The theorem of H. Cartan and P. Thullen [Math. Ann. **106** (1932), 617–647] is generalized to ramified coverings. Let $H(S)$ be the set of all holomorphic functions on the complex space S. If $\varnothing \neq M \subseteq S$ and $\varnothing \neq \mathfrak{F} \subseteq H(S)$, define $\|f\|_M = \sup\{f(x) \,|\, x \in M\}$ if $f \in H(S)$ and

$$\hat{M}(\mathfrak{F}) = \{x \,|\, |f(x)| \leq \|f\|_M \quad \text{for all } f \in \mathfrak{F}\}.$$

Now, let $\mathfrak{D}$ be a normal complex space. Let $\pi: \mathfrak{D} \to \mathbf{C}^n$ be an open holomorphic map such that $(\mathfrak{D}, \pi)$ is a Riemann domain in the sense of H. Grauert and R. Remmert [Math. Z. **67** (1957), 103–128; MR **19**, 317]. Let $\nu(x)-1$ be the ramification order at x. Let $\sigma = \{x \,|\, \nu(x) > 1\}$ be the set of ramification points. For $a = (a_1, \cdots, a_n) \in \mathbf{C}^n$ and $\rho > 0$ denote $C'(a, \rho) = \prod_{\nu=1}^n \{z \,|\, |z - a_\nu| < \rho\}$. For $a \in \mathfrak{D}$, at most one open connected neighborhood $C(a, \rho)$ of a exists such that $\pi: C(a, \rho) \to C'(a, \rho)$ is a surjective, proper map. For $B \subseteq \mathfrak{D}$, define

$$\delta(a, B) = \sup\{\rho \,|\, C(a, \rho) \text{ exists}, C(a, \rho) \cap B = \varnothing\}.$$

If $A \cap B = \varnothing$, define $\delta(A, B) = \inf\{\delta(a, B) \,|\, a \in A\}$. Define $\delta(a) = \delta(a, \varnothing)$ and $\delta(A) = \delta(A, \varnothing)$. If $0 < r < \delta(A)$, define $A(r) = \bigcup_{a\in A} C(a, r)$.

If f is holomorphic at a, let $(f)_a$ be the germ of f at a. If $a \in \mathfrak{D} - \sigma$, then π induces a germ $\pi^*(f)_a$ at $\pi(a)$. Now,

suppose that $\lambda \in H(\mathfrak{D})$ is given such that $L = \{x \mid \lambda(x) = 0\}$ does not contain an interior point, and such that λ vanishes at each $x \in \sigma$ with order $\nu(x)$. If $f \in H(\mathfrak{D})$, then the partial derivatives of f are defined and holomorphic on $\mathfrak{D} - \sigma$ and meromorphic on $\mathfrak{D}$ such that

$$g^{(f)}_{k_1 \cdots k_n} = \lambda^k \frac{\partial^k f}{\partial z_1^{k_1} \cdots \partial z_n^{k_n}}, \qquad k = k_1 + \cdots + k_n,$$

is holomorphic on $\mathfrak{D}$.

Now, let $\mathfrak{F}$ be a non-empty family of holomorphic functions on $\mathfrak{D}$ such that $f \in \mathfrak{F}$ implies $g^{(f)}_{k_1 \cdots k_n} \in \mathfrak{F}$ for all $k_1 \geq 0, \cdots, k_n \geq 0$ and $c \cdot f^k \in \mathfrak{F}$ for all $c \in \mathbf{C}$ and all integers $k \geq 0$. Suppose that $\mathfrak{D}_0$ is a relatively compact open subset E of $\mathfrak{D} - \sigma$ such that for every $a \in \hat{\mathfrak{D}}_0(F) - L$, for every $f \in \mathfrak{F}$ and for $\rho = |\lambda(a)| \delta(E, L)(\|\lambda\|_{\mathfrak{D}_0})^{-1}$, one and only one holomorphic function f^* on $C'(\pi(a), \rho)$ exists such that $(f^*)_{\pi(a)} = \pi^*(f)_a$. Moreover,

$$\|f\|_{E(r')} \quad \text{if} \quad 0 < \rho' < \rho \quad \text{and if} \quad r' = \rho^{-1} \rho' \delta(E, L).$$

If $\sigma = \varnothing$, this result gives the original theorem of Cartan and Thullen. *W. Stoll* (Notre Dame, Ind.)

★**Tables of natural and common logarithms to 110 decimals.**

Edited by A. J. Thompson. Royal Society Mathematical Tables, Vol. 8.

Published for the Royal Society at the Cambridge University Press, New York, 1964. xviii + 95 *pp.* \$7.50.

This is a remarkable volume to appear at this time, not because of its contents: log n and ln n for $n = 1(1)1000$ and log y and ln y for $y = 1 + x \cdot 10^{-q}$ for $q = 4(1)11$, $x = 1(1)9$, all to 110D, but because these were apparently computed without any mechanical aid by a retired accountant.

There is an introduction by A. J. Thompson, the author of *Logarithmetica Britannica* [Vols. I, II, Cambridge Univ. Press, New York, 1952 [published 1954]; MR **16**, 286], describing the use, construction and checking of the tables. The tables were reproduced photographically from sheets prepared on a card-controlled typewriter; a few blurred figures are clarified in an inset.

There is also a page of 110D values of relevant constants. *John Todd* (Pasadena, Calif.)

Bibliographisches Institut, Mannheim, 1964. viii + 211 *pp.*

The entries in these two volumes were computed to 10S on a Siemens 2002 and then rounded, usually to 4D; a few tables are given to different precisions, e.g., to 5S. The intervals are chosen to permit linear interpolation. We shall indicate the content of the main tables, using standard notations:

Vol. I: $J_0(x)$, $J_1(x)$, $N_0(x)$, $N_1(x)$, $0 \leq x < 16$; $e^{-x}I_0(x)$, $e^{-x}I_1(x)$, $e^xK_0(x)$, $e^xK_1(x)$, ber x, bei x, $0 \leq x < 10$; her x, $0 \leq x < 6$; hei x, $0.2 \leq x < 6$; the first hundred positive zeros of J_0 and J_1 and the corresponding values of J_1 and J_0.

Vol. II: $\Gamma(1+x)$, $0 \leq x < 1$; $\mathrm{Ei}(-x)$, $0 \leq x < 5$; $\mathrm{Si}(x)$, $\mathrm{Ci}(x)$, $0 \leq x < 20$; erf x, $0 \leq x < 4$; $1 - \operatorname{erf} x$, $4 \leq x \leq 10$; $C(x)$, $S(x)$, $0 \leq x < 10$; $K(k)$, $E(k)$, $0 \leq k < 1$; $\vartheta_r(\nu, \kappa)$, $r = 1, 2, 3, 4$, $0 \leq \nu \leq 1/2$, $\kappa = K(\cos\alpha)/K(\sin\alpha)$, $\alpha = 0(1°)87°$; $P_r(x)$, $r = 2(1)7$, $0 \leq x \leq 1$; $Q_r(x)$, $r = 0(1)7$, $0 \leq x < 1$; $l_n(x) = e^{x/2}D^n(e^{-x}x^n)/n!$, $n = 0(1)5$, $0 \leq x \leq 50$; $\varphi_n(x) = (-1)^n e^{x^2/2}D^n(e^{-x^2})$, $n = 0(1)5$, $0 \leq x < 10$.

Each table is prefaced by a few lines about asymptotic formulas, recurrence relations or functional equations which will enable one to obtain the functions outside the range for which they are actually tabulated.

{The printing is tolerable, but the paper is thin and the material on the reverse shows through. There are some editorial flaws, e.g., the preface to the first volume appears again in the second, and there seems to be no key to the references.} *John Todd* (Pasadena, Calif.)

A remark on Tricomi's ψ function.

J. Math. and Phys. **43** (1964), 261–262.

In this paper, the integral

$$E_q(u) = \int_u^\infty e^{-x} x^{-q}\, dx$$

is shown to be equal to the Tricomi function $e^{-u}\psi(q, q; u)$. Also a recurrence relation for $E_{M+n}(u)$ is proved, which should be useful in the numerical evaluation of integrals of this type. *L. J. Slater* (Cambridge, England)

Vilenkin, N. Ja. 3679

The hypergeometric function and representations of the group of real second-order matrices. (Russian)

Mat. Sb. (*N.S.*) **64** (**106**) (1964), 497–520.

A representation of the group G of 2×2 real unimodular matrices is obtained by putting

$$T_\chi(g)f(x) = |\beta x+\delta|^{\omega-1}\operatorname{sgn}^\epsilon(\beta x+\delta)f((\alpha x+\gamma)/(\beta x+\delta)),$$

where $g=\begin{Vmatrix}\alpha & \beta\\ \gamma & \delta\end{Vmatrix}\in G$, χ is a pair (ω, ϵ), ω complex, $\epsilon=\pm 1$, and f is a space D_χ of functions which, with $|x|^{\omega-1}\operatorname{sgn}^\epsilon xf(-x^{-1})$, are infinitely often differentiable [Gel'fand, Graev, and Vilenkin, *Generalized functions* (Russian), No. 5, Fizmatgiz, Moscow, 1962; MR 28 #3324]. Writing

$$F_+(\lambda) = \int_0^\infty x^\lambda f(x)\,dx, \qquad F_-(\lambda) = \int_0^\infty x^\lambda f(-x)\,dx,$$

$-1<\operatorname{Re}\lambda<-\operatorname{Re}\omega$, this generates a representation $T_\chi(g)F(\lambda)=\int K(\lambda, \mu; \chi; g)F(\mu)\,d\mu$ in the space of pairs $F(\lambda)=(F_+(\lambda), F_-(\lambda))$, where K is a 2×2 matrix of functions and the integral is along the line $\operatorname{Re}\mu=a$, $-1<a<-\operatorname{Re}\omega$. In particular, for the matrices $h(\theta)=\begin{Vmatrix}\cosh\theta & \sinh\theta\\ \sinh\theta & \cosh\theta\end{Vmatrix}$ or $u(\theta)=\begin{Vmatrix}\cos\theta & -\sin\theta\\ \sin\theta & \cos\theta\end{Vmatrix}$ the elements of K are expressible in terms of hypergeometric functions, and for the matrix $Z=\begin{Vmatrix}1 & 0\\ z & 1\end{Vmatrix}$ in terms of powers. The integral formulae corresponding to the equations $T_\chi(g)^{-1}=T_\chi(g^{-1})$, $T_\chi(gh)=T_\chi(g)T_\chi(h)$, written out explicitly, lead to inversion formulae for integral transforms on the one hand and to formulae for hypergeometric functions $F(\lambda, \mu; \nu, x)$ as Mellin transforms in x, which include several of Barnes' formulae, and to formulae for these functions as Mellin transforms with respect to the variable ν. *J. L. B. Cooper* (Pasadena, Calif.)

Vilenkin, N. Ja. 3680

Functional composition theorems for the hypergeometric function. (Russian)

Mat. Sb. (*N.S.*) **65** (107) (1964), 28–46.

The representations of the group of 2×2 real unimodular matrices described above [#3679] are used to produce numerous formulae for integrals of products of hyperbolic functions $F(\lambda, \mu; \nu; z)$ with respect to their parameters, some of which are related to formulae discovered by Ramanujan. *J. L. B. Cooper* (Pasadena, Calif.)

Wimp, Jet; Luke, Yudell L. 3681

Expansion formulas for generalized hypergeometric functions.

Rend. Circ. Mat. Palermo (2) **11** (1962), 351–366.

In this paper, the authors prove two very general theorems which express a generalized hypergeometric function $F[wz]$ in terms of the sum of a series of products of generalized hypergeometric functions $F[z]$ and $F[w]$.

They state the conditions under which their theorems are true, and they generalize their results still further to prove two theorems which express the Meijer G-function, $G[wz]$ in terms of the sum of a series of products of a generalized G-function $G[z]$ and a generalized hypergeometric function $F[w]$.

The paper concludes with several interesting examples of the application of these theorems to Laguerre polynomials, Hermite polynomials and Bessel functions.

L. J. Slater (Cambridge, England)

Sharma, K. C. 3682

Integrals involving products of G-function and Gauss's hypergeometric function.

Proc. Cambridge Philos. Soc. **60** (1964), 539–542.

Author's introduction: "The first result to be established here is

$$\int_0^1 x^{\rho-1}(1-x)^{\beta-\gamma-n}{}_2F_1(-n, \beta; \gamma; x)G^{k,l}_{p,q}\left(zx^m\middle|\begin{matrix}a_1, \cdots, a_p\\ b_1, \cdots, b_q\end{matrix}\right)dx$$

$$(1)\qquad = \frac{\Gamma(\gamma)\Gamma(\beta-\gamma+1)}{\Gamma(\gamma+n)}m^{\gamma-\beta+n-1}G^{k+m,l+m}_{p+2m,q+2m}(\mathrm{I}),$$

where (I) stands for

$$\left(z\middle|\begin{matrix}\frac{1-\rho}{m}, \ldots, \frac{m-\rho}{m}, a_1, \ldots, a_p, & \frac{\gamma-\rho}{m}, & \ldots, \frac{\gamma-\rho+m-1}{m}\\ \frac{\gamma+n-\rho}{m}, \ldots, \frac{\gamma+n-\rho+m-1}{m}, b_1, \ldots, b_q, & \frac{\gamma-\beta-\rho}{m}, & \ldots, \frac{\gamma-\beta-\rho+m-1}{m}\end{matrix}\right),$$

and where m and n both are positive integers. The result (1) holds if $\Re(\rho+mb_h)>0$, $h=1, \cdots, k$; $\Re(\beta-\gamma)>n-1$, and one of the following conditions is satisfied:

(i) $2(k+l) > p+q$, $\quad |\arg z| < (k+l-\frac{1}{2}p-\frac{1}{2}q)\pi$;

(ii) $2(k+l) \geq p+q$, $\quad |\arg z| \leq (k+l-\frac{1}{2}p-\frac{1}{2}q)\pi$ and
$\Re(\sum a_j-\sum b_j+\frac{1}{2}(q-p)+\beta-\gamma-n) > 1$.

The second result to be established is

$$(2)\quad \int_0^1 x^{\rho-1}(1-x)^{\beta-\alpha-1}{}_2F_1(\alpha, \beta; \gamma; x)G^{k,l}_{r,s}\left(zx^n(1-x)^{-n}\middle|\begin{matrix}a_1, \cdots, a_r\\ b_1, \cdots, b_s\end{matrix}\right)dx$$

$$= \frac{\Gamma(\gamma)}{\Gamma(\beta)\Gamma(\gamma-\alpha)}(2\pi)^{1-n}n^{\beta-\alpha-1}G^{k+2n,l}_{r+2n,s+2n}(\mathrm{J}),$$

where (J) stands for

$$\left(z\middle|\begin{matrix}\frac{1-\rho}{n}, \ldots, \frac{n-\rho}{n}, a_1, \ldots, a_r, \frac{\gamma-\rho}{n}, & \ldots, \frac{\gamma-\rho+n-1}{n}\\ \frac{\beta-\rho}{n}, \ldots, \frac{\beta-\rho+n-1}{n}, & \frac{\gamma-\alpha-\rho}{n}, \ldots, \frac{\gamma-\alpha-\rho+n-1}{n}, b_1, \ldots, b_s\end{matrix}\right),$$

and where n is a positive integer, $\Re(\rho+nb_h)>0$, $h=1, \cdots, k$; $\Re(\gamma-\alpha-\rho-na_t+n)>0$, $\Re(\beta-\rho-na_t+n)>0$, $t=1, \cdots, l$; $2(k+l)>r+s$, $|\arg z|<(k+l-\frac{1}{2}r-\frac{1}{2}s)\pi$."

The proofs of the above results start from an integral representation of the G-function, from a formula for $\Gamma(mz)$ and from an integral of the hypergeometric function multiplied by polynomials. These four formulas are taken from two handbooks [Erdélyi et al., *Higher transcendental functions*, Vol. I, McGraw-Hill, New York, 1953; MR 15, 419; *Tables of integral transforms*, Vol. II, McGraw-Hill, New York, 1954; MR 16, 468]. The proofs proper are then effected by substitutions. *M. J. O. Strutt* (Zürich)

Carlitz, L. 3683

Another Saalschützian theorem for double series.

Rend. Sem. Mat. Univ. Padova **34** (1964), 200–203.

In this paper, the author proves a second summation theorem for a double Appell F_1 series of the Saalschützian type. He uses this result to express a series of Appell F_1 functions as a simple ${}_3F_2(x)$ ordinary hypergeometric series. *L. J. Slater* (Cambridge, England)

Particular solutions are found for the equation

$$\left[z\frac{d}{dz}\prod_{k=1}^{q}\left(z\frac{d}{dz}+\beta_k-1\right)-z\prod_{k=1}^{q}\left(z\frac{d}{dz}+\alpha_k\right)\right]W+Az^\lambda = 0$$

for $\lambda=0,-1,-2,\cdots$, and β_k, α_k, and A are constants. *S. Drobot* (Columbus, Ohio)

Khandekar, P. R. 3688

A note on the associated Legendre polynomials.

Proc. Glasgow Math. Assoc. **6**, 156–160 (1964).

The aim of this paper is to give a new Rodrigues' formula for the associated Legendre polynomials $P_n^m(x)$ if m is an even positive integer. In the first part, starting from Gegenbauer polynomials, the function $P_n^{2k}(x)$ is expressed by a generalized hypergeometric function. In the second part, this expression is modified so as to obtain the above Legendre function as the nth derivative of a generalized hypergeometric function. The third and fourth parts are concerned with integrals between the limits -1 and $+1$ of a polynomial in x and the product of two Legendre functions of equal k, as well as different k. These integrals are also expressed by generalized hypergeometric functions. *M. J. O. Strutt* (Zürich)

Piefke, Gerhard 3689

Asymptotische Näherungen der modifizierten Mathieuschen Funktionen. (English and Russian summaries)

Z. Angew. Math. Mech. **44** (1964), 315–327.

The solutions of the modified Mathieu equation

$$f''(\xi)+[2h^2\cosh 2\xi-\vartheta]f(\xi) = 0,$$

where ϑ is one of the periodic or half-periodic eigenvalues $a_m(h^2)$, $b_{m+1}(h^2)$, $m=0,1,2,\cdots$, are studied for real ξ and large real values of the parameter h. The procedure consists essentially in writing $f(\xi)=\exp[ht(\xi,h)]$ and in expanding $t(\xi,h)$ in descending powers of h. First approximations of the solutions in $-\infty<\xi<\infty$ are given. The quality of the approximation is demonstrated in eighteen figures. Better approximations have already been obtained by Goldstein [Trans. Cambridge Philos. Soc. **23** (1927), 303–336]. *J. Meixner* (Aachen)

Müller, H. J. W. [Müller, Harald J. W.] 3690

On asymptotic expansions of Mathieu functions.

J. Reine Angew. Math. **211** (1962), 179–190.

Mathieu's differential equation

$$y''(x)+[\lambda-2h^2\cos 2x]y(x) = 0$$

is studied for large positive values of h in the interval $0\le x\le 2\pi$. The substitutions $\omega(x)=4h^{1/2}\cos(\pi/4\pm x/2)$ and $X(\omega)=\exp(\pm 2h\sin x)y(x)$ are made, with independent $\pm$ signs. The solutions $X(\omega)$ are expanded in terms of Hermite polynomials of the variables ω and $i\omega$, respectively. The first coefficients in these expansions are explicitly given. *J. Meixner* (Aachen)

Müller, Harald J. W. 3691

Asymptotic expansions of prolate spheroidal wave functions and their characteristic numbers.

J. Reine Angew. Math. **212** (1963), 26–48.

The differential equation of prolate spheroidal wave functions

$$(1-u^2)Y''(u)-2uY'(u)$$
$$+[\Lambda+4h^2(1-u^2)-m^2(1-u^2)^{-1}]Y(u) = 0$$

is studied for large positive values of h in the interval $-1\le u\le 1$. The substitutions $u=\cos x$ and $X(x)=\exp(\pm 2h\sin x)(\sin x)^{1/2}Y(u)$ yield a differential equation whose solutions are expanded in terms (1) of the functions

$$A_q(x) = \cos^{(q-1)/2}\left(\frac{\pi}{4}+\frac{x}{2}\right)\Big/\cos^{(q+1)/2}\left(\frac{\pi}{4}-\frac{x}{2}\right),$$

(2) of the Hermite polynomials $H_{(q-1)/2}(z)$, where $z=4h^{1/2}\cos(\pi/4+x/2)$, and (3) of the Hermite polynomials $H_{(q-1)/2}(i\zeta)$, where $\zeta=z(-x)$. The various expansions which are suitable in different but overlapping parts of the interval $0\le x\le\pi$ are linked together. In all expansions only a few terms are explicitly evaluated. But a general procedure is given for the evaluation of all coefficients in the expansion of the eigenvalues. *J. Meixner* (Aachen)

Dingle, R. B.; Müller, H. J. W. 3692

The form of the coefficients of the late terms in asymptotic expansions of the characteristic numbers of Mathieu and spheroidal-wave functions.

J. Reine Angew. Math. **216** (1964), 123–133.

In a series of papers [Proc. Roy. Soc. London Ser. A **244** (1958), 456–475; MR **21** #2145; ibid. **244** (1958), 476–483; MR **21** #2146; ibid. **244** (1958), 484–490; MR **21** #2147; ibid. **249** (1959), 270–283; MR **21** #2148a; ibid. **249** (1959), 284–292; MR **21** #2148b; ibid. **249** (1959), 293–295; MR **21** #2148c], R. B. Dingle developed a method for replacing

the divergent remainders of asymptotic expansions by series involving convergent factors, and applied his method to a variety of special functions. In another series [H. J. W. Müller and R. B. Dingle, J. Reine Angew. Math. **211** (1962) 11–32; MR **26** #1513; Müller, ibid. **211** (1962), 33–47; MR **26** #1514; Müller, #3690 and #3691 above], H. J. W. Müller, and the authors jointly, applied Dingle's method to Mathieu and spheroidal wave functions. The present work establishes the form of the coefficients of the late terms in the asymptotic expansions of the characteristic numbers of these functions, by means of the asymptotic solution of a partial difference equation. No error estimates are given, but some numerical evidence is furnished that the authors' approximations yield a correct solution. *I. Marx* (Lafayette, Ind.)

Hirschman, I. I., Jr. 3693

Extreme eigenvalues of Toeplitz forms associated with orthogonal polynomials.

J. Analyse Math. **12** (1964), 187–242.

Let $\Omega(dx)$ be a non-negative Borel measure on the real line with infinite spectrum $\sigma(\Omega)$ and for which moments of all orders exist. Let $P(n, x)$, $n = 0, 1, \cdots$, be the orthogonal polynomials associated with Ω, with

$$\int P(n, x)P(m, x)\Omega(dx) = \delta_{nm}h(n).$$

Given a real bounded continuous function $f(x)$ on $\sigma(\Omega)$, define

$$c(p, q) = \{h(p)h(q)\}^{-1/2}\int f(x)P(p, x)P(q, x)\Omega(dx).$$

Under study are the extreme eigenvalues of the Toeplitz matrix $[c(p, q)]_{p,q=0,\cdots,n}$ for the systems of Jacobi, Laguerre, and Hermite polynomials. Let the eigenvalues be $\lambda_{n,1} \geq \lambda_{n,2} \geq \cdots \geq \lambda_{n,n+1}$, and assume that f attains its maximum M at exactly one point x_0 of $\sigma(\Omega)$; if x_0 is interior to $\sigma(\Omega)$, assume $f''(x_0) \neq 0$, and if x_0 is an endpoint of $\sigma(\Omega)$, assume $f'(x_0) \neq 0$. It is shown that for fixed $\nu = 1, 2, \cdots$,

$$\lambda_{n,\nu} = M - \alpha_\nu n^{-e} + o(n^{-e}),$$

where the α_ν are explicit constants depending only on $f''(x_0)$ or $f'(x_0)$ and the polynomial system under consideration, and e is 1 or 2. The author has subsequently treated the more general case where f has arbitrary order of contact at its maximum for the systems of Jacobi polynomials [Pacific J. Math. **14** (1964), 107–161; MR **28** #4391] and ultraspherical polynomials [J. Math. Mech. **13** (1964), 249–282; MR **28** #3351]. *H. Widom* (Ithaca, N.Y.)

Makai, E.; Turán, P. 3694

Hermite expansion and distribution of zeros of polynomials. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 157–163.

The purpose of this paper is to prove a theorem in the theory of Hermite expansions corresponding to the Landau-Fejér-Montel theory of polynomial expansions, this theorem being that the Hermite trinomial equation

$$f(z) = 1 + H_1(z) + \xi H_n(z) = 0,$$

where ξ is arbitrary and complex, always has at least one of its zeros in the strip $|y| \leq A$, A being a positive constant. This theorem is a consequence of the theorem: The above equation has for $n \geq 36$ at least one zero in the strip $|y| \leq e^3$. The proof of the latter theorem is involved. It starts from recurrence formulas for Hermite functions, from inequalities of G. Szegö and van Veen, and proceeds to a lemma giving an inequality for the absolute value of a Hermite function on the circle $|z - \xi_n| = \xi_n - \xi_{n-1}$, where ξ_n is the maximal zero of $H_n = 0$. This inequality is transformed somewhat and then leads to a proof of the second theorem above. Considering the case $n \leq 35$, a proof of the first theorem is obtained. *M. J. O. Strutt* (Zürich)

Chatterjea, S. K. 3695

On a paper of Banerjee.

Boll. Un. Mat. Ital. (3) **19** (1964), 140–145.

After the author points out that a paper of Banerjee [Proc. Nat. Acad. Sci. India Sect. A **29** (1960), 83–86; MR **26** #1505] contains some incorrect results and others which are already known, he goes on to evaluate the Christoffel-Darboux expression

$$\frac{\sigma_{n(x,z)}}{x - z} = y_{n+1}(x)y_n(z) - y_{n+1}(z)y_n(x),$$

where $y_n(x)$ is the nth Bessel polynomial of Krall and Frink [Trans. Amer. Math. Soc. **65** (1949), 100–115; MR **10**, 453]. The author fails to note that his formulas are special cases of some results for the generalized Bessel polynomials which the reviewer has already stated [Duke Math. J. **26** (1959), 519–539; MR **22** #120]. *W. A. Al-Salam* (Lubbock, Tex.)

Chatterjea, S. K. 3696

Integral representation for the product of two Jacobi polynomials.

J. London Math. Soc. **39** (1964), 753–756.

The author proves the following formula.

$$P_m^{(\alpha,\beta)}(x)P_n^{(\alpha',\beta')}(y) = \frac{2^{m+n+\alpha+\alpha'}}{\pi^2}$$

$$\times \frac{\Gamma(\alpha+\alpha'+\beta+\beta'+m+n+2)}{\Gamma(\alpha+\beta+m+1)\Gamma(\alpha'+\beta'+n+1)}\,\frac{\Gamma(\alpha+m+1)\Gamma(\alpha'+n+1)}{\Gamma(\alpha+\alpha'+m+n+1)}$$

$$\times \int_0^1 \int_{-\pi/2}^{\pi/2} \int_{-\pi/2}^{\pi/2} t^{m+\alpha+\beta}(1-t)^{n+\alpha'+\beta'} e^{(m-n)\theta i+(\alpha-\alpha')\phi i}$$

$$\times \cos^{m+n}\theta \cos^{\alpha+\alpha'}\phi$$

$$\times P_{m+n}^{(\alpha+\alpha',\beta+\beta'+1)}\left\{1 - \frac{[xte^{(\phi-\theta)i} + y(1-t)e^{(\theta-\phi)i}]2\cos\phi}{\cos\theta}\right\} d\phi\, d\theta\, dt$$

$$(\beta, \beta' > -1;\ \alpha+\alpha' > -1).$$

The method is similar to the method used by the reviewer [Boll. Un. Mat. Ital. (3) **17** (1962), 25–28; MR **25** #1318] in obtaining a double integral representation for the product of two Laguerre polynomials. *L. Carlitz* (Durham, N.C.)

Chatterjea, S. K. 3697

On a generalization of Laguerre polynomials.

Rend. Sem. Mat. Univ. Padova **34** (1964), 180–190.

If k is a postive integer,

$$\frac{1}{n!}x^{-\alpha}e^{px^k}\frac{d^n}{dx^n}(x^{\alpha+n}e^{-px^k})$$

is a polynomial of degree n; it is denoted by $T_{kn}^{(\alpha)}(x,p)$. $T_n^{(\alpha)}(x,1)=L_n^{(\alpha)}(x)$, the Laguerre polynomial. An explicit formula, an operational formula, a generating function, and various recurrence formulas are obtained, which are generalizations of the corresponding formulas for Laguerre polynomials. Of particular interest are the following relations:

$$(1)\qquad T_n^{(\alpha)}(x,m)=L_n^{(\alpha)}(mx),$$

$$(2)\qquad T_{kn}^{(\alpha+\beta+1)}(x,p+q)=\sum_{m=0}^{n}T_{km}^{(\alpha)}(x,p)T_{k(n-m)}^{(\beta)}(x,q),$$

$$(3)\qquad H_{kn}^{(\alpha)}(x,p)=(-1)^n n!\,T_{kn}^{(\alpha-n)}(x,p),$$

where $H_{kn}^{(\alpha)}(x,p)$ are the generalized Hermite polynomials defined by Gould and Hopper [Duke Math. J. **29** (1962), 51–63; MR **24** #A2689].

A. E. Danese (Buffalo, N.Y.)

Abdul-Halim, N.; Al-Salam, W. A. 3698

A characterization of the Laguerre polynomials.

Rend. Sem. Mat. Univ. Padova **34** (1964), 176–179.

Two proofs are given of the result that the only orthogonal polynomials of the form

$${}_{p+1}F_q\left[\begin{matrix}-n,\alpha_1,\alpha_2,\cdots,\alpha_p;\\ \beta_1,\beta_2,\cdots,\beta_q;\end{matrix}\; x\right],$$

where n is a non-negative integer, and the α's and β's are independent of x and n, are ${}_1F_1[-n;\beta;x]$. (These are the Laguerre polynomials $L_n^{(\beta-1)}(x)$ with normalization $L_n^{(\beta-1)}(0)=1$.)

One of the proofs follows directly from the general recurrence relation for orthogonal polynomials and the definition of the confluent hypergeometric function; the other proof is more elegant and is established from current results.

A. E. Danese (Buffalo, N.Y.)

Gatteschi, Luigi 3699

Proprietà asintotiche di una funzione associata ai polinomi di Laguerre e loro utilizzazione al calcolo numerico degli zeri dei polinomi stessi.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 113–124.

Taking his clue from the asymptotic representation of Laguerre polynomials $L_n^{(\alpha)}(x)$ as $\nu=4n+2\alpha+2\to\infty$ while α is fixed and $t=x/\nu$ is restricted to a closed subinterval of $(0,1)$, the author writes, for $0<t<1$,

$$L_n^{(\alpha)}(\nu t)=A_n^{(\alpha)}(t,\nu)\sin[\theta(t)-\nu^{-1}A(t)-\eta_n^{(\alpha)}(t)],$$

where θ and A are certain elementary functions known from the asymptotic representation. Let $\nu\tau_{n,r}^{(\alpha)}$ be the rth zero of $L_n^{(\alpha)}(x)$. The author shows that for fixed r and s, $\eta_n^{(\alpha)}(\tau_{n,r}^{(\alpha)})$ and $\eta_n^{(\alpha)}(\tau_{n,n-s+1}^{(\alpha)})$ approach finite limits as $n\to\infty$, and expresses these limits in terms of the rth zero of $J_\alpha(x)$ and the sth zero of $\mathrm{Ai}(-x)$, respectively. He then describes the application of his results to the computation of the zeros of Laguerre polynomials.

Parodi, Maurice 3700

Sur quelques propriétés des zéros des polynomes de Laguerre.

C. R. Acad. Sci. Paris **258** (1964), 5303–5304.

Starting from the differential equation of Laguerre polynomials, the author transforms it in such a way as to eliminate the first-order term. This equation is then compared with an equation, a particular solution of which may be expressed by a Bessel function of the first kind of order unity. Considering the first two consecutive (real) zeros of the latter solution, the application of Sturm-Liouville properties yields the situation that the first zero of the Laguerre polynomial of order $n\geq 6$ is between the two consecutive zeros. Thus bounds for this first zero appear. Also, bounds for generalized Laguerre polynomials are derived in this way.

M. J. O. Strutt (Zürich)

Rangarajan, S. K. 3701

Generalised Angelescu polynomials: Some properties.

Proc. Indian Acad. Sci. Sect. A **60** (1964), 65–73.

The author defines a set of polynomials $\{\pi_n^\alpha(x)\}$ by means of

$$\frac{\pi_n^\alpha(x)}{(1+\alpha)_n}=\sum_{m=0}^{n}(-1)^m\binom{n}{m}\frac{A_m(x)}{(1+\alpha)_m},$$

where $A_m(x)\equiv(a_0,a_1,\cdots,a_m,x,1)^m$. Thus for $\alpha=0$, $\pi_n^\alpha(x)$ reduces to Angelescu's polynomial $\pi_n^\alpha(x)$ [C. R. Acad. Sci. Roumaine **2** (1938), 199–201]. The author obtains various results concerning $\pi_n^\alpha(x)$, thus generalizing known properties of $\pi_n(x)$. For example, $\pi_n^\alpha(x)=n!L_n^\alpha(x)$, where $L_n^\alpha(x)$ is the Laguerre polynomial, and

$$\pi_n^{\alpha+\beta+1}(x+y)=\sum_{m=0}^{n}\binom{n}{m}m!L_m^\alpha(x)\pi_{n-m}^\beta(y).$$

The general identity

$$\sum_{r=0}^{n}\frac{\pi_r^\alpha(x)t^rf^{(r)}(z)}{\Gamma!(1+\alpha)_r}=\sum_{r=0}^{n}\frac{(-1)^rA_r(x)f^{(r)}(z+t)}{\Gamma!(1+\alpha)_r},$$

where $f(z)$ is an arbitrary polynomial of degree n, is proved, and some special cases noted.

Bandić, Ivan 3703

Sur une classe d'équations différentielles non-linéaires à plusieurs dimensions. (Serbo-Croatian summary)

Glasnik Mat.-Fiz. Astronom. Društvo Mat. Fiz. Hrvatske Ser. II **18** (1963), 61–68.

The author considers differential equations of the form

$$f_n(x, y) + \sum_{k=0}^{n-1} f_k(x, y) y^{(n-k)} = 0,$$

where the $f_k(x, y)$ are entire rational functions of dimension m_k, in the case where x has dimension λ and y has dimension ν. Thus, for example, $x(y+x^2)$ has dimension 3 whenever $\lambda = 1$ and $\nu = 2$. It is shown that if λ, ν and m_k satisfy certain conditions, then an equation of order n can be reduced to an equation of order $n-1$.

N. P. Bhatia (Cleveland, Ohio)

Hukuhara, Masuo 3704

On the zeros of solutions of linear ordinary differential equations. (Japanese)

Sûgaku **15** (1963), 108–109.

The author proved the following result: Consider an nth-order linear ordinary differential equation

$$\text{(A)} \qquad y^{(n)} + p_1(x) y^{(n-1)} + \cdots + p_n(x) y = 0,$$

where the coefficients $p_j(x)$ are bounded and measurable functions on an x-interval I. Then the length of the interval I should not be less than the positive root of the algebraic equation

$$\text{(B)} \qquad M_1 \|p_1\| \left(\frac{x}{2}\right) + M_2 \|p_2\| \left(\frac{x}{2}\right)^2 + \cdots + M_n \|p_n\| \left(\frac{x}{2}\right)^n = 1,$$

where $M_{2k} = 1/(2(k!)^2)$, $M_{2k+1} = 1/((2k+1)(k!)^2)$, and $\|p_k\| = \sup_{x \in I} |p_k(x)|$, in order that the differential equation (A) admits a solution which has at least n zeros in the interval I.

This result is a refinement of the result due to T. Sato [Kansu-Hoteisiki **22** (1940), 39–43]. T. Sato assumed that the $p_j(x)$ are continuous, and he used the algebraic equation

$$\|p_1\| \left(\frac{x}{2}\right) + \|p_2\| \left(\frac{x}{2}\right)^2 + \cdots + \|p_n\| \left(\frac{x}{2}\right)^n = 1$$

in place of (B). On the other hand, M. Tumura [ibid. **30** (1941), 20–35] also previously proved a result in which he assumed the continuity of the p_j, and he used the algebraic equation

$$\frac{(n-1)^{n-1}}{n^n \cdot n!} \|p_n\| x^n + \sum_{k=1}^{n-1} \frac{(n-k)}{n \cdot k!} \|p_k\| x^k = 1$$

in place of (B). The author gives no definite comparison between Tumura's result and his. (Cf. W. B. Fite [Ann. of Math. (2) **18** (1917), 214–220], M. Nagumo [Japan. J. Math. **5** (1928), 225–238], and C. de La Vallée Poussin [J. Math. Pures Appl. (9) **8** (1929), 125–144].) The author also considers the case when the p_j are Lebesgue integrable on I. In this case he uses the algebraic equation

$$M_0 \|p_1\| \left(\frac{x}{2}\right) + \cdots + M_{n-1} \|p_n\| \left(\frac{x}{2}\right)^n = 1$$

in place of (B), where $\|p_j\| = \int_I |p_j(x)|\, dx$.

Y. Sibuya (Minneapolis, Minn.)

Gray, H. L. 3705

Application of the Holmgren-Riesz transform.

Ann. Scuola Norm. Sup. Pisa (3) **18** (1964), 57–65.

The Holmgren-Riesz transform is applied to the equation

$$(a_2 x^2 + b_2 x + c_2) y'' + (a_1 x + b_1) y' + c_0 y = 0,$$

where a_1, a_2, b_1, b_2 and c_0 are real constants. Starting from appropriate definitions of the Holmgren-Riesz transform, the equivalent HR form of this equation is given, introducing an exponential function. The proof of this HR form follows by its expansion. Defining the first $n-1$ arbitrary constants of the HR form to be zero, the general solution of the above differential equation is obtained. Specializing, a "generalized" Rodrigues formula is defined. This is then applied to the differential equation of Laguerre functions, thus obtaining generalized Laguerre polynomials, as is proved by direct series expansion. Next, the differential equation of Legendre functions is considered. Application of the HR transform gives its solution, and suggests some formulas for these functions. The proofs again follow by direct series expansion. Finally, the solution of the hypergeometric differential equation is obtained in the same way.

M. J. O. Strutt (Zürich)

Aniščenko, R. I. 3706

On a boundary-value problem. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 481–492.

The differential equation considered in this paper is

$$\varphi'' = f(x, \varphi) \psi(x)$$

with conditions

$$\varphi(0) = y_0, \qquad R\varphi'(R) - \varphi(R) = q$$

for $0 \le x \le R$, where y_0, R, q are given real numbers $y_0 > 0$, $R > 0$. The solution sought, $\varphi(x)$, is to be nonnegative. A number of conditions have been imposed on $f(x, \varphi)$ and ψ. Problems of this type arise in the statistical theory of the atom, and these conditions follow naturally from the physical setting of the problems. Continuous dependence of the interval of existence of the solution and the continuous dependence of the solution itself on the boundary values have been established.

P. K. Ghosh (Calcutta)

Kibenko, A. V. 3707

The Green's function for an ordinary first-order differential equation with a parameter. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1963**, 310–314.

Given the boundary-value problem

$$\frac{dx}{dt} = A(t) x + B(t) \lambda + f(t),$$

$$Cx(t_0) + Dx'(t_0) = \xi,$$

$$Fx(t_1) + Rx'(t_1) = \eta,$$

where $A(t)$, $B(t)$ are matrices which are continuous in $J = \langle t_0, t_1 \rangle$, C, D, F, R are constant matrices, $f(t)$ is a vector function which is continuous in J, λ is a vector parameter, and ξ, η are constant vectors. The author proves theorems on the existence of a Green's function for this system.

M. Ráb (Brno)

Coffman, Charles V. 3708
On the uniqueness of solutions of a non-linear boundary value problem.
J. Math. Mech. **13** (1964), 751–763.

The article deals with the boundary-value problem $v''+f(x,v)=0$, $v(0)=v'(b)=0$ $(b>0)$, where (i) $f(x,v)=vg(x,v)$, with $g>0$ and in C^1 on $x>0$, $|v|<\infty$; (ii) $f_v>0$ and $vg_v<0$ for $v\neq 0$; (iii) $xf_v(x,0)\leq M$ on $0<x<\delta$; and (iv) $\lim_{v\to\infty} g(x,v)=\lim_{v\to-\infty} g(x,v)$. With more special assumptions on f, the problem has been studied by I. I. Kolodner [Comm. Pure Appl. Math. 8 (1955), 395–408; MR 17, 154] and by G. H. Pimbley, Jr. [J. Math. Mech. 11 (1962), 121–138; MR 25 #2262a]. The question asked is whether a solution $v_n(x)$ of the boundary-value problem is uniquely determined by the requirement that it have $n-1$ zeros on $(0,b)$ and satisfy $v_n'(0)>0$. A sufficient condition is given for uniqueness, one involving a certain ordering of the zeros of several functions associated with the problem. For $n=1$ the condition reduces to a classical one of E. Picard (originally established under more restrictive assumptions). The general condition is satisfied also when f has the special form

$$f(x)=\phi\left(v\exp 2\int_1^x h^{-1}(t)\,dt\right),$$

where $h(x)+x$ is non-positive and monotone non-increasing. The last generalizes a result of Kolodner [loc. cit.].

Robert McKelvey (Boulder, Colo.)

Everitt, W. N. 3709
Singular differential equations. I. The even order case.
Math. Ann. **156** (1964), 9–24.

The author extends his earlier results [J. London Math. Soc. 37 (1962), 372–384; MR 25 #2261; Math. Ann. 149 (1962/63), 320–340; MR 27 #2668] on the use of boundary functions in boundary-value problems for differential equations with complex coefficients on finite intervals, to the case where the differential equation has a singularity at one end of the finite interval or where the interval is a half-line. The treatment is similar in both cases, and only the second case is considered. The differential equation is of the form $L\phi=\lambda\phi$, where λ is complex and L is an even-order, linear, formally self-adjoint differential operator with complex coefficients. There are obtained certain extensions of the limit-point, limit-circle theory (due to Weyl) for the second-order real case.

C. R. Putnam (Lafayette, Ind.)

Javrjan, V. A. 3710
The spectral shift function for Sturm-Liouville operators. (Russian. Armenian summary)
Akad. Nauk Armjan. SSR Dokl. **38** (1964), 193–198.

Consider

$$(1)\qquad H_2y=-y''+q(r)y,\quad y(0)=0,\quad 0\leq r<\infty,$$

with the domain of the operator H_2 in $L_2(0,\infty)$. Let $\psi(r,k)$ be a solution of the problem

$$-\psi''+q\psi-\lambda\psi=0,\quad \lambda=k^2,\quad \psi(0,k)=0,\quad \psi'(0,k)=1.$$

Put $M(k)=1+\int_0^\infty e^{ikr}q(r)\psi(r,k)\,dr$, $\operatorname{Im} k\geq 0$, $A(k)=|M(k)|$, $\delta(k)=\arg M(k)$ for $\operatorname{Im} k=0$. If q is real-valued and satisfies

$$(2)\qquad \int_0^1 r|q(r)|\,dr+\int_1^\infty |q(r)|\,dr<\infty,$$

then the following asymptotic formulas are valid:

$$\psi(r,k)\sim -\frac{M(k)}{2ik}e^{-ikr},\qquad r\to\infty,\quad \operatorname{Im} k>0,$$
$$\sim A(k)\sin(kr-\delta(k)),\qquad r\to\infty,\quad \operatorname{Im} k=0.$$

V. S. Buslaev and L. D. Faddeev [Dokl. Akad. Nauk SSSR 132 (1960), 13–16; MR 22 #11171] proved that under the supposition $\int_0^\infty r|q(r)|\,dr<\infty$ the spectral shift function for (1) is of the form

$$(3)\qquad \xi(\lambda)=\frac{1}{\pi}\delta(\sqrt{\lambda}),\qquad \lambda>0,$$
$$=-\int_{-\infty}^{\lambda}\sum_l \delta(t-\lambda_l)\,dt,\qquad \lambda<0,$$

where λ_l denotes points of the negative spectrum of H_2 and $M(\sqrt{\lambda})=\det(E+qR_\lambda)-R_\lambda$ is the resolvent of H_0. The author proves that the formulas (3) are valid under supposition (2) and that $M(\sqrt{\lambda})=\det(E+R_\lambda^{1/2}qR_\lambda^{1/2})$, $\arg\lambda\neq 0$.

M. Ráb (Brno)

Valakmadze, T. S. 3711
Multi-point linear boundary-value problems. (Russian. Georgian summary)
Soobšč. Akad. Nauk Gruzin. SSR **35** (1964), 29–36.

The author uses the method of Š. E. Mikeladze [Izv. Akad. Nauk SSSR Otd. Mat. Estest. Nauk 1935, 255–300] for the approximate solution of the boundary-value problem

$$y^{(n)}+X_1(x)y^{(n-1)}+\cdots+X_n(x)y=X_0(x),$$

where X_i are continuous in $\langle 0,l\rangle$ and

$$(1)\qquad \sum_{s=1}^{m}\sum_{j=0}^{n-1}a_{ij}^{(s)}y^{(j-1)}(x_s)=\gamma_i\qquad (i=1,2,\cdots,n),$$
$$0\leq x_1<x_2<\cdots<x_m\leq l,$$

under the supposition that this problem has a unique solution. The existence and uniqueness of the solution is proved when the boundary conditions (1) are of the form $y^{(j-1)}(x_i)=\gamma_{ij}$ $(i=1,\cdots p;\ j=1,\cdots,n_i;\ \sum_{i=1}^p n_i=n)$.

Ahmedova, A. M. [Guseinbekova, A. M.] 3712
Asymptotic expansion of eigenfunctions and eigenvalues in problems with a narrow deep potential well. (Russian. Azerbaijani summary)
Akad. Nauk Azerbaĭdžan. SSR Dokl. **20** (1964), no. 6, 3–7.

The purpose of the paper is to establish expansions in powers of $\varepsilon\to 0+$ for the eigenvalues and eigenfunctions of the operator

$$L_\varepsilon y=-y''+c_\varepsilon(x)y$$

for the boundary conditions $y(0)=y(+\infty)=0$ and the

transition conditions $y(\varepsilon^\beta-)=y(\varepsilon^\beta+)$, $y'(\varepsilon^\beta-)=y'(\varepsilon^\beta+)$, the coefficient $c_\varepsilon(x)$ having the form

$$c_\varepsilon(x) = -\varepsilon^{-2\beta}c_-(x\varepsilon^{-\beta}), \qquad 0 < x < \varepsilon^\beta,$$
$$= \varepsilon^{-2\alpha}c_+(x\varepsilon^{-\beta}), \qquad x > \varepsilon^\beta,$$

where $c_-\geq 0$ and $c_+>0$ are suitable functions defined in $(0,1)$ and $(1,\infty)$, respectively. Using simple transformations, the author reduces the problem to a similar problem discussed in her earlier paper [A. M. Guseinbekova, Izv. Akad. Nauk Azerbaĭdžan. SSR Ser. Fiz.-Mat. Tehn. Nauk **1960**, no. 6, 49–67; MR **24** #A2701].

J. Král (Prague)

Titchmarsh, E. C. 3713

On the relation between the eigenvalues in relativistic and non-relativistic quantum mechanics. II.

Quart. J. Math. Oxford Ser. (2) **15** (1964), 193–207.

Part I appeared in Proc. Roy. Soc. Ser. A **266** (1962), 33–46 [MR **24** #A1447]. In Dirac's equation for the quantum mechanics of a particle, assume the vector potential to be zero and the scalar potential V to be a function of the radial coordinate r alone. If $V(r)\to\infty$ as $r\to\infty$ (details are worked out only for $V(r)=r^2$), the spectrum is purely continuous. However, it is "almost discrete" at those points ("resonances") which are actually discrete in the corresponding non-relativistic case. In this posthumous paper the author shows that the resolvent of the relativistic operator, analytically continued across the spectrum as a cut, has non-real poles near these points. The difference between such a pole and the corresponding non-relativistic eigenvalue is $O(c^{-2})$, where c is the velocity of light.

J. M. Cook (Argonne, Ill.)

Sahnovič, L. A. 3714

Analytic properties of the discrete spectrum of the Schrödinger equation. (Russian)

Mat. Sb. (*N.S.*) **64** (**106**) (1964), 185–204.

In the present paper the author studies the Schrödinger equation (radial)

$$(1) \qquad \frac{d^2R}{dr^2}+\frac{2}{r}\frac{dR}{dr}+\left[2E+\frac{2A}{r}-\frac{l(l+1)}{r^2}-V(r)\right]R = 0,$$

where the potential is a superposition of the power potentials r^{-t} $(1<t<2)$.

The function studied in detail is

$$C(\varepsilon,\mu) = \lim_{r\to\infty} R(\varepsilon,\mu,r)e^{-\varepsilon r}r^{A/\varepsilon+1},$$

where $\mu=l+1$, $\varepsilon=\sqrt{(-2E)}$ $(\mathrm{Re}\,\varepsilon>0)$, $R(\varepsilon,\mu,r)$ being the solution of (1) such that

$$\lim_{r\to\varepsilon}\frac{R(\varepsilon,\mu,r)}{r^{\mu-1}} = 1.$$

The function $C(\varepsilon,\mu)$ can be continued analytically from the half-plane $\mathrm{Re}\,\varepsilon>0$ to the entire ε-plane with a cut along the line $\varepsilon=iy$ $(y\geq 0)$. The present paper is restricted to the study of the discrete spectrum of (1), taking $A>0$ for this. The possibility of continuing analytically the eigenvalues as functions of μ is considered, whence it is shown to follow that these functions of μ are uniquely determined by their values at integral points $\mu=1,2,\cdots$. Some of the results of this paper were given without proof in an earlier note by the author [Dokl. Akad. Nauk SSSR **152** (1963), 286–289; MR **29** #301].

Grobman, D. M. 3716

Asymptotic behaviour of almost linear systems of differential equations. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 774–776.

The author extends and makes more precise earlier work [same Dokl. **86** (1952), 19–22; MR **14**, 274] concerning the asymptotic equivalence of solutions of the systems (1) $x'=Ax+F(t,x)$ and (2) $y'=Ay$, where $F(t,0)=0$ and F satisfies a Lipschitz condition in x with Lipschitz "constant" $g(t)$. Solutions $x(t)$ and $y(t)$ of (1) and (2), respectively, are said to be analogous if $|x(t)-y(t)|\,|y(t)|^{-1}$ converges to 0 as $t\to\infty$. Theorem: Let $\int_{t_0}^{\infty}e^{\alpha\tau}\tau^\beta g(\tau)\,d\tau<\infty$ for some constant β and positive constant α. Then there is a homeomorphism Φ of the x-space onto the y-space such that Φ and Φ^{-1} satisfy a Lipschitz condition and such that for large enough t^*, the solution of (1) passing through a given point x^0 of the x-space at $t=t^*$ is analogous to the solution of (2) passing through Φx^0 at $t=t^*$. Moreover, the deviation of these two solutions is $O(e^{-\alpha t}t^{m-\beta})$, where m is a certain integer. A second similar theorem is stated and two examples are given illustrating the force of the hypothesis on the integral. No proofs are given.

Letter to the editor concerning the paper of N. F. Otrokov, "Multiple limit cycles". (Russian)

Mat. Sb. (N.S.) **64 (106)** (1964), 140–144.

In a paper by Otrokov [Mat. Sb. (N.S.) **41 (83)** (1957), 417–430; MR **19**, 278] there was discussed the question of the generation of limit-cycles from a multiple limit-cycle of a structurally stable planar system $\dot{x}=P(x,y)$, $\dot{y}=Q(x,y)$. Lemma 2 of that paper played an important role in the argument. The present author shows by an example that this lemma is incorrect. {References: Otrokov [Vestnik Leningrad. Univ. **16** (1961), no. 19, 23–44; MR **25** #4181], Andronov and Leontovič [Mat. Sb. (N.S.) **40 (82)** (1956), 179–224; MR **19**, 36], Neĭmark [Izv. Vysš. Učebn. Zaved. Leighton, Walter 3718

Behavior of solutions of a linear differential equation of second order.

Proc. Nat. Acad. Sci. U.S.A. **52** (1964), 830–832.

In this paper an affirmative answer is given to the question of whether or not all solutions of the equation (1) $y''+p(x)y=0$ tend to zero as $x\to\infty$ if $p(x)\to\infty$ as $x\to\infty$. The following theorem is proved. If $p(x)$ is of class C' and nondecreasing on the interval $I: x_0\leq x<\infty$, and if $p(x)\to\infty$ as $x\to\infty$, every solution of (1) tends to zero as $x\to\infty$. By a change of the independent variable in the equation (2) $(r(x)y')'+p(x)y=0$, the following corollary is obtained. If $r(x)$ and $p(x)$ are of class C' on the interval $I: x_0\leq x<\infty$, with $r(x)>0$ there, if $r(x)p(x)$ is nondecreasing on I, $r(x)p(x)\to\infty$ as $x\to\infty$, and if $\int_{x_0}^{\infty} dx/r(x)=\infty$, then every solution of (2) tends to zero as $x\to\infty$.

An outline of the theorem's proof is as follows. Introducing $u(x)=(y_1^2(x)+y_2^2(x))^{1/2}$, where y_1 and y_2 are linearly independent solutions of (1), and noting that one can write $y_1=u\sin v$, $y_2=u\cos v$, where $v'=k^2/u^2$ ($k=$ const), it is observed that y_1 and y_2 lie between the curves u and $-u$ and are tangent to them. The assumption that $u\geq m$, m an arbitrary positive constant, is shown to contradict Osgood's theorem concerning the monotonic decrease of the relative maxima of any solution of (1) as $x\to\infty$ [cf. Osgood, Bull. Amer. Math. Soc. **25** (1919), 216–221]. For the remaining case, in which u continually rises above and falls below the value m, an analysis (which again uses the Osgood theorem) shows that u may be made arbitrarily small as $x\to\infty$.

Chen, Xiang-yan [Chen, Hsiang-yen] 3719

Periodic solutions and limit cycles of differential equations containing a parameter.

Acta Math. Sinica **13** (1963), 607–619 (*Chinese*); *translated as Chinese Math.* **4** (1964), 661–674.

In the second-order system

$$(*)\qquad \dot{x}=P(x,y,\alpha),\qquad \dot{y}=Q(x,y,\alpha)$$

let the functions P, Q be continuous and have partial derivatives of any order required for all $(x,y,\alpha)\in R\times I$, where R is a region in the (x,y)-plane and I an interval of variation of α having $\alpha=0$ as an interior point. Assume that for $\alpha=0$ the system (*) has the periodic solution $L_0: x=x_0(t)$, $y=y_0(t)$. The paper is specifically directed to the search for the conditions for the non-vanishing of L_0 when the parameter α in (*) is slightly varied. In the special case where L_0 is a limit cycle and (*) a rotating vector field this problem has been investigated by Duff [Ann. of Math. (2) **57** (1953), 15–31; MR **14**, 751] and subsequently generalized by Seifert [*Contributions to the theory of non-linear oscillations*, Vol. IV, pp. 125–139, Princeton Univ. Press, Princeton, N.J., 1958; MR **21** #4278], Urabe [J. Sci. Hiroshima Univ. Ser. A **18** (1954), 183–219; MR **17**, 264] and others. In the paper under review the author considers the two cases: (i) L_0 a limit cycle, and (ii) L_0 lying in a periodic annulus. For the case (i) he obtains results which generalize those of Duff and Seifert mentioned above. For the case (ii) his results generalize those of Malkin [*Some problems of the theory of nonlinear oscillations* (Russian), GITTL, Moscow, 1956; MR **18**, 396], Pontrjagin [Ž. Èksper. Teoret. Fiz. **4** (1934), 883–885] and Zhang Zhi-fen [Degree Thesis, Moskow Univ., Moscow, 1957 (unpublished)]. The precise statements are too involved to be reproduced here.

Yamaguchi, Mikiko 3721

On the existence of a periodic solution for a certain nonlinear equation. (Japanese)

Sûgaku **15** (1963/64), 165–167.

The author proves that the conditions $C>AB$, $A-(AB/C)D<0$ and $A-\{1-(AB/C)\}D<0$ are sufficient for the existence of stable periodic solutions of the system of two differential equations

$$dx/dt = -A(x+B)+C(1-y)+Dy^*x,\qquad dy/dt = y^*x,$$

where A, B, C, D are positive constants and y^* is the function which is defined for all x and $0<y<1$ by $y^*=y$ $(x\leq 0)$ and $=1-y$ $(x\geq 0)$. If $A=2$, $B=375$, $C=2000$, and $D=20$, the author's sufficient conditions are satisfied. This special case is studied first and then the general case is studied. These sufficient conditions guarantee the existence of an unstable critical point around which we can construct a ring-shaped region R so that no solution starting from a point of R may not leave R. The uniqueness of periodic solutions is not discussed.

Previously, in connection with the study of electrochemical oscillations, U. F. Franck and R. FitzHugh [Z. Electrochemie **65** (1961), 156–168] treated the same problem by the use of analogue computers. The motivation of the present paper is to give a rigorous proof to this previous result.

On non-oscillatory solutions of the equation

$$u'' + a(t)|u|^n \operatorname{sign} u = 0.$$

(Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **35** (1964), 15–22.

Der Verfasser untersucht die angegebene Differentialgleichung, wobei $n>1$ und die Funktion $a(t)$ nichtnegativ und in jedem endlichen Teilintervall der Halbachse $t\geq 0$ summierbar sei. Er setzt sich das Ziel, Funktionsklassen $a(t)$ zu suchen, für die alle Lösungen $u(t)$ der Gleichung nichtoszillatorisch sind. Z.B. werden folgende Sätze bewiesen: (1) Die Gleichung besitzt dann und nur dann Lösungen $u_i(t)$, $i=1, 2$, für die $u_i(t)\sim c_i t^{i-1}$, $c_i\neq 0$ gilt, wenn $\int_0^\infty t^n a(t)\,dt<\infty$ ist. (2) Jede nicht-triviale Lösung genügt der Beziehung $u(t)\sim c_1+c_2 t$, $c_1^2+c_2^2>0$, wenn $a(t)$ eine absolutstetige, positive Funktion ist und

$$\int_0^\infty t^n a(t) \exp\left\{\frac{n-1}{4}\int_0^t [|a'(\tau)|+a'(\tau)]\,d\tau\right\} dt < \infty$$

gilt. Zwei weitere Sätze beruhen auf komplizierteren Koeffizientenbedingungen. *R. Reissig* (Berlin)

Extension des théorèmes de Liapounoff et de Chetayev relatifs à la stabilité.

C. R. Acad. Sci. Paris **259** (1964), 38–41.

Take an n-vector system

$$(1)\qquad \dot{x} = X(x, t), \qquad X(0, t) = 0, \qquad 0 \leq t \leq T,$$

and let Ω be the set $\|x\|\leq a$, $t\in[0, T]$. It is assumed that standard existence and unicity properties hold in Ω. Let also $0\leq\alpha<\beta$. Definition of (α, β, T) practical stability: It holds if there exists $\lambda\in[\alpha, \beta]$ such that if $x_0=x(0)$ and $\|x_0\|<\lambda$, then $\|x(t)\|<\beta$ for $t\in[0, T]$.

One defines as usual the Liapunov function $V(x, t)$ as positive definite if there exists $W(x)$, continuous and positive in $\|x\|<a$, such that $W\leq V$ in Ω. Theorem (Generalized Liapunov stability): The solutions of (1) are (α, β, T) practically stable if there exists $V(x, t)$, $W(x)$ such that $\sup(V|\ \|x\|\leq\lambda)<\inf(W|\ \|x\|=\beta)$, this for some $\lambda\in[\alpha, \beta]$. A somewhat complicated extension of Četaev's instability theorem is also given. *S. Lefschetz* (Princeton, N.J.)

Brauer, Fred 3728

Nonlinear differential equations with forcing terms.

Proc. Amer. Math. Soc. **15** (1964), 758–765.

The basic problem is the comparison of the solutions of the linear equations $x'=Ax+p(t)$ and $y'=Ay+f(t, y)+p(t)$, where x, p, y, f are vectors and A is a square matrix. The author seeks conditions under which $y\to x$ as $t\to\infty$. This is a strong result, and, as might be expected, requires a strong condition on f: $\int_0^\infty (|f|/|y|)\,dt<\infty$.

Conditions that x and y tend to 0 as $t\to\infty$ are given, and are of the usual form. Conditions are also given that $|y|$ be below a certain bound for $0\leq t<\infty$. *E. Pinney* (Berkeley, Calif.)

On the asymptotic theory of relaxation oscillations in systems with one degree of freedom. II. Calculation of the period of the limit cycle. (Russian. English summary)

Vestnik Moskov. Univ. Ser. I Mat. Meh. **1964**, *no.* **3**, 56–65.

Author's summary: "This is a continuation of the paper published in the previous issue of this journal [same Vestnik **1964**, no. 2, 70–82; MR **29** #333]. As is known, under certain conditions in the system $\varepsilon\dot{x}=f(x, y)$, $\dot{y}=g(x, y)$, where ε is a small positive parameter, there may occur periodic oscillations that are close to discontinuous. The author assumes the presence of an irregular point of order $m>2$ on the curve $f(x, y)=0$. Under this assumption, an asymptotic formula to quantities of the order $O(\varepsilon^{(3m)/(2m-1)})$ is obtained for the period T_ε of the limit cycle Z_ε (that is, close to a discontinuous periodic solution Z_0). This formula permits an estimate to be made of the period without integrating the system of differential equations. It is found, in particular, that the difference between the period T_ε and the period T_0 of the discontinuous solution Z_0 has the order $O(\varepsilon^{n/(2n-1)})+O(\varepsilon^{(k+1)/(2k-1)})$, where n is maximal even, and k is maximal odd order of irregular points on the solution Z_0." *R. Conti* (Florence)

Aeppli, A.; Markus, L. 3730

Sur l'équivalence des systèmes différentiels.

Ann. Inst. Fourier (Grenoble) **14** (1964), *fasc.* 1, 83–86.

This short paper is principally a summary of known results about the equivalence (up to homotopy or homeomorphy) of line element fields on the two-dimensional torus. One new result states that, in most circumstances, if two systems are homotopic, they may be joined by a path in the space of systems containing only a finite number of bifurcation points. No indication of a proof is given. *R. L. Reinhart* (College Park, Md.)

Convergence in second-order dissipative systems. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **19** (1964), no. 1, 15–25.

In a previous paper [same Vestnik **18** (1963), no. 4, 14–26; MR **28** #1345] the author investigated the system

$$(1)\qquad \dot{x} = ax+f_2(y)+P(t), \qquad \dot{y} = f_1(x)+by+Q(t),$$

where the functions f_i are of class C^1. It was assumed that (2) $a+b<0$; (3) $ab-h_1(x)h_2(y)>\varepsilon(x)+\varepsilon(y)$, $h_i(z)=f_i(z)/z$, for $|x|>\bar{a}>0$, $|y|>\bar{b}>0$ and $\varepsilon(z)>0$ with $z\varepsilon(z)\to+\infty$ with z. It was shown that there exists a region Ω to which all solutions tend, remaining in it as $t\to+\infty$. Systems with such a property are said to be dissipative. For such systems, if P and Q have period ω, then (1) has a solution of the same period. The author is particularly interested in "convergent" systems, i.e., stable in the large. If $ab>0$, sufficient convergence conditions were found to be

$$(4)\qquad a+b < 0, \qquad ab-\sup|f_1'(x)|\cdot\sup|f_2'(y)| \geq 0.$$

Note that (4) will hold for the system (1) in which a, b are replaced by $\mu_1 a$, $\mu_2 b$ with $a, b<0$ and f_i satisfy (3) with the $\mu_i>0$ and such that $\mu_1\mu_2>-ab/(\sup|f_1(x)f_2(y)|)$, $(x, y)\in\Omega$. Similar results hold for $ab<0$, with Theorem 1: If (3) holds and $a+b=-K$, where $K>0$ and is bounded away from zero, then convergence takes place.

Analogous results are obtained for a system such as (1) with P, Q of the form $P(x, y, t)$, $Q(x, y, t)$ both bounded. Application is made to the Cartwright-Littlewood equation (5): $\ddot{x}+\mu f(x)\dot{x}+g(x)=\mu p(t)$ by the following theorem. Let $F(x)=\int_0^x f(x)\,dx$, $G(x)=\int_0^x g(x)\,dx$, $P(t)=\int_0^t p(t)\,dt$. Suppose (a) $f(x)>0$ and $g'(x)>0$ are continuous, and $|F(x)|$ and $G(x)\to\infty$ with $|x|$; (b) $p(t)$ is continuous with period ω and $P(t)$ is bounded; (c) $\mu>0$ and is bounded away from zero. Then the system (5) is convergent.

Brjuno, A. D. 3733

The normal form of differential equations. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1276–1279.

Theorem: There exists an invertible transformation $x=\xi(y)$ of the differential system $\dot{x}=\varphi(x)$ into the system $\dot{y}=\psi(y)$, where ξ, φ, and ψ are formal power series without free terms, $(\partial x_i/\partial y_j|_0)=(\lambda_i\delta_{ij})$, $\sum_k(\partial\xi_i/\partial y_k)\psi_k(y)=\varphi_i(\xi(y))$, $\psi_i(y)=y_i\sum_Q g_{iQ}y^Q$, $Q=(q_1,\cdots,q_n)$, $y^Q=y_1^{q_1}\cdots y_n^{q_n}$, $g_{iQ}\neq 0$ if and only if $\sum_i q_i\lambda_i=0$ and Q ranges over a certain subset of the integer lattice points of E^n. This theorem, stated, proved, and discussed in this paper, is the latest in a long series of results concerning the equivalence of differential systems beginning with Poincaré's thesis [Fac. Sci. Paris, Gauthier-Villars, Paris, 1879]. More recently Sternberg [Amer. J. Math. **79** (1957), 809–824; MR **20** #3335] and Chen [ibid. **85** (1963), 693–722; MR **28** #3224] have worked on similar problems.

C. S. Coleman (Claremont, Calif.)

Yoshizawa, Taro 3734

Extreme stability and almost periodic solutions of functional-differential equations.

Arch. Rational Mech. Anal. **17** (1964), 148–170.

The author combines the idea of using Ljapunov functions defined for pairs of solutions instead of single solutions, previously introduced by Hale [same Arch. **15** (1964), 289–304; MR **29** #1395] for ordinary differential equations, with his own work on functional-differential equations. He gives an appropriate definition of uniform-asymptotic stability and proves that if such stability obtains and certain boundedness conditions are satisfied, there exists a Ljapunov function with the desired properties, including a negative-definite "total derivative" along the pair of solutions envisaged. This existence theorem is then applied to prove the existence and local uniqueness of almost periodic solutions of almost periodic functional-differential equations. The precise statements of the theorems are too complicated to reproduce here.

The standard method of successive approximations is adopted to establish an existence and a uniqueness theorem for the equation

$$(1)\qquad \phi(t) = \omega(t) \quad \text{for } t\leq 0;$$

$$\phi'(t) = \int_0^\infty f[t, \phi(t-s)]\,dr(t, s)+g(t) \quad \text{for } t\in[0, a], \quad s\geq 0.$$

The author claims an improvement over the result of A. Bielecki and M. Maksym [Folia Soc. Sci. Lublinensis **2** (1962), 74–78]. *N. P. Bhatia* (Cleveland, Ohio)

Dłotko, T.; Kuczma, M. 3736

Sur une équation différentielle fonctionnelle à argument accéléré.

Colloq. Math. **12** (1964), 107–114.

Let $H(t, x, y, z)$ be continuous and let $h(t)$ be continuous, where all the variables are real. Consider the differential

equation (1) $H(t, \varphi(t), \varphi(h(t)), \varphi'(t)) = 0$. Two special cases of (1) are considered, namely, (2) $\varphi(h(t)) = g(t, \varphi(t), \varphi'(t))$ and (3) $\varphi'(t) = f(t, \varphi(t), \varphi(h(t)))$. Assume that $h(t) \geq t$. The authors then give sufficient conditions so that the following two problems have a solution. (I) To find a function $\varphi(t)$ satisfying (2) in $a \leq t < b$ such that the initial condition, $\varphi(t) = \alpha(t)$ for $a \leq t \leq h(a)$, is satisfied. (II) To find a function $\varphi(t)$ satisfying (3) in $a \leq t \leq b$ (or $a \leq t < \infty$) such that the initial condition $\varphi(a) = \varphi_0$ is satisfied. The method of proof (for II) is to use the Schauder fixed-point theorem. {The authors do not observe that their theorems are true for systems where x, y, and z are in R^n.}

A one-sided bound for ordinary differential equations with time lag. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 853–856.

On traite le système différentiel "à retard" $dx/dt = f(t, x_t)$ sous la forme vectorielle. Trois théorèmes concernent le prolongement des solutions sur le demi-axe, et l'unicité aux estimations unilatérales. Les fonctionnelles spéciales sont définies et utilisées dans les inégalités différentielles. L'idée des estimations en question tire son origine de N. N. Krasovskiĭ. Un groupe suivant de travaux concerne les équations différentielles ordinaires (aussi dans l'espace de Banach).

Friedman, Avner 3738

A new proof and generalizations of the Cauchy-Kowalewski theorem.

Trans. Amer. Math. Soc. **98** (1961), 1–20.

The author gives a proof of the Cauchy-Kowalewski theorem by a method different from those already known. The proof is based on a priori bounds of the successive derivatives of a system under the hypothesis that these derivatives exist. Thus he constructs a solution in the form of power series in the corresponding variables. In the proof it is not necessary to reduce the system to one of first order. He also considers the Goursat problem (the case of several "time" variables) and also a mixed problem.

Simplifying the structure of second order partial differential equations.

Trans. Amer. Math. Soc. **99** (1961), 303–307.

Let D be a bounded or an unbounded region in Euclidean n-space with compact boundary. In the equation

$$(1) \qquad \Delta_2 A + cA = 0$$

let Δ_2 denote the Laplace-Beltrami operator describing a strong positive definite tensor. The author shows that, by a conformal mapping and a change of the unknown variable, equation (1) can be reduced to the form $\bar{\Delta}_2\bar{A} + c_0\bar{A} = 0$, where c_0 is a constant which can be taken to be 0 if $c > 0$. A similar result obtains for the corresponding parabolic equation whenever it is possible to set $c_0 = 0$ independently of the sign of c.

Gröbner, W. 3740

Lösung der allgemeinen partiellen Differentialgleichung 1. Ordnung mittels Lie-Reihen.

Monatsh. Math. **68** (1964), 113–124.

This paper is concerned with the solution of general first-order partial differential equations by using Lie-Reihen for integrating the associated characteristic differential equations. Three theorems are proven for a single partial differential equation; a fourth theorem deals with a pair of equations, and it is indicated that the methods could be extended to a system of equations. Although the functions occurring are commonly required to be holomorphic in the region under consideration, it is possible by this Lie-Reihen method to consider functions which are finitely differentiable.

Let G be a multiply connected domain of the (x_1, x_2)-plane and ω_ρ a Pfaffian whose coefficients depend on a function ρ and its derivatives $\partial\rho/\partial x_1$, $\partial\rho/\partial x_2$. The paper deals with the periods $\pi_k[\omega_\rho] = \int_{(\gamma)_k} \omega_\rho$ and their dependence with respect to the boundary values of ρ. The result is that, apart from the trivial case $\rho \equiv 0$, the function ρ does not vanish in the (closed) domain $\bar{G}$. Similarly, the existence of functions $\rho > 0$ with constant boundary values can be proved having a closed Pfaffian ω_ρ with periods arbitrarily prescribed. Finally, a multiplicator μ exists with constant boundary values which transforms the differential operator

$$\sum_{i,j} \frac{\partial}{\partial x_i}\left(a_{ij}\frac{\partial}{\partial x_j}\right) + \sum_k e_k \frac{\partial}{\partial x_k}$$

into Bianchi's canonical form. It follows that $\mu \neq 0$ in $\bar{G}$.

Kuks, L. M. 3742

On the oscillation of solutions of partial differential equations in complex regions. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1963**, 1279–1284.

The article is concerned with the existence of zeros of solutions w (or of some expressions depending on w) of $\partial^2 w/\partial z_1^2 + \partial^2 w/\partial z_2^2 + j(z_1, z_2) = 0$, where z_1, z_2 are complex variables and j is analytic. Results concerning elliptic equations with two real independent variables and ordinary differential equations in a complex independent variable are then obtained by specialization. The technique used is based upon integration by parts (Stokes's theorem).

The Dirichlet problem for a class of equations of degenerating elliptic type.

Acta Math. Sinica **12** (1962), 40–46 (*Chinese*); *translated as Chinese Math.* **3** (1963), 42–48.

Consider the equation

$$(*)\qquad M[u] = u_{xx}+y^m u_{yy}+au_x+bu_y+cu = 0,\qquad c\le 0,\ m\ge 1,$$

in a domain D in $y>0$ bounded by a segment γ of $y=0$ and a smooth curve τ in $y>0$. It is known that the Dirichlet problem in D can be solved if $b(x,0)<1$ when $m=1$, $b(x,0)\le 0$ when $1<m<2$, and $b(x,0)<0$ when $m\ge 2$. If these conditions are not satisfied, then one can specify data only on τ. If one can find a function Ω such that

$$\lim_{y\to 0}\,(b+2y^m\Omega_y/\Omega) \begin{cases} <1 & \text{if } m=1,\\ \le 0 & \text{if } 1<m<2,\\ <0 & \text{if } m\ge 2\end{cases}$$

with $M(\Omega)/\Omega<0$, then one can set $u=\Omega V$ and obtain a problem of the first type for V. u itself will then satisfy the modified Dirichlet problem $\lim_{(x,y)\to P} u/\Omega=\varphi$ for $P\in\gamma+\tau$. The author establishes the existence of Ω for all m with certain restrictions on b.

Aruffo, Giulio 3746

Sistemi ellittici di equazioni lineari del primo ordine in domini a connessione multipla.

Ricerche Mat. **13** (1964), 80–91.

Let $T\subset \mathbf{R}^n$ be bounded by an external $(n-1)$-cycle C and by p $(n-1)$-cycles γ_i interior to C. The problem is to find v such that

$$\sum_{i,k}\frac{\partial}{\partial x_i}\left(a_{ik}\frac{\partial v}{\partial x_k}\right) = -\sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i}$$

with $\int_{\gamma_i}\omega_{n-1}=0$, where $\sum a_{ik}(x)\xi_i\xi_k$ is positive definite and

$$\omega_{n-1} = \sum_i(-1)^i\left(f_i+\sum_k a_{ik}\frac{\partial v}{\partial x_k}\right)dx_1\wedge\cdots\wedge\widehat{dx_i}\wedge\cdots\wedge dx_n.$$

It is shown that if $g, g_1, \cdots, g_p$ are suitable functions given on $C, \gamma_1, \cdots, \gamma_p$, then in a suitable function space there exists a unique solution of the problem satisfying the conditions of taking on C the value g and taking values on γ_i such that $v-g_i=\lambda_i$ with the constants λ_i arbitrary (not determined). The solution v of the homogeneous problem is found in the subspace V of $H'(T)$ consisting of functions v such that $v=0$ on C, $v=\lambda_i$ on γ_i (λ_i arbitrary), and the region T is supposed to be such that $\|v\|=\sum_1^n(\int_T(\partial v/\partial x_i)^2\,dx)^{1/2}$ is a norm equivalent to the $H'(T)$ norm.

A bounded domain Ω in R^m is in $H_{\delta,\beta}$ ($\delta>0$, $0<\beta<\pi/2$) if for each $x^0\in\partial\Omega$ there exists a cone with vertex x^0 of angular opening $\pi/2-\beta$ and height δ which lies outside Ω. Let $n(x^0)$ be the unit vector penetrating Ω in the direction of the axis of the cone. Let $d(x)=\operatorname{dist}(x,\partial\Omega)$ and set $T(x^0,t)=\{x\in\Omega: t|x-x^0|<d(x)\}$, $x^0\in\partial\Omega$, $0<t<1$. Let $\gamma(t)$ be the supremum of the angles between the vectors $x-x^0$ and $n(x^0)$ for all $x\in T(x^0,t)$. It follows that $\gamma(t)\le\beta+\arccos t$ for t close to 1. Let $\Omega_1=\{x\in\Omega: d(x)<\delta_1\}$, $0<\delta_1<\delta$.

Let $u\in C^2(\Omega)\cap C(\Omega^-)$ be a solution of the uniformly elliptic equation $\sum A_{ij}(x)u_{x_ix_j}+\sum B_i(x)u_{x_i}+C(x)u=f(x)$, where $0<\alpha\le\sum A_{ij}(x)\xi_i\xi_j\le 1$, $|\xi|=1$. Let $B(x)$ be the vector $(B_1(x),\cdots,B_m(x))$ and assume that the lower-order coefficients satisfy for all $x^0\in\partial\Omega$ the relations: (i) $d(x)|\langle n(x^0),B(x)\rangle|\le 8^{-1}\alpha(1-\lambda)$, $x\in T(x^0,\frac12)\cap\Omega_1$; (ii) $d(x)|B(x)|\le K$ and $|C(x)|d(x)^{2-\lambda}\delta_1^{\lambda}\le K_1$, $x\in\Omega_1$; (iii) $d(x)|B(x)|\le 3\alpha(1-\lambda)/16$ and $|C(x)|d(x)^2\le K_1$, $x\in\Omega-\Omega_1$, where $0<\lambda<1$ and $K_1=2^{-4-\lambda}\alpha\lambda(1-\lambda)$. Let $|u(x^1)-u(x^0)|\le h|x^1-x^0|^{\lambda}$ for $x^0, x^1\in\partial\Omega$. Let

$$F=\sup\{d(x)^{2-\lambda}|f(x)|: x\in\Omega\}$$

and $U=\sup\{|u(x^0)|: x^0\in\partial\Omega\}$. Then there exists $\beta^*>0$ such that if Ω is in $H_{\delta,\beta}$ for $\beta\le\beta^*$, $|u(x)-u(x^0)|\le\tau(h+F+K_1\delta_1^{-\lambda}U)|x-x^0|^{\lambda}$ for $x\in\Omega$, $x^0\in\partial\Omega$, where β^* and τ depend only on α, K, λ, m, and δ.

n a bounded domain Ω with sufficiently smooth boundary ' the author considers the equation

$$Lu = -\sum_{i=1}^{n} \frac{\partial}{\partial x_i} a_i(x, u, p) + b(x, u, p) = f(x),$$

$$x = (x_1, \cdots, x_n) \in \Omega,$$

$= (p_1, \cdots, p_n)$, $p_i = \partial u/\partial x_i$, where $\sum_{ij} \partial a_i \xi_i \xi_j/\partial p_j \geq m \sum_i \xi_i^2$. 'or $u, \Phi \in W_2^1(\Omega)$ put

$$[Lu, \Phi] = \sum_i \int_\Omega a_i \frac{\partial \Phi}{\partial x_i} d\Omega + \int_\Omega b\Phi \, d\Omega$$

nd suppose that

A) $$[Lu - Lv, u - v] \geq \gamma \sum_i \|\partial(u-v)/\partial x_i\|_{L_2}^2,$$

B) $$[Lu - Lv, \Phi] \leq C\|u - v\|_{W_2^1} \|\Phi\|_{W_2^1}$$

or every $u, v, \Phi \in W_2^1$. Assume $f = f_1 - \sum_i \partial f_{2i}/\partial x_i$, with $_1, f_{2i} \in L_2$, then for the boundary-value problem $Lu = f$, $u|_\Gamma = 0$ there exists a unique generalized solution in $\overset{\circ}{W}{}_2^1$, nd an estimate is given for it. The proof is an application f the continuation method to the problem $-\gamma \Delta u + \lambda(Lu + \gamma \Delta u) = f$, $u|_\Gamma = 0$, $0 \leq \lambda \leq 1$. For equations of the orm

$$Lu = -\sum_{ij} \frac{\partial}{\partial x_i} (a_{ij}(x, u, p)p_j) + b(x, u, p) = f,$$

vith $\gamma \sum_i \xi_i^2 \leq \sum_{ij} a_{ij} \xi_i \xi_j \leq C \sum_i \xi_i^2$ the author considers lso the second boundary-value problem

$$Lu = f, \quad f \in L_2, \quad \sum_{ij} a_{ij} p_i \cos(\nu, x) + \sigma u|_\Gamma = 0.$$

Jnder the conditions (A), (B) and $\sigma \geq 0$, $\sigma \not\equiv 0$, he proves he existence and uniqueness of a generalized solution of his problem and gives an estimate for it. Same results for $\sigma \equiv 0$ if the condition (A) is replaced by

A') $$[Lu - Lv, u - v] \geq \gamma \|u - v\|_{W_2^1}^2.$$

'he approach is the same followed for the first problem. 'he author applies his results to the non-linear problem f plasticity. *L. Cattabriga* (Zbl 107, 306)

lrowder, Felix E. 3750

Variational boundary value problems for quasi-linear elliptic equations of arbitrary order.

Proc. Nat. Acad. Sci. U.S.A. **50** (1963), 31–37.

.et $H^m(\Omega)$ be the Hilbert space of (classes of) L^2 functions n the open subset Ω of R^n whose derivatives of order $\leq m$, in the distributions sense, belong to $L^2(\Omega)$; let $H_0^m(\Omega)$ be the closure of $C_0^\infty(\Omega)$ in $H(\Omega)$; $\| \|_m$ is the norm n $H^m(\Omega)$. Consider the form on $H^m(\Omega) \times H^m(\Omega)$, antilinear n v but non-linear in u,

$$a(u, v) = \sum_{|\alpha|, |\beta| \leq m} (a_{\alpha\beta}(x, u, \cdots, D^m u) D^\alpha u, D^\beta v)_{L^2}.$$

'he "coefficients" $a_{\alpha\beta}$ are continuous functions of all heir arguments and, for u in a bounded subset of $H^m(\Omega)$, they remain in a bounded subset of $L^\infty(\Omega)$. The crucial assumption is then the following:

$$\mathrm{Re}[a(u, u - u_1) - a(u_1, u - u_1)] \geq$$
$$g(\sup(\|u\|_m, \|u_1\|_m))\|u - u_1\|_m^2,$$

where $g(t)$ is a non-decreasing function in $1 < t < \infty$ such that $\int_1^\infty g(t)\,dt = +\infty$, and u, u_1 are arbitrary elements of a closed subspace V of $H^m(\Omega)$. As usual, V contains $H_0^m(\Omega)$.

The main result of the paper is then the following: Under the above assumptions, for every $f \in L^2(\Omega)$, there is a unique element $u \in V$ such that $a(u, v) = (f, v)_{L^2}$ for all $v \in V$.

The main tool in the proof is the following result of non-linear functional analysis. Let H be a Hilbert space, D an open subset of H, G a (non-linear) mapping of D into H such that, for any strongly convergent sequence $u_k \to u$ in D, $G(u_k) \to G(u)$ weakly in H, and such that, for some constant $c > 0$,

$$\mathrm{Re}(G(u) - G(u_1), u - u_1) \geq c(u - u_1, u - u_1),$$

where (,) is the inner product in H. Then the image of D under G is open. *F. Treves* (New York)

Browder, Felix E. 3751

Variational boundary value problems for quasi-linear elliptic equations. II.

Proc. Nat. Acad. Sci. U.S.A. **50** (1963), 592–598.

This paper improves and extends the results presented in an article previously reviewed [#3750 above]. The operators studied this time are of the form

$$Au = \sum_{|\alpha| \leq m} D^\alpha [A_\alpha(x, u, Du, \cdots, D^m u)].$$

A suitable assumption is made so as to insure that $A_\alpha(x, u, \cdots, D^m u) \in L^2(\Omega)$ for each $u \in H^m(\Omega)$ (Ω is the region in R^n where the boundary-value problem is posed). The generalized Dirichlet form $a(u, v)$ associated with A is supposed to satisfy a condition

$$\mathrm{Re}[a(u, u - u_1) - a(u_1, u - u_1)] \geq$$
$$c(\sup(\|u\|_m, \|u_1\|_m))\{\|u - u_1\|_m^2$$
$$-k\|u - u_1\|_{m-1}\|u - u_1\|_m\} - k\|u - u_1\|_{m-1}^2,$$

with $k \geq 0$, $c(r) > 0$ non-increasing such that $\int_1^\infty c(r)\,dr = +\infty$. This replaces the positivity assumption of Part I. The reasonings are based on arguments of functional analysis in Hilbert spaces and make use of the notion of "hemi-continuity", introduced here by the author. In Part I, the mappings considered, from an open subset of a Hilbert space H into H, were continuous from strong topology into weak topology on H. Now, it is only required that their restriction to any line segment be continuous (the space of values H still being equipped with the weak topology). Various existence and uniqueness theorems are obtained (for the weak solution to the boundary-value problem). *F. Treves* (New York)

Browder, Felix E. 3752

Variational boundary value problems for quasi-linear elliptic equations. III.

Proc. Nat. Acad. Sci. U.S.A. **50** (1963), 794–798.

The same operators, as in Part II [#3751 above], are

studied, but the basic assumption on the Dirichlet form associated with the operator is replaced by the following:

$$\operatorname{Re}[a(u, u-u_1)-a(u_1, u-u_1)] \geq -k\|u-u_1\|_{m-1}^2.$$

Then an existence theorem can be proved, but the author does not prove uniqueness (for the weak solution to the boundary-value problem associated with the form $a(u, v)$). The functional analysis arguments make use of the notion of hemicontinuity, introduced in Part II.

F. Treves (New York)

Vaghi, Carla 3753

Soluzioni C-quasi-periodiche dell'equazione non omogenea delle onde.

Ricerche Mat. **12** (1963), 195–215.

Let Ω be a bounded domain of the n-dimensional Euclidean space, normal with respect to the Dirichlet problem. (A domain is called normal if the Dirichlet problem for Laplace's equation is solvable for any continuous boundary function.) The author considers for the hyperbolic equation

$$\frac{\partial^2 u}{\partial t^2} = Au+f(x,t) \qquad (x \in \Omega,\ 0 \leqq t \leqq l)$$

the following mixed boundary-value problem:

$$u(x,0) = \varphi(x), \qquad u_t(x,0) = \psi(x) \qquad (x \in \Omega),$$

$$u(x,t)|_{x\in\partial\Omega} = 0 \qquad (\partial\Omega = \text{boundary of } \Omega).$$

A is the operator $Au = \sum_{i,j}^{1,\cdots,n} \partial(a_{ij}(x)\partial u/\partial x_j)/\partial x_i - a(x)u$, whose coefficients are real, measurable and bounded in Ω. Further,

$$a_{ij}(x) = a_{ji}(x), \qquad a(x) \geqq 0,$$

$$\sum_{i,j}^{1,\cdots,n} a_{ij}(x)\xi_i\xi_j \geqq \nu \sum_{i=1}^n \xi_i^2 \qquad (\nu = \text{const} > 0).$$

Il'in [Uspehi Mat. Nauk **15** (1960), no. 2 (92), 97–154; MR **22** #9721] has given conditions on the operator A and the functions f, φ, ψ in order that the above mixed problem be solvable in the classical sense. On the other hand, Amerio [Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **28** (1960), 147–152; ibid. (8) **28** (1960), 322–327; ibid. (8) **28** (1960), 461–466; MR **22** #6927] has obtained for the wave equation results about the almost periodicity of generalized solutions of the mixed boundary-value problem, assuming that $f(x,t)$ is almost periodic. Using these results of Il'in and Amerio, the author obtains conditions (generalizing those given by Il'in) on the operator A and the functions f, φ, ψ so that, for $f(x,t)$ almost periodic, the above boundary-value problem has a classical solution $u(x,t)$, which, together with $u_t(x,t)$ and $u_{tt}(x,t)$, is $C_{\bar\Omega}$ almost periodic (a function $v(x,t)$ is called $C_{\bar\Omega}$ almost periodic if it is almost periodic with respect to t and continuous with respect to $x \in \bar\Omega$). Likewise, it is proved that if Ω' is a domain such that $\bar\Omega' \subset \Omega$, then the functions $u_{x_i}(x,t)$, $u_{x_i t}(x,t)$ and $u_{x_i x_j}(x,t)$ (and hence the derivatives of first and second order with respect to all the variables) are $C_{\bar\Omega'}$ almost periodic.

Sur le problème de Dirichlet pour l'équation $\Delta U = \varphi(U)$.

C. R. Acad. Sci. Paris **251** (1960), 26–28.

L'auteur cherche dans l'intérieur D d'un contour plan C la solution $u = u(x,y) = u(z)$ du problème (1) $\Delta u = \varphi(u)$, $u^* = \psi(s)$ où Δ est le laplacien, $\varphi(u)$ est une série entière $\varphi(u) = a_0 + a_1 u + \cdots$ absolument convergente sur $|u| < R$, u^* est la valeur de u sur C et $\psi(s)$ est une fonction continue de l'arc s de C. Le problème modifié suivant (2) $\Delta u = \lambda\varphi(u)$, $u^* = \lambda\varphi(s)$ équivaut à la résolution de l'équation intégrale (3) $u(z) = -(\lambda/2\pi)\iint_D g(z,\zeta)\varphi[u(\zeta)]\,d\sigma + \lambda v(z)$ où $g(z,\zeta)$ est la fonction de Green du domaine D et $v(z)$ est la solution du problème de Dirichlet $\Delta v = 0$, $v^* = \psi(s)$. Cherchons les solutions analytiques en λ, $u = u_0 + \lambda u_1 + \lambda^2 u_2 + \cdots$ de l'équation (3). Puisque celle qui correspond à $\lambda = 0$ est nulle, on a (4) $u = \sum_{n=1}^\infty \lambda^n u_n$ et par suite pour $p = 1, 2, \cdots$ et $\alpha_k = 1, 2, \cdots$,

$$u^p = \sum_{n=p}^\infty \lambda^n s_n^{(p)}, \qquad \text{où } s_n^{(p)} = \sum_{\alpha_1+\cdots+\alpha_p = n} u_{\alpha_1}u_{\alpha_2}\cdots u_{\alpha_p}.$$

En portant la série $\varphi(u) = a_0 + \sum_{n=1}^\infty \lambda^n \sum_{p=1}^n a_p s_n^{(p)}$ dans l'équation (3) on trouve les formules

$$u_1 = -\frac{a_0}{2\pi}\iint_D g(z,\zeta)\,d\sigma + v(z),$$

$$u_{n+1} = -\frac{1}{2\pi}\iint_D g(z,\zeta)\sum_{p=1}^n a_p s_n^{(p)}(\zeta)\,d\sigma$$

pour les termes de la solution (4). La suite de la note est consacrée à l'étude de la validité de la solution formelle (4) se réduisant dans le cas $\lambda = 1$ à la solution du problème (1). *F. Leja* (Zbl 95, 83)

Jakubov, S. Ja. 3758
Investigation of the Cauchy problem for evolution equations of hyperbolic type. (Russian. Azerbaijani summary)
Akad. Nauk Azerbaĭdžan. SSR Dokl. **20** (1964), no. 4, 3–6.

The equation $u''+Au=f(t,u)$ with $u(0)=u_0$, $u'(0)=u_1$ is considered, where $t\to u(t)$ takes values in a Banach space and A is a closed operator. One requires solutions to be twice continuously differentiable on $[0,T]$ with Au and $A^{1/2}u'$ continuous. Some standard results for first-order equations are invoked to obtain existence and uniqueness theorems under suitable, frequently used types of hypotheses. *R. Carroll* (Urbana, Ill.)

Mamedov, Ja. D. 3759
Some properties of the solutions of non-linear equations of hyperbolic type in Hilbert space. (Russian)
Dokl. Akad. Nauk SSSR **158** (1964), 45–48.

The author considers equations of the form $y''+A(t)y+B[t,y']+P(t,y)=0$ and $x''+A(t)x+P(t,x)=0$, where $A(t)$ is a self-adjoint positive operator in a real Hilbert space H, $D(A(t))$ is independent of t, $t\to A(t)$ is strongly differentiable, $(A'(t)x,x)\le\alpha(t)(A(t)x,x)$, $B[t,\cdot]$ is an unbounded operator with $(B[t,x],x)\ge-\frac{1}{2}\alpha(t)\|x\|^2$ for $x\in D(B)$, and $(P(t,x),h)=\lim(1/\lambda)(F(t,x+\lambda h)-F(t,x))$ for $x\in D(A^{1/2})$ defines P, where F is suitable. If F_t exists with $F_t(t,x)\le\alpha(t)F(t,x)$ $(x\in D(A^{1/2}))$, then for $x(0)$, $y(0)$ in $D(A^{1/2}(0))$ estimates are obtained, for example, of the form

$$\|y'\|^2+\|A^{1/2}(t)y\|^2+2F(t,y)\le$$
$$\left(\|y(0)\|^2+\|A^{1/2}(0)y(0)\|^2+2F(0,y(0))\right)\exp\left(\int_0^t\alpha(s)\,ds\right)$$

and various consequences are derived. Then $x''+A(t)x=f(t,x)$ is considered, where $\|f(t,x)-f(t,y)\|\le k(t,r)\|A^{1/2}(t)(x-y)\|$ when $x,y\in S_r$, $S_r=(x:\|A^{1/2}x\|\le r)$ with $\int_0^\infty k(t,r)\,dt<\infty$ and $A(t)$ is as above. For $x_0-y_0\in D(A^{1/2}(0))$ it is asserted that

$$\|x(t)-y(t)\|_E\le c\|x(0)-y(0)\|\exp\left(\int_0^t|\alpha(s)|\,ds\right),$$

where $\|x\|_E=\|x'(t)\|+\|A^{1/2}(t)x(t)\|$, and applications are indicated. Existence questions are then treated under various hypotheses for the above equations. *R. Carroll* (Urbana, Ill.)

On the uniqueness of the generalized solution of the Cauchy problem for a hyperbolic system of two quasi-linear equations. (Russian. English summary)
Vestnik Moskov. Univ. Ser. I Mat. Meh. **1964**, no. 4, 3–6.

Ces deux notes considèrent le système:

$$\frac{\partial u_i}{\partial t}+\frac{\partial\varphi_i(u,t,x)}{\partial x}=f_i(u,t,x),$$

où φ est deux fois, et f, une fois, continûment dérivable sur $W=K\times[0,T]\times\mathbf{R}$ (K convexe et borné). Le système vérifie sur W une condition d'hyperbolicité un peu plus forte que le fait que les valeurs propres de la matrice d'éléments $\partial\varphi_i/\partial u_k$ sont réelles et distinctes.

Dans la première note, les auteurs démontrent l'unicité pour le problème de Cauchy en ce qui concerne les solutions continûment différentiables par morceaux, restant dans K, à dérivées localement bornées et vérifiant une condition qui concerne la position de chaque ligne de discontinuité par rapport aux caractéristiques.

La seconde note étend ce résultat aux solutions possédant en outre des points singuliers isolés centres d'ondes de détente et de compression (une définition mathématique de ce phénomène aérodynamique est donnée) pourvu que le système soit d'ordre deux et vérifie une condition supplémentaire. *M. Zerner* (Marseille)

Kolesov, Ju. S. 3761
Some existence criteria for stable periodic solutions of quasi-linear parabolic equations. (Russian)
Dokl. Akad. Nauk SSSR **157** (1964), 1288–1290.

Consider the equation $\partial u/\partial t=Lu+f(t,x,u)$, $x\in\Omega$ (bounded), where L is a second-order time-independent elliptic operator and f is periodic in t. Various existence, uniqueness, and stability theorems for periodic solutions $u(x,t)$ vanishing on the boundary Γ are given. The hypotheses on f involve inequalities of the type $f\le au+a_1$ and/or $f\ge bu+b_1$, with a and b compared to the least eigenvalue of $-L$ (with $x=0$ on Γ), and convexity or concavity conditions on f as a function of u. Proofs are omitted. *P. C. Fife* (Minneapolis, Minn.)

Sobolevskiĭ, P. E. 3762
Coerciveness inequalities for abstract parabolic equations. (Russian)
Dokl. Akad. Nauk SSSR **157** (1964), 52–55.

Inégalités de coercivité pour les équations paraboliques abstraites. L'auteur étudie le problème

$$(1)\qquad \frac{dv}{dt}+Av=f,\qquad v(0)=v_0$$

dans l'intervalle $(0,T)$ en supposant que $-A$ est le générateur infinitésimal d'un semi-groupe fortement continu d'opérateurs dans l'espace de Banach E. Pour $\alpha\in]0,1[$, $C_0{}^\alpha(T)$ désigne l'espace des fonctions $t\to w(t)$ continues dans $[0,T]$ à valeurs dans E et telles que

$$\|w\|_{C_0{}^\alpha(T)}=\max_{0\le t\le T}\|w(t)\|_E+\sup_{0<t<t+\Delta t\le T}t^\alpha(\Delta t)^{-\alpha}\|w(t+\Delta t)-w(t)\|_E<+\infty.$$

Le problème (1) est dit coercif dans $C_0^{\alpha}(T)$ si pour tout $f \in C_0^{\alpha}(T)$ et pour tout $v_0 \in D(A)$ il existe une solution v du problème (1), telle que

$$\left\|\frac{dv}{dt}\right\|_{C_0^{\alpha}(T)} + \|Av\|_{C_0^{\alpha}(T)} \leq C(\alpha, T)(\|f\|_{C_0^{\alpha}(T)} + \|Av_0\|_E).$$

L'auteur prouve que le problème (1) est coercif dans $C_0^{\alpha}(T)$ si et seulement si $-A$ est fortement positif, i.e., si $(A+\lambda I)$ est inversible et $\|(A+\lambda I)^{-1}\|_{E\to E} \leq C(|\lambda|+1)^{-1}$ pour $\operatorname{Re}\lambda \geq \sigma_0$. Des notions analogues de coercivité dans des espaces différents de $C_0^{\alpha}(T)$ sont étudiées. L'auteur énonce également des résultats concernant le problème $dv/dt + A(t)v = f$, $v(0) = v_0$ lorsque $D(A(t))$ ne dépend pas de t.

Krasnosel'skiĭ, M. A.; Sobolevskiĭ, P. E. 3763

The structure of the set of solutions of an equation of parabolic type. (Russian. English summary)

Ukrain. Mat. Ž. **16** (1964), 319–333.

The authors present proofs of results announced earlier [Dokl. Akad. Nauk SSSR **146** (1962), 26–29; MR **27** #2730].

The main result of the paper can be formulated as follows: If the mixed boundary-value problem for a nonlinear parabolic equation has two solutions, it has a continuum of solutions.

W. Bogdanowicz (Washington, D.C.)

Browder, Felix E. 3764

Strongly non-linear parabolic boundary value problems.

Amer. J. Math. **86** (1964), 339–357.

The main results of this paper were communicated in the research note [Bull. Amer. Math. Soc. **69** (1963), 858–861; MR **27** #6049]. The equation under consideration is

$$\frac{\partial u}{\partial t} + \sum_{|\alpha|\leq m} D^{\alpha}A_{\alpha}(x, t, u, \cdots, D^m u) = f(x, t).$$

Extending his earlier results on existence of weak solutions by Hilbert-space "monotonicity" methods (in the case where the A_α have at most linear growth as the arguments tend to infinity), the author now attacks the case of "at most polynomial" growth by corresponding L^p-space methods.

Notation: Ω is an open set in R^n, and D_j is $i^{-1}\partial/\partial x_j$; also, u, v are functions over Ω with range in C^r (i.e., complex vector-valued functions). The symbol $\langle u, v\rangle$ stands for $\int_\Omega \sum_{j=1}^r u_j \bar{v}_j$. Also

$$A(t)u = \sum_{|\alpha|\leq m} D^{\alpha}A_{\alpha}(x, t, u, \cdots, D^m u).$$

In the Sobolev space $W^{m,p}(\Omega)$, V stands for a closed linear subspace with $C_0^{\infty}(\Omega) \subset V$, where C_0^{∞} are the C^{∞} functions over Ω satisfying the "boundary condition" of compact support in Ω. The (non-linear) Dirichlet form h is defined by

$$h(u, v) = \sum_{|\alpha|\leq m} \int_{t_0}^{t_1} \langle A_{\alpha}(x, t, u, \cdots, D^m u(t)), D^{\alpha}v(t)\rangle\, dt.$$

The closed line-segment $[t_0, t_1]$ in R^1 is called S, and for given p, the relation $p^{-1} + q^{-1} = 1$ defines q.

It is assumed that A satisfies, besides measurability and continuity hypotheses, the following growth condition on the coefficients: for some $p > 1$, there exist $C > 0$ and function $g \in L^q$ such that for all (x, t) in $\Omega \times R^1$ and eac complex vector $\zeta = \{\zeta_\beta : |\beta| \leq m\}$,

$$|A_{\alpha}(x, t, \zeta)| \leq C \sum_{|\beta|\leq m} |\zeta_\beta|^{p-1} + g(x, t).$$

The main theorem then states that if $A(t)$ also satisfi the "monotonicity" requirement (a) for all u, v in $L^p(S, V$ $\operatorname{Re}\{h(u, u-v) - h(v, u-v)\} \geq 0$, and the "coercivenes requirement (b) there exists a function $c(r) > 0$ wit $c(r) \to +\infty$ as $r \to +\infty$ such that $\operatorname{Re} h(u, v) \geq c(\|u\|)\|u\|$ f all u in $L^p(S, V)$, then the system $\partial u/\partial t + A(t)u = f$ h one and only one weak solution for given $f \in (L^p(S, V))$ The solution is continuous from S to $L^2(\Omega)$ and $u(t_0) =$

The proof of this theorem rests on a rather complicate "monotonicity/complete continuity" theorem in an a stract reflexive separable Banach space; this theorem wi not be quoted here, and is closely related to a theorem Leray and Lions, quoted (without reference) in C. Morrey's multiprinted lecture notes "Multiple integrals i the calculus of variations" for the Amer. Math. So Colloq. Lectures given August 1964 at Amherst, Mas The reader interested in the regularity of the wea solution should refer to Morrey's notes.

Uniqueness of the solution of a conjugate problem i heat transfer. (Russian)

Dokl. Akad. Nauk BSSR **8** (1964), 365–368.

The following problem is considered. The functions $\theta(x,$ and $t(x, y)$ are unknown with $u\theta_x = \chi\theta_{yy}$, $0 \leq x <$ $0 \leq y < \infty$, u and χ constant, $t_{xx} + t_{yy} = -(1/k_s)Q(x, y$ $0 \leq x < \infty$, $-\infty < y \leq 0$, where also k_s is constant. Fo $y = 0$, $x \geq 0$, one sets $\theta|_{y=0^+} - t|_{y=0^-} = f(x)$, an $-k_f\theta_y|_{y=0^+} = -k_s t_y|_{y=0^-} + q(x)$ with $\theta|_{x=0} = 0$, $\theta|_{y=\infty} =$ and $t|_{x=0} = 0$. Some uniqueness theorems are indicated.

Theory of the heat potential. I. Level curves of hea potentials and the inverse problem in the theory of th heat potential. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 660–670.

Let $G(x, t; \xi, \tau)$ denote the fundamental solution o $u_{xx} - u_t = 0$. $W(x, t) = \int_0^t \mu(t)[\partial G(x, t; \varphi(\tau), \tau)/\partial\xi]\, d\tau$ is th double-layer potential corresponding to a density $\mu(t)$ o a curve $x = \varphi(t)$. The author proves that if $\varphi(t)$, $\mu(t)$ ar sufficiently smooth, then the same is true of $W(\varphi(t), t)$ Also, if $\varphi(t)$ and $W(x, t)$ are sufficiently smooth (uniforml for $x > \varphi(t)$), then the same is true of $\mu(t)$. Similar result are established for single-layer potentials.

A. Friedman (Evanston, Ill.

Arima, Reiko; Hasegawa, Yôjiro 376

On the existence of a global true solution in the mixe problem concerning a certain type of semi-linear partia differential equation. (Japanese)

Sûgaku **15** (1963/64), 161–165.

Let $x = (x_1, x_2, x_3) \in R^3$ and $t \in R^1$. In this paper, th following mixed problem for a scalar function $u(x, t)$ i

considered in the domain: $0 \leq x_1 < +\infty$, $-\infty < x_2, x_3 < +\infty$, $0 \leq t < +\infty$:

$$u_{tt} - (\Delta u)_t = f(u)u_t + g(u)$$

with initial conditions $u(x, 0) = u_0(x)$, $u_t(x, 0) = u_1(x)$ and boundary conditions: $u(0, x_2, x_3, t) = \psi(x_2, x_3, t)$. The authors prove the following result. Under the conditions given below, the mixed problem given above has a true solution $u(x, t)$ on the domain: $0 \leq x_1 < +\infty$, $-\infty < x_2, x_3 < +\infty$, $0 \leq t < +\infty$, and $u(x, t)$ satisfies for $0 \leq t < +\infty$ the conditions:

$$t \to u(x, t), \quad u_t(x, t) \in \mathscr{B}_+{}^1(x) \cap \mathscr{D}^2_{L^2+}(x),$$
$$t \to u_{x_ix_i}(x, t), \quad u_{tx_ix_i}(x, t) \in \mathscr{B}_+{}^0(x),$$

where $\mathscr{B}_+{}^k(x)$ is the set of all functions whose derivatives with respect to x of orders $\leq k$ are uniformly continuous and bounded for $x_1 \geq 0$, $-\infty < x_2, x_3 < +\infty$, $\mathscr{D}^k_{L^2+}(x)$ is the set of all functions whose derivatives with respect to x of orders $\leq k$ are in $L^2(x)$ in the same domain, and $t \mapsto u(t, x) \in \mathscr{B}_+{}^k(x) \cap \mathscr{D}^k_{L^2+}(x)$ means that the mapping $t \mapsto u(t, x)$ is continuous with respect to the topologies of $\mathscr{B}_+{}^k(x)$ and $\mathscr{D}^k_{L^2+}(x)$. The conditions on f and g are that (i) $f, g \in C^1$ and $g(0) = 0$; (ii) $f(u) \leq L$, $|f(u)| \leq k_1(u^2+1)$,

$$\text{(iii) } |g(u)| \leq k_2(u^2 + |u|), \qquad G(u) = \int_0^u g(z)\,dz \leq k_3 u^2,$$

where L, k_i are positive constants; the conditions on the initial values are that (i) $u_0, u_1 \in \mathscr{B}_+{}^1(x) \cap \mathscr{D}^2_{L^2+}(x)$, (ii) $u_{0x_ix_i}, u_{1x_ix_i} \in \mathscr{B}_+{}^0(x)$; and the conditions on the boundary values are that

(i) $\quad t \to \psi_t(x_2, x_3, t) \in \mathscr{B}^2(x_2, x_3) \cap \mathscr{D}_{L^2}{}^2(x_2, x_3)$,

(ii) $\quad t \to \psi_{tt}(x_2, x_3, t) \in \mathscr{B}^0(x_2, x_3) \cap \mathscr{D}_{L^2}{}^0(x_2, x_3)$.

The compatibility conditions are that (i) $u_0(0, x_2, x_3) = \psi(x_2, x_3, 0)$, (ii) $u_1(0, x_2, x_3) = \psi_t(x_2, x_3, 0)$, (iii) $\psi_{tt}(x_2, x_3, 0) - \Delta u_1(0, x_2, x_3) = f(\psi(x_2, x_3, 0))\psi_t(x_2, x_3, 0) + g(\psi(x_2, x_3, 0))$. Another similar result is also proved for the case $x \in R^1$ (the one-dimensional case).

The authors first prove the existence of a local solution by the use of successive approximations which can be constructed by using the elementary solution of the heat equation. Then estimates of the local solution and its derivatives with respect to t are derived. By virtue of these estimates, the existence of the global solution is proved.

A particular example of the mixed problems of this kind is given by

$$u_{tt} - u_{txx} = -\mu(1 + u + \varepsilon u^2)u_t - u,$$
$$u(x, 0) = 0, \qquad u_t(x, 0) = 0, \qquad u(0, t) = \psi(t) \in C^\infty,$$

where $x \in R^1$, $\mu > 0$, and $3/16 > \varepsilon > 0$. This particular problem is used to simulate the propagation of the stimulus in the nervous system. The authors' results guarantee the existence of a global solution of this problem.

Y. Sibuya (Minneapolis, Minn.)

Smirnov, M. M. 3768

Some boundary-value problems for an equation of mixed composite type. (Russian)

Sibirsk. Mat. Ž. 5 (1964), 923–928.

Two problems are posed for the equation

$$\frac{\partial}{\partial x}\left(\frac{\partial^2 u}{\partial x^2} + y\frac{\partial^2 u}{\partial y^2} + \alpha\frac{\partial u}{\partial y}\right) = 0$$

($\alpha > 1$) in a domain bounded by the closed segment from $A(-1, 0)$ to $B(1, 0)$ and a curve Γ joining A to B which lies in the upper half-plane and has its maximum ordinate at $N(0, h)$. In the first, values of u are assigned as functions of x on AB, Γ, and of y on ON; in the second, $\lim_{y=0} y^\alpha \partial u/\partial y$ is given as a function of x in $(-1, 1)$, with u as before prescribed on Γ and ON. For each case uniqueness is proved with the use of a maximum principle and existence (for the normal contour Γ_0: $x^2 + 4y = 1$, $y \geq 0$) by reduction to Fredholm integral equations.

R. N. Goss (San Diego, Calif.)

Mel'nik, Z. O. 3769

On a general mixed problem. (Russian)

Dokl. Akad. Nauk SSSR 157 (1964), 1039–1042.

The author claims an existence and uniqueness theorem for a mixed initial-boundary-value problem for a linear hyperbolic integro-differential equation of the form ($a_{m0} = 1$)

$$\sum_{i+j\leq m} a_{ij}(x, t)\frac{\partial^{i+j}u(x, t)}{\partial t^i \partial x^j}$$
$$+ \int_0^t \sum_{i+j\leq m-1} b_{ij}(x, t, \tau)\frac{\partial^{i+j}u(x, \tau)}{\partial t^i \partial x^j}\,d\tau = f(x, t).$$

Initial-values are given on $\{(x, 0); 0 \leq x \leq 1\}$ and boundary conditions on $\{(0, t); 0 \leq t \leq T\}$ and $\{(1, t); 0 \leq t \leq T\}$. The number of boundary conditions on $x = 0$ and $x = 1$ are determined by the number of $\lambda_j(x, t)$ in

$$\sum_{i+j=m} a_{ij}(x, t)\lambda^i \xi^j = \prod_{j=1}^m (\lambda - \lambda_j(x, t)\xi)$$

which are negative and positive, respectively. The boundary conditions themselves are linear integro-differential equations of order $m - 1$ which are assumed to satisfy linear independence conditions of conventional type. The proof (not given in detail in the note) is by reduction to a first-order system and thereafter by the method of characteristics.

V. Thomée (Göteborg)

Finn, Robert 3770

Estimates at infinity for stationary solutions of the Navier-Stokes equations.

Bull. Math. Soc. Sci. Math. Phys. R. P. Roumaine (N.S.) 3 (51) (1959), 387–418.

The author studies the behaviour in the neighbourhood of infinity of the solutions of the three-dimensional, stationary non-linear system of Navier-Stokes equations

$$(1) \qquad \Delta \mathbf{w} - w_k\frac{\partial \mathbf{w}}{\partial x_k} - \operatorname{grad} p = 0, \qquad \operatorname{div} \mathbf{w} = 0.$$

The basic results may be formulated in terms of the following two theorems.

Theorem A. Let $\mathbf{w}(\mathbf{x})$, $p(\mathbf{x})$ be a solution of (1) defined in a neighbourhood of infinity, and let there exist a constant vector $\mathbf{w}_0 \neq 0$ such that $|\mathbf{w}(\mathbf{x}) - \mathbf{w}_0| \to 0$ as $|\mathbf{x}| \to \infty$. Furthermore, let $m(r) = \max_{|\mathbf{x}|\geq r} |\mathbf{w}(\mathbf{x}) - \mathbf{w}_0|$,

$$\gamma(r) = \max_{|\mathbf{x}|\geq r} |\nabla \cdot \mathbf{w}|, \qquad \zeta(r) = \max_{|\mathbf{x}|\geq r} |\nabla p|, \qquad r \gg 1.$$

Then $\gamma(r)$ and $\zeta(r)$ are finite and satisfy the inequalities

$$\gamma(r) < C_1m(r-1), \qquad \zeta(r) < C_2m(r-1),$$

$$p(\mathbf{x}) = O(\log r), \qquad r \to \infty.$$

In addition, the author obtains integral representations for the velocity $\mathbf{w}(\mathbf{x})$ and the pressure $p(\mathbf{x})$ in terms of the fundamental tensor of Oseen.

Theorem B. Suppose that there exist a vector $\mathbf{w}_0 \neq 0$ and constants C and $\varepsilon > 0$ such that $|\mathbf{w}(\mathbf{x}) - \mathbf{w}_0| < Cr^{-1/2-\varepsilon}$, $r = |\mathbf{x}| \to \infty$. Then the velocities of the flow tend to the limit $\mathbf{w}_0$ in the following way. There exists a paraboloidal region with axis $\mathbf{w}_0$ inside which $|\mathbf{w}(\mathbf{x}) - \mathbf{w}_0| < C_1r^{-1}$ (this bound cannot be improved), and outside a certain semi-infinite cone with axis $\mathbf{w}_0$ containing the above paraboloid the stronger inequality $|\mathbf{w}(\mathbf{x}) - \mathbf{w}_0| < C_2r^{-2}$ holds. In addition, the author obtains asymptotic representations for the velocity $\mathbf{w}(\mathbf{x})$ and the pressure $p(\mathbf{x})$, whence it is found that the principal terms in the asymptotic development are determined by the fundamental tensor of Oseen.

The results obtained in Theorem B are used to determine the forces exerted on the surface Σ by the flow, whose velocity tends to the limit $\mathbf{w}_0$ as $|\mathbf{x}| \to \infty$, where these forces are also determined completely by the solutions of the linearized Oseen equations

$$\Delta\mathbf{u} - (\mathbf{w}_0)_k \frac{\partial \mathbf{u}}{\partial x_k} - \operatorname{grad} p = 0, \qquad \operatorname{div} \mathbf{u} = 0, \; \mathbf{u} = \mathbf{w} - \mathbf{w}_0.$$

A. Oskolkov (RŽMat **1963** #11 B308)

Finn, Robert 3771

Estimates at infinity for steady state solutions of the Navier-Stokes equations.

Proc. Sympos. Pure Math., Vol. IV, *pp.* 143–148. *American Mathematical Society, Providence, R.I.*, 1961.

This is a summary of the results in a paper of the author [#3770 above], which, though dated earlier, apparently appeared later than the present summary. As descriptions of the proofs are also given, it is recommended for the reader who wishes to obtain a knowledge of the wealth of material in that paper without perusing the details.

P. C. Fife (Minneapolis, Minn.)

Finn, Robert 3772

An energy theorem for viscous fluid motions.

Arch. Rational Mech. Anal. **6** (1960), 371–381.

This paper treats bounded solutions $\mathbf{w}$ of the steady-state Navier-Stokes system $\Delta\mathbf{w} - \mathbf{w}\cdot\nabla\mathbf{w} - \nabla p = 0$, $\nabla\cdot\mathbf{w} = 0$ in a neighborhood $\mathscr{E}$ of infinity in 3-dimensional space. The primary concern is whether the kinetic energy of disturbance $K(\mathbf{w}_0) = \int_{\mathscr{E}} |\mathbf{w} - \mathbf{w}_0|^2\,dv$ is finite for some constant $\mathbf{w}_0$. If it is, then the Dirichlet integral is finite; and if, furthermore, $\mathbf{w}_0 \neq 0$, then $|\mathbf{w} - \mathbf{w}_0| < C|\mathbf{x}|^{-3/2+\varepsilon}$ for every $\varepsilon > 0$. The main result of the paper is simply stated: if $\mathbf{w}$ vanishes on the boundary of $\mathscr{E}$ but is not identically zero, then $K(\mathbf{w}_0) = \infty$ for every choice of $\mathbf{w}_0$. A further result is a Liouville theorem stating that an entire bounded solution with finite $K(\mathbf{w}_0)$ is a constant.

Finn, Robert 3773

On the steady-state solutions of the Navier-Stokes equations. III.

Acta Math. **105** (1961), 197–244.

L'autore presenta un esteso studio del sistema stazionario di Navier-Stokes:

$$(*) \qquad \mu\Delta\mathbf{w} - \rho(\mathbf{w}\cdot\nabla)\mathbf{w} - \nabla p = 0, \qquad \operatorname{div} \mathbf{w} = 0.$$

Nella prima parte l'autore dà valutazione per l'integrale di Dirichlet (problema interno ed esterno) e dimostra teoremi di esistenza. I risultati trovati sono vicini a quelli dati da O. A. Ladyženskaja [Uspehi Mat. Nauk **14** (1959), no. 3 (87), 75–97; MR **22** #10437], per quanto riguarda il problema interno; nel caso del problema esterno (cfr. il lavoro di Fujita [J. Fac. Sci. Univ. Tokyo Sect. I **9** (1961), 59–102; MR **24** #A2152] e #3770) viene portato questo miglioramento: l'esistenza sussiste se il dato sulla frontiera ha flusso non nullo, purchè sufficientemente piccolo. L'autore, non fa uso di soluzioni generalizzate e dimostra direttamente l'esistenza di soluzioni di tipo classico, il cui gradiente soddisfa ad una condizione di Hölder uniforme. Fra l'altro, viene esposta diffusamente la costruzione di una funzione $w = \operatorname{rot}\psi$ che assume prescritti valori sulla frontiera del dominio.

L'autore esamina poi il comportamento all'infinito delle soluzioni, portando qualche perfezionamento ai suoi precedenti risultati [Arch. Rational Mech. Anal. **3** (1959), 381–396; MR **21** #6167]. Segue un esame critico dei risultati e l'enunciazione di problemi che rimangono aperti. (Tra questi, come è noto, è il problema della unicità della soluzione: per quanto l'unicità di soluzioni "grandi" sia scarsamente attendibile, nessun esempio contrario è attualmente conosciuto.) L'autore nota anche che tutte le dimostrazioni finora date del teorema di esistenza per il problema esterno sono, in certo senso, innaturali perchè ottenute mediante passaggio al limite, a partire da soluzioni di problemi interni.

L'ultima parte del lavoro riguarda l'esame del divario che sussiste tra le soluzioni del sistema di Navier-Stokes e quelle del sistema linearizzato

$$(**) \qquad \mu\Delta\mathbf{u} - \nabla q = 0, \qquad \operatorname{div} \mathbf{u} = 0$$

assumenti gli stessi valori al contorno. Indicando con $\mathbf{w}(\mathbf{x}, \lambda)$ la soluzione (unica se λ è piccolo) del sistema (*) assumente il valore $\lambda\mathbf{w}^*$ sul contorno, con $\mathbf{u}_0$ la soluzione del sistema (**) assumente il valore $\mathbf{w}^*$ sul contorno, si trova, sotto certe condizioni di regolarità per i dati:

$$\left|\frac{1}{\lambda}\mathbf{w}(\mathbf{x}, \lambda) - \mathbf{u}_0(x)\right| < c\lambda \qquad \text{(essendo } c \text{ una costante).}$$

Una analoga limitazione, ma meno forte, vale per il problema esterno.

Fujita, Hiroshi; Kato, Tosio 3774

On the Navier-Stokes initial value problem. I.

Arch. Rational Mech. Anal. **16** (1964), 269–315.

Many theories of the initial-value problem for the Navier-Stokes system have been developed. The present paper is an especially careful and readable account of the authors' version, which is similar in approach and in results to that of Sobolevskiĭ [Dokl. Akad. Nauk SSSR **128** (1959), 45–48; MR **22** #1763; ibid. **131** (1960), 758–760; MR **25** #3282; ibid. **155** (1964), 50–53; MR **28** #4258; ibid. **156** (1964), 745–748; MR **29** #1462]. The essence of the

authors' theory, applied only to a slightly more abstract form of the Navier-Stokes system, was given in Rend. Sem. Mat. Univ. Padova 32 (1962), 243–260 [MR 26 #495]; for the basic existence and uniqueness results, see that review. The present paper simplifies the proofs, presents them in greater detail, extends the results to the system in its classical form, and provides detailed results concerning regularity in the interior, up to the boundary, and as $t \to 0$. For example, if the forcing term is a C^∞ function of t with range in $L_q(D)$ (D is the space domain and $q > 3$), then the solution u and ∇u are in C^∞ with respect to the variable t. A future paper is promised which will include an extension to the case of unbounded D (with bounded complement), and also an extension from this L_2 to an L_p theory. *P. C. Fife* (Minneapolis, Minn.)

Guberman, I. Ja. 3775

On the existence of several solutions of the Dirichlet problem for an equation with a Monge-Ampère operator. (Russian)

Leningrad. Gos. Ped. Inst. Učen. Zap. **238** (1962), 132–140.

The Monge-Ampère equation $rt - s^2 = (1 + p^2 + q^2)^\alpha \times f(x, y, z, p, q)$ with boundary condition $z = 0$ on Γ, where $0 \leq \alpha \leq 1$, Γ a convex curve, and where f is a non-negative and bounded function (with respect to z), was considered by Bakel'man and Krasnosel'skiĭ [Dokl. Akad. Nauk SSSR **137** (1961), 1007–1010; MR **25** #4265]. The author studies the case $\alpha > 1$ and shows by methods similar to those in the cited paper the existence of at least countably many solutions by imposing certain conditions on the growth of the function $f(z)$. Related references are given in Bakel'man [ibid. **114** (1957), 1143–1145; MR **20** #1983; Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **13** (1958), no. 1, 25–38; MR **20** #3384].

V. Linis (Ottawa, Ont.)

Bakel'man, I. Ja. 3776

A variational problem associated with the Monge-Ampère equation. (Russian)

Leningrad. Gos. Ped. Inst. Učen. Zap. **238** (1962), 119–131.

The author studies the variational problem for the functional

$$K(u) = \iint_\Omega [u_x^2 u_{yy} - 2u_x u_y u_{xy} + u_y^2 u_{xx} + 6\phi(x, y)]\, dx dy$$

for which the corresponding formal Euler's equation reduces to the Monge-Ampère equation $u_{xx}u_{yy} - u_{xy}^2 = \phi(x, y)$. In the case $\phi(x, y) > 0$ in Ω (a region with sufficiently smooth boundary of positive curvature bounded from below), the Monge-Ampère equation is of elliptic type; the solutions are convex and unique (in a half-space). The author remarks that $K(u)$ is unbounded in the class of functions $C^2(\Omega)$ and that the Euler's equation is degenerate, its order being two instead of four. The method for obtaining the solution consists of considering $K(u)$ in the region $\Omega - \Omega_\varepsilon$ obtained from Ω by deleting an ε-wide strip along the boundary, and then letting $\varepsilon \to 0$. For the class of totally additive non-negative functions defined on Borel sets in Ω and vanishing on Ω, there exists two solutions of the variational problem; both are convex and one each in opposite half-spaces [cf. the author, Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **13** (1958), no. 1, 25–38; MR **20** #3384; Uspehi Mat. Nauk **15** (1960), no. 1 (91), 163–170; MR **22** #A1918].

FINITE DIFFERENCES AND FUNCTIONAL EQUATIONS

See also 3615, 3835, 4631.

Kuczma, M. 3777

Sur une équation aux différences finies et une caractérisation fonctionnelle des polynômes.

Fund. Math. **55** (1964), 77–86.

Let $\Delta_h^n f(x)$ denote the usual nth difference of a function f, with difference interval h, and let $[x_1, x_2, \cdots, x_{n+1}; f]$ denote the divided difference of order n. Let $J_+^n(a, b)$ denote the class of functions such that $\Delta_h^{n+1} f(x) \geq 0$ for $h > 0$ and $x \in (a, b)$, $x + (n+1)h \in (a, b)$. Similarly, define $J_-^n(a, b)$ by $\Delta_h^{n+1} f(x) \leq 0$, and define $J^n(a, b)$, called the class of convex functions of order n in the sense of Jensen, by the relation $J^n = J_+^n \cup J_-^n$. Let $M_+^n(a, b)$ denote the class of functions such that $[x_1, \cdots, x_{n+2}; f] \geq 0$ for all distinct $x_1, \cdots, x_{n+2}$ in (a, b), and let $M_-^n(a, b)$ denote the class such that $[x_1, \cdots, x_{n+2}; f] \leq 0$. The class $M^n(a, b) = M_+^n(a, b) \cup M_-^n(a, b)$ was introduced by Popoviciu [Mathematica (Cluj) 8 (1934), 1–85], and is here called the class of convex functions of order n.

The author now proves that if $\varphi \in M^n(a, \infty)$, $n \geq 0$, and if φ satisfies $\lim_{x\to\infty} \Delta_1^n \varphi(x) = 0$, then for each pair of real numbers x_0, y_0 there is exactly one solution g of (1) $g(x+1) - g(x) = \varphi(x)$ such that g satisfies the condition $g(x_0) = y_0$ and g is in class $M^n(a, \infty)$. A formula for g is given. This theorem generalizes previous results of the author and of W. Krull [Math. Nachr. **1** (1948), 365–376; MR **11**, 112]. From this theorem is derived a functional characterization of the class P^n of polynomials of degree at most n, namely, that P^n is identical with the class of functions in M^n for which $\Delta_1^{n+1} f(x) = 0$ for $x \in (a, \infty)$.

On the correctness of difference problems. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 308–312.

A connection is established between the correctness of posing a problem and the Fillipov stability of non-linear and linear difference equations.

H. P. Thielman (Alexandria, Va.)

Howroyd, T. D. 3779

The solutions of some functional equations.

Canad. Math. Bull. 7 (1964), 279–282.

From the author's introduction: "In this paper we are concerned with functional equations of the type

$$(1) \qquad f(x+y) = F[f(x), f(y), f(x-y)]$$

in which x, y do not appear explicitly. J. Aczel [*Vorlesungen über Funktionalgleichungen und ihre Anwendungen*, Chapter 2, Birkhäuser, Basel, 1961; MR **23** #A1959] has given a method for finding real solutions of some of

these equations. We prove a theorem which can sometimes be used to solve problems concerning the uniqueness of solutions of such equations."

Mitrinović, Dragoslav S. 3780

Sur les équations fonctionnelles linéaires paracycliques de seconde espèce. (Serbo-Croatian summary)

Glasnik Mat.-Fiz. Astronom. Društvo Mat. Fiz. Hrvatske Ser. II 18 (1963), 177–182.

The author considers the functional equation

$$(*)\quad f_1(x,y,u)+f_2(y,x,v)+f_3(x,u,v)+f_4(y,v,u) = 0,$$

where $f_1, \cdots, f_4$ are 3-place functions from an arbitrary set E to an Abelian group M which has the property that the equation $mX=A$ has a unique solution X for any A in M and any integer m. He shows that the general solution of (*) has the form

$$\begin{aligned} f_1 &= F_1(I,K)+G_1(J,K)+H_1(I,J),\\ f_2 &= F_2(J,K)+G_2(I,K)-H_1(J,I),\\ f_3 &= -F_1(I,J)-F_2(I,K)+H_2(J,K),\\ f_4 &= -G_1(I,K)-G_2(I,J)-H_2(K,J), \end{aligned}$$

where $F_1, \cdots, H_2$ are arbitrary 2-place functions from E to M and I, J, K are the 3-place selectors on E, i.e., for any u, v, w in E, $I(u,v,w)=u$, $J(u,v,w)=v$, $K(u,v,w)=w$. He also shows that if $f_1=f_2=f_3=f_4=f$, then $f=g(I,J)-g(J,I)+g(J,K)-g(K,J)+g(K,I)-g(I,K)+h(I)-2h(J)+h(K)$, where g and h are arbitrary functions from E to M. *B. Schweizer* (Tucson, Ariz.)

Vincze, E. 3781

Eine allgemeinere Methode in der Theorie der Funktionalgleichungen. III, IV.

Publ. Math. Debrecen 10 (1963), 191–202; *ibid.* 10 (1963), 283–318.

Part II appeared in same Publ. 9 (1962), 314–323 [MR 27 #2749]. The following functional equations are solved.

$$(1)\quad F(z_1+z_2) = G(z_1)H(z_2)+K(z_1)L(z_2);$$

$$(2)\quad F(z_1+z_2) = F(z_1)+F(z_2)+G(z_1)H(z_2)+G(z_2)H(z_1);$$

$$(3)\quad F(z_1+z_2) = F(z_1)+F(z_2)+G(z_1)G(z_2)+H(z_1)H(z_2).$$

Here, all functions have as their domain an abelian group and have complex values. The solutions are expressed in terms of the solutions of

$$\begin{aligned} \phi(z_1+z_2) &= \phi(z_1)+\phi(z_2),\\ \psi(z_1+z_2) &= \psi(z_1)+\psi(z_2). \end{aligned}$$

Equations (1), (2), (3) have, respectively, 6, 5, and 6 essentially different types of solutions. *A. Nijenhuis* (Philadelphia, Pa.)

Aczél, J.; Vincze, E. 3782

Über eine gemeinsame Verallgemeinerung zweier Funktionalgleichungen von Jensen.

Publ. Math. Debrecen 10 (1963), 326–344.

En partant d'une méthode simple qu'ils utilisent pour la résolution de l'équation:

$$(a)\quad f(x+y)+f(x-y)-2f(x) = 2|y|g(x),$$

les auteurs étudient par la même méthode l'équation plus générale

$$(b)\quad f(x+y)+f(x-y)-2f(x) = 2g(x)h(y).$$

Cette dernière équation est étudiée aussi dans toute sa généralité quand les fonctions f et g sont définies sur un groupe abélien, et ont des valeurs complexes. L'équation (b) contient deux cas particuliers de J. L. W. V. Jensen

$$f\left(\frac{u+v}{2}\right) = \frac{f(u)+f(v)}{2}$$

et

$$f(x+y)+f(x-y)-2f(x) = 2f(y).$$

Sakovič, G. N. 3783

Functional equations for sums of exponentials. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR 1964, 714–718.

Functions of the form $f(x)=\sum P_i(x)e^{a_ix}$, where $P_i(x)$ are polynomials, can be characterized as the solutions of linear differential equations with constant coefficients. The present author points out that these functions can also be characterized as the solutions of some functional equations, of which $f(x+y)=\sum_{i,j=1}^{n} a_{ij}f_i(x)f_j(y)$ is a typical example. {It is not stated under what regularity conditions this is true; some conditions, though very weak, are necessary. E.g., it would be enough to assume that $f(x)$ is measurable.} The proof is outlined.

The author's references might be supplemented by W. Eichhorn [Arch. Math. 14 (1963), 266–270; MR 27 #3956] and F. Radó [Mathematica (Cluj) 4 (27) (1962), 131–143; MR 27 #2667]. The latter paper covers one of the four cases considered by the present author. *M. Kuczma* (Katowice)

Bhatnagar, P. L.; Srinivasienagr, C. N. [Srinivasiengar, C. N.] 3784

★**The theory of infinite series.**

National Publishing House, Delhi, 1964. vii+196 pp. Rs. 10.00.

This monograph is at about the same level as, but on the whole more detailed, in those topics that both books cover, than Hirschman's *Infinite series* [Holt, Rinehart and Winston, New York, 1962; MR 26 #510]. It includes a number of rather refined theorems that do not usually appear in a short monograph. The style is rather old-fashioned; more advantage could have been taken of modern terminology and points of view. Contents: Infinite sequences; infinite series; series of positive terms; series in general; derangement of series; double series; multiplication of series; uniform convergence; real power series; infinite products; Tannery's theorems; complex series and products; transformation of a convergent series into a more rapidly convergent series; summability processes. The phrase "Tannery's theorems" will be unfamiliar to most readers nowadays. These theorems

deal with limits of uniformly convergent sums and products of a special form.

R. P. Boas, Jr. (Evanston, Ill.)

Diananda, P. H. 3785

On rearrangement of series. IV.

Colloq. Math. **12** (1964), 85–86.

Part III appeared in same Colloq. **10** (1963), 287–288 [MR **27** #5060]. This paper is an addendum to Part II of the author's paper of the same title [ibid. **9** (1962), 277–279; MR **27** #5059]. He denotes there by (1), (2), (3), (5) and (6) the following relations: (1) $na_n \to 0$ as $n \to \infty$; (2) $(a_{N_1} + \cdots + a_{N_n}) - (a_1 + \cdots + a_n) \to 0$ as $n \to \infty$; (3) $\sum_{r > n \geq N_r} 1/N_r = O(1)$ as $n \to \infty$; (5) $\sum_{r \leq n < N_r} 1/N_r \to 0$ as $n \to \infty$; (6) $\sum_{r > n \geq N_r} 1/N_r \to 0$ as $n \to \infty$. In this addendum he states the following theorem: A necessary and sufficient condition (NSC) that (5) be true for every (a) series, (b) divergent series, satisfying (6) and (7) $\sum_{r \leq n < N_r} a_{N_r} = o(1)$ as $n \to \infty$ is (3). If (5) is replaced by (1) an NSC is (8) $\sum_{r > n \geq N_r} 1/N_r = o(1)$ as $n \to \infty$. If (6) and (7) are replaced by (2) an NSC is (3). Also (1) is necessarily satisfied. Relation (8) is an NSC that (1) be true for every (a) series, (b) divergent series, satisfying (6).

J. W. Andrushkiw (S. Orange, N.J.)

Banerjee, C. R.; Lahiri, B. K. 3786

On subseries of divergent series.

Amer. Math. Monthly 71 (1964), 767–768.

The following theorem is proven. Let $u(1) + u(2) + u(3) + \cdots$ be a divergent series of positive terms for which $\lim u(n) = 0$. Let P be a positive number. Then there exists a subseries $u(n_1) + u(n_2) + u(n_3) + \cdots$ $(n_1 < n_2 < n_3 < \cdots)$ which converges to P. It is also shown how to construct the convergent subseries.

J. W. Andrushkiw (S. Orange, N.J.)

Seall, Robert; Wetzel, Marion 3787

Quadratic forms and chain sequences.

Proc. Amer. Math. Soc. 15 (1964), 729–734.

Sequences $\{a_n\}$, $\{b_n\}$ form a double chain sequence if, for $n = 1, 2, \cdots$,

$$a_n = 4(1 - g_{2n-2})(1 - g_{2n-1})g_{2n-1}g_{2n},$$
$$b_n = 2(1 - g_{2n-2})(1 - g_{2n-1}) + 2g_{2n-2}g_{2n-1} - 1,$$

where $0 \leq g_{n-1} \leq 1$, $g_{-1} = 1$, $g_0 = 0$. The authors used double chain sequences in an earlier paper [Pacific J. Math. **9** (1959), 861–873; MR **23** #A1966] to characterize the monotone moment problem on $[-1, 1]$ in terms of Jacobi-type continued fractions. In the present paper a direct inductive proof is given that the quadratic forms $\sum_1^n (1 + \varepsilon b_p)x_p^2 - 2\sum_1^{n-1} a_p x_p x_{p+1}$ $(n = 1, 2, \cdots; \varepsilon = \pm 1)$, are positive semidefinite if and only if $\{a_n\}$, $\{b_n\}$ is a double chain sequence. Formulas are given for the minimal parameters of the double chain sequence and extension to double chain sequences of some results for ordinary chain sequences is indicated. *W. T. Scott* (Tempe, Ariz.)

Ishiguro, Kazuo 3788

On the Sonnenschein methods of summability.

Math. Z. **84** (1964), 374–377.

The following two theorems are proved. (1) The generalized Euler summation method is the only method, regular or not, which is common to the $[F, d_n]$ and Sonnenschein summation schemes. (2) Let $J(x) = \sum_0^\infty p_k x^k$, $p_k \geq 0$, be an entire function and $s_0, s_1, \cdots$ a given sequence. Define $J_s(x) = \sum_0^\infty s_k p_k x^k$. If $J_s(n)/J(n) \to s$ as $n \to \infty$ $(n = 1, 2, \cdots)$, then $\{s_k\}$ is said to be summable J^* to s. The method generated by $J(x) = a^x$, $a > 1$ (equivalent to Borel's exponential means if n is replaced by x), is the only method which is of both J^* and Sonnenschein types.

{Reviewer's remarks: (i) Result (2) is rephrased from the paper where it is stated imprecisely; (ii) the references made by the author to L. Lorch alone (p. 374 and p. 377[4]) should be jointly to L. Lorch and D. J. Newman [Comm. Pure Appl. Math. **15** (1962), 109–118; MR **26** #2805].} *L. Lorch* (Edmonton, Alta.)

Ishiguro, Kazuo 3789

On the Lebesgue constants for quasi-Hausdorff methods of summability. I, II.

Proc. Japan Acad. **40** (1964), 188–191; *ibid.* **40** (1964), 192–195.

The quasi-Hausdorff methods considered here are those generated by weight function $\psi(r)$, $0 \leq r \leq 1$, with $\psi(r)$ a step function and $\psi(1) = 1$, $\psi(0) = \psi(+0) = 0$, which suffices to assure regularity. Under these assumptions it is shown that the nth Lebesgue constant for the application of such a method to Fourier series is $C^*(\psi) \log n + o(\log n)$. $C^*(\psi)$ depends only on ψ; its value is given explicitly. This result subsumes in part an earlier one on the circle or (γ, r) method of summation (a particular quasi-Hausdorff method) obtained first by the present author [same Proc. **36** (1960), 470–474; MR **23** #A1205], and subsequently rederived with other methods by the reviewer and D. J. Newman [Canad. Math. Bull. **6** (1963), 179–182; MR **27** #6083]. {Unfortunately, the author omits Newman's name in referring to this article, p. 188, line 8 from the bottom, p. 195, reference [4].} The present result is analogous to a special case of one obtained for all regular Hausdorff methods by the reviewer and D. J. Newman [Canad. J. Math. **13** (1961), 283–298; MR **27** #502] and is established in a similar way. {In this last reference $\psi(r)$ is not restricted to be a step function, although only this case is cited (as Theorem 2) in the present paper.}

L. Lorch (Edmonton, Alta.)

Sen, Mira 3790

Extension of a theorem of Hyslop on absolute Cesàro summability.

Proc. Japan Acad. **40** (1964), 183–187.

Let $\sum u_n^{(\delta)}$ denote the Cesàro (C, δ)-transform of $\sum u_n$, $\delta > -1$. By definition, absolute summability $|C, \delta|$ of $\sum u_n$ means absolute convergence of $\sum u_n^{(\delta)}$. Hyslop proved that, for $0 < k < 1$, absolute convergence of $\sum n^k u_n^{(p)}$ is equivalent to $|C, p|$ summability of $\sum n^k u_n$ (here p is a positive integer).

In this short but important paper a monotonic increasing sequence $\{\lambda_n\}$, $\lambda_n \to \infty$, replaces $\{n^k\}$ of Hyslop's theorem. The last is now split into two theorems. The first one formulates the properties of $\{\lambda_n\}$ which make the convergence of $\sum \lambda_n |u_n^{(p)}|$ a sufficient condition of the summability $|C, p|$ of the series $\sum \lambda_n u_n$. The second theorem

gives the properties of $\{\lambda_n\}$ under which the convergence of $\sum \lambda_n |u_n^{(p)}|$ is a necessary condition of the summability $|C, p|$ of $\sum \lambda_n u_n$. *E. Kogbetliantz* (New York)

Slepenčuk, K. M. 3791

Some special summation methods for infinite products. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1963**, no. 6 (37), 133–137.

Let $\alpha \geq 0$, $1 \leq k_1 \leq k_2 \leq \cdots$, and $\lim_{n\to\infty} k_n = \infty$. Given an infinite product $\prod (1+u_i)$, the sequence $\{P_n\}$ defined by

$$P_n = \prod_{i=1}^{n} \left(1 + \left(1 - \frac{k_i^{\alpha}}{k_n^{\alpha+1}}\right)^{k_i} u_i\right), \qquad n = 1, 2, \cdots,$$

is called the (K, α) transform of $\prod (1+u_i)$. If $\lim_{n\to\infty} P_n = \sigma \neq 0$, the infinite product $\prod (1+u_i)$ is said to be (K, α) summable to σ. The author proves the following regularity theorem: In order that every convergent infinite product should be (K, α) summable to the same value it is necessary and sufficient that the sequence

$$\sum_{i=1}^{n} (k_i/k_n)^{\alpha+1}, \qquad n = 1, 2, \cdots,$$

be bounded. *R. Bojanic* (Columbus, Ohio)

Dawson, David F. 3792

Some rate invariant sequence transformations.

Proc. Amer. Math. Soc. **15** (1964), 710–714.

The author uses the following basis for comparing convergence rates of series: If $\sum a_p$ and $\sum b_p$ are convergent series, then "$\sum a_p$ converges faster than $\sum b_p$" means that

$$\lim_{n\to\infty} \sum_{p=n}^{\infty} a_p \Big/ \sum_{p=n}^{\infty} b_p = 0.$$

An equivalent definition for sequences is given. Also, the relative rate of divergence of two series (or sequences) is defined similarly. The following definition is also used: "A sequence-to-sequence transformation A is rate (of convergence) invariant" means that if each of x and Ax is a convergent sequence, then neither sequence converges faster than the other.

The following theorems are proved: Theorem 1: If $\sum |a_p|$ converges and $d_p \to k$, then the convergence-preserving matrix $A = (a_{pq})$ defined by $a_{pq} = 0$ if $q > p$, $a_{pq} = d_p$ if $p = q$, $a_{pq} = a_q$ if $q < p$, speeds up the convergence of some null sequence if and only if $k = 0$. Theorem 2: If $\sum_{i=N}^{\infty} |1 - p_{i+1}/p_i|$ converges for some N, then for each convergent series $\sum a_i$, the series $\sum a_i$ and $\sum p_i a_i$ are rate invariant.

Another theorem similar to Theorem 1 is also given, as are two partial converses to Theorem 2. Finally, two theorems on rate of divergence are proved.

Golubov, B. I. 3793

On the summability of sequences. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, no. 4 (41), 47–55.

D'après R. C. Buck et H. Pollard [Bull. Amer. Math. Soc. **49** (1943), 924–931; MR **5**, 117] il existe une correspondance biunivoque entre les nombres de $(0, 1)$ et la suite des nombres naturels de la manière suivante. Soient $x \in (0, 1]$ et $x = 0$, $\alpha_1(x)\alpha_2(x)\cdots$ la représentation de x par une fraction duale (avec une infinité des chiffres 1), alors $x \sim \{n_k\}$ où n_k est tel que $\alpha_{n_k}(x) = 1$, $\alpha_n(x) = 0$, $n \neq n_k$ $(k = 1, 2, \cdots)$. La réciproque est aussi vrai: A toute suite de nombres naturels strictement croissants $\{n_k\}$ correspond, par les mêmes lois, un point $x \in (0, 1]$.

Soient $\{s_n\}$ une suite, $s(n, x)$ sa suite partielle définie par $x \in (0, 1]$, s_n' l'ensemble des points limites de s_n, $T = \|a_{n,k}\|$ un procédé régulier de sommation, $\sigma_n(s) = \sum_{k=1}^{\infty} a_{n,k} s(k, x)$, alors l'auteur démontre: Pour toute suite $\{s_n\}$ on peut trouver un ensemble $Q \in (0, 1]$ de mesure positive et de deuxième catégorie sur $(0, 1]$ tel que $\{s(n, x)\}' = \{s_n\}'$, $x \in Q$. Si $|s_n| \leq C$ pour tout procédé régulier T il existe $Q \in (0, 1)$ de deuxième catégorie sur $(0, 1]$ tel que $\{\sigma_n(x)\}' \supset \{s_n\}'$, $x \in Q$. L'auteur donne des résultats analogues concernant les réarrangements des séries à termes constants et à termes variables.

M. Tomić (Belgrade)

Meir, Amram 3794

Tauberian constants for a family of transformations.

Ann. of Math. (2) **78** (1963), 594–599.

Let $\sum u_n$ be a series of complex terms, let $s_n = u_0 + u_1 + \cdots + u_n$, and let the linear transformation $t_p = \sum_{k=0}^{\infty} c_{pk} s_k$ satisfy the conditions (i) there exist a positive constant a and a positive increasing function $q = q(p)$ such that, for every fixed δ $(\frac{1}{2} < \delta < \frac{2}{3})$,

$$c_{pk} = (a/\pi q)^{1/2} \exp\{-a(k-q)^2/q\} \times \left(1 + O\left(\frac{|k-q|+1}{q}\right) + O\left(\frac{|k-q|^3}{q^2}\right)\right)$$

as $p \to \infty$, uniformly in k for $|k-q| \leq q^{\delta}$; (ii) $\sum k c_{pk} = O\{\exp(-q^{\eta})\}$, where η is some positive number independent of p and where the summation is taken over all k satisfying $|k-q| > q^{\delta}$.

The author's main result is that if $n(\beta)$ and $p(\beta)$ increase monotonically and tend to $+\infty$ with β, and if

$$\limsup_{\beta\to\infty} |n-q| \cdot q^{-1/2} = M < \infty,$$

then the least constant A_M such that $\limsup_{\beta\to\infty} |s_n - t_p| \leq LA_M$ for every series $\sum u_n$ which satisfies the Tauberian condition $\limsup |n^{1/2} u_n| = L < \infty$, is given by

$$A_M = (a\pi)^{-1/2}\left(e^{-aM^2} + 2aM \int_0^M e^{-ax^2}\, dx\right).$$

The case of the Borel transform, in which $c_{pk} = e^{-p} p^k / k!$ and $a = \frac{1}{2}$, $q = p$, is due to Agnew [Math. Z. **67** (1957), 51–62; MR **18**, 732]. *P. Heywood* (Edinburgh)

Rice, John R. 3795

★**The approximation of functions. Vol. I: Linear theory.**

Addison-Wesley Publishing Co., Reading, Mass.-London, 1964. xi + 203 pp. \$8.75.

This volume is centered on the approximation of real continuous functions by approximating functions which

depend linearly on a finite number of parameters. The book will be summarized by a selective listing of its contents.

Chapter One: Fundamentals. Various norms which are common in approximation theory are introduced and appraised, and the theorem of Pólya on the convergence of best L_p approximations to a best Tchebycheff approximation as $p \to \infty$ is proved. There follows a useful heuristic discussion on "choice of form and norm". The chapter concludes with the basic theorem on the existence of best approximations.

Chapter Two: Least Squares and Orthogonal Functions. The explicit solution of the problem of least squares approximation to a function on an interval by a linear combination of a finite number of linearly independent functions is given first. There follows a brief discussion of orthogonal polynomials on an interval and on a finite point set. Approximation on an interval as the limit of approximation on a finite point set comes next. The final topic in this chapter is the Gram-Schmidt orthogonalization technique.

Chapter Three: Tchebycheff Approximation. Standard characterization and uniqueness results are given for uniform approximation by a linear combination of functions on an interval and related to results on a finite point set. Tchebycheff-type theory is then extended to approximation by unisolvent functions and rational functions. There follows a discussion of the limits of Tchebycheff-type theory. These latter sections contain much material due to the author.

Chapter Four: Approximation in the L_1 Norm. The characterization of best L_1 approximations is followed by a proof of Jackson's uniqueness theorem. A brief discussion of L_1 approximation on a finite point set concludes this chapter.

Chapter Five: The Weierstrass theorem is given, and Jackson's theorem on degree of convergence is proved.

Chapter Six: Computational Methods. Transformations of known expansions are first discussed, then telescoping procedures. Descent methods are thoroughly studied as well as ascent methods for Tchebycheff approximation. Finally, connections between approximation techniques and linear programming are treated.

Each chapter is followed by a generous section of problems. Some of the problems are substantial pieces of work, and they are starred. As the summary shows, the author has covered a lot of ground in a small volume. He has everywhere been willing to give the germinal ideas behind proofs and methods. For this heuristic quality the reader will be grateful. However, the book also gives the impression of having been composed in great haste. Definitions are sometimes careless and imprecise. For example: the word "parameter" on page 2 is used both for the individual components of a vector and the vector itself. According to Definition 3-3, 0 is a simple zero of x^3. Among other instances of error are Problem 3-2, which is quite wrong (although the student who straightens it out will never forget the property of the Tchebycheff polynomials involved), and Problem 3-20a. The value 100 for the constant in Jackson's theorem on degree of convergence is not obtained in the proof given, despite the assertion that it is on page 139. Some purely typographical errors were also noted. A list of these may be obtained from the author.

Lambert, Pol V. 3796

Two theorems in the approximation of functions of two variables by polynomials of the Bernstein-type.

Simon Stevin **36** (1962/63), 122–130.

Let $f(x, y)$ be a real function defined and bounded on the triangle $S=\{(x, y): x \geq 0, y \geq 0, x+y \leq 1\}$. For $n=1, 2, \cdots$, let

$$B_n(x, y) = \sum_{\substack{k\geq 0,\, m \geq 0,\\ k+m\leq n}} f\left(\frac{k}{n}, \frac{m}{n}\right) n! \times [k!m!(n-k-m)!]^{-1} x^k y^m (1-x-y)^{n-k-m}.$$

Then for every $(x, y) \in S$ one has $|B_n(x, y)-f(x, y)| \leq 1.5\,\omega(n^{-1/2}, n^{-1/2})$, where for every positive δ_1, δ_2,

$$\omega(\delta_1, \delta_2) = \sup_{\substack{|x-x'|<\delta_1,\, |y-y'|<\delta_2\\ (x,y)\in S,\, (x',y')\in S}} |f(x', y')-f(x, y)|.$$

The author also gives an analogue of an asymptotic formula due to E. V. Voronovskaja [Dokl. Akad. Nauk SSSR (A) **1932**, 79–85]. *O. Shisha* (Dayton, Ohio)

Grigor'eva, I. A. 3797

An application of a method of Chebyshev and Bernstein to a class of extremal functions satisfying certain relations which are linear with respect to the coefficients. (Russian. English summary)

Ukrain. Mat. Ž. **16** (1964), 283–291.

The author indicates a way to determine the solution of the problem $\int_{-1}^{+1} p(x) y_n(x)\,dx = \min$, where $y_n(x) = \sum_0^n p_k x^k$ is a polynomial of degree n, positive on an interval $[-a, a]$, whose coefficients satisfy the conditions $\sum_{k=0}^n a_{kj} = A_j$, $j=1, \cdots, s$. She gives applications to extremal problems for multiply monotone polynomials.

G. G. Lorentz (Syracuse, N.Y.)

Pogodičeva, N. A. 3798

Lebesgue functions for certain linear methods of approximation by ordinary polynomials on a finite interval. (Russian)

Ukrain. Mat. Ž. **15** (1963), 100–101.

Let $P_n(f, x)$ be a linear combination of the first n Chebyshev polynomials that interpolates to a continuous function $f(x)$ over $[-1, 1]$. Let $V_n(f, x, \lambda)$ be $P_n(f, x)$ modified by the inclusion of arbitrary but bounded constants as multipliers of the coefficients. The author gives an asymptotic relation for large n for $\sup |V_n(f, x, \lambda)|$ taken over $|f(x)| \leq 1$. *R. G. Langebartel* (Urbana, Ill.)

Szász, Paul 3799

On generalized quasi-step and almost-step parabolas, respectively.

Ann. Univ. Sci. Budapest. Eötvös Sect. Math. **6** (1963), 13–15.

Given a function $f(x)$ continuous in the closed interval $[-1, 1]$, the author constructs a polynomial $S_n(x)$, of degree not exceeding $2n+1$, from the zeros of the Jacobi polynomial $P_n^{(\alpha,\beta)}(x)$ and states conditions under which $S_n(x)$ converges (and converges uniformly) to $f(x)$. Here $0 \leq \alpha < 1$, $0 \leq \beta < 1$. He states an analogous result for the case in which $\alpha = \frac{1}{2}$, $\beta = -\frac{1}{2}$. No proofs are supplied.

L. Lorch (Edmonton, Alta.)

Bajšanski, B.; Bojanić, R. 3800

A note on approximation by Bernstein polynomials.

Bull. Amer. Math. Soc. **70** (1964), 675–677.

Let $f=f(x)$ be a function defined on the interval $I=[0, 1]$, and consider the corresponding Bernstein polynomial of degree n: $B_n(f;x)=\sum_{\nu=0}^{n}\binom{n}{\nu}x^\nu(1-x)^{n-\nu}f(\nu/n)$. If f has a continuous derivative f' on the interval I, then we have the following inequality, established by G. G. Lorentz [*Bernstein polynomials*, Univ. Toronto Press, Toronto, Ont., 1953; MR 15, 217]:

$$|f(x)-B_n(f;x)| \leq 0.75n^{-1/2}\omega_1(n^{-1/2}),$$

where $\omega_1(\delta)$ is the modulus of continuity of f'. In particular for $f'\in \mathrm{Lip}\,1$ it follows that we have $|B_n(f;x)-f(x)|=O(n^{-1})$. It is known that $O(n^{-1})$ cannot be improved by increasing the smoothness of f, because of the well-known theorem of Voronovskaja. In Lorentz's book it has been conjectured that a continuous function f defined on I can satisfy $|B_n(f:x)-f(x)|=o(n^{-1})$ uniformly on some interval only if f is linear on that interval. Let $0\leq\alpha<\beta\leq 1$. In this paper the authors prove the following theorem: If f is continuous on the interval I and if $B_n(f;x)-f(x)=o(n^{-1})$ holds for each fixed $x\in(\alpha,\beta)$, then f is a linear function on $[\alpha,\beta]$. This theorem complements the important results obtained by K. de Leeuw [J. Analyse Math. 7 (1959), 89–104; MR 22 #3916] in connection with this kind of problem.

Generating functions for sequences of Euler-Bernstein polynomials. (Russian. Estonian and English summaries)

Eesti NSV Tead. Akad. Toimetised Füüs.-Mat. Tehn.-tead. Seer. **12** (1964), 115–120.

The author finds generating functions for the extremal cyclic polynomials $C_n(x)$, $S_n(x)$ of Euler and Bernstein [S. Bernštein, *Collected works* (Russian), Vol. II, pp. 493–516, Izdat. Akad. Nauk SSSR, Moscow, 1954; MR **16**, 433], and derives several identities.

G. G. Lorentz (Syracuse, N.Y.)

Moursund, D. G. 3804

Chebyshev approximations of a function and its derivatives.

Math. Comp. **18** (1964), 382–389.

Let X be a compact subset of the real line. Let $n\geq 0$, $r\geq 1$ be fixed integers. Let $f(x)$ (the function to be approximated) and the base functions $\phi_0(x),\cdots,\phi_n(x)$ be of class C^r in an interval $[a,b]$ containing X. Finally, let

$$M[g] = \max_{k=0,\cdots,r}\|w_k(x)D^kg(x)\|,$$

where $\|\cdot\|$ denotes the uniform norm on X. The problem is to find the coefficients $a_0,\cdots,a_n$ such that $M[\sum a_i\phi_i(x)-f(x)]$ is a minimum. Beginning with a numerical example for $\phi_i(x)=x^i$, $r=1$ and X a set of five points, while $n=5$, 6, 7, 8, and 9, the general discussion leads to a characterization theorem for solutions. We quote only the last of the four theorems. Let $X=[-1,1]$, $r=1$, $\phi_i(x)=x^i$, $i=0,\cdots,n$, and assume $w_0(x)$ and $w_1(x)\in C^1$, $f(x)\in C^2$. Then either the best approximation P is unique, or else it is unique up to an appropriate additive constant. In the latter case, $DP(x)=P'(x)$ is the best Chebyshev approximation of degree $n-1$ to $f'(x)$ for the weight function $w_1(x)$.

Mamedov, R. G. 3805

Some general results on the asymptotic value and order of approximation of functions by a family of positive linear operators. III. (Russian. Azerbaijani summary)

Izv. Akad. Nauk Azerbaĭdžan. SSR Ser. Fiz.-Mat. Tehn. Nauk **1963**, no. 1, 3–13.

Part II appeared in same Izv. **1962**, no. 6, 3–13 [MR **27** #2770]. The problem is to determine the rate of convergence of approximations to a continuous function of period 2π, assuming that the approximating functions are obtained by a positivity-preserving linear process. In polynomial and trigonometric approximation, the rate of convergence is known to be determined by the degree of differentiability of the function approximated. The author now subsumes a number of such results in a general theorem which expresses the rate of convergence to a $2m$-times differentiable function in terms of its left and right derivatives of order $2m+1$ at a point. The principal hypotheses are differentiability conditions on the functions produced by the approximation process. The general problem of relating rate of convergence to local conditions (such as differentiability) is also considered.

The author derives asymptotic expansions of

$$\alpha S_{n-1}(\alpha) = \alpha \sum_{\nu=1}^{n-1} \nu^{\alpha-1} \qquad (\alpha \text{ complex})$$

and related expressions, for large n, by a method based on infinite series without the use of integration.

A. E. Ingham (Cambridge, England)

Fedorjuk, M. V. 3808

The stationary-phase method. Near-by saddle points in the higher-dimensional case. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. 4 (1964), 671–682.

Consider the integral

$$\Phi(k, \alpha) = \int_D e^{ikf(x,\alpha)}\varphi(x, \alpha)\,dx,$$

$x = (x_1, \cdots, x_n)$, $D \in E^n$, $k \to \infty$, under the assumption that the function $f(x, \alpha)$ has two nearby stationary points, x_1 and x_2, that coalesce for $\alpha = 0$. The principal result obtained is the following (not all the hypotheses are stated in detail): if $f(x, \alpha)$ and $\varphi(x, \alpha)$ are regular in a neighborhood of x^0 for $|x_j - x_j^0| < \delta'$, $|\alpha| < \delta'$, and infinitely differentiable for $|x_j - x_j^0| < \delta$, $|\alpha| < \delta$, where D is now the region $|x_j - x_j^0| \leq \delta$, $1 \leq j \leq n$, then

$$\Phi(k, \alpha) \sim k^{(n-1)/2} \exp[ikF(\alpha)] \sum_{m=0}^{\infty} \Phi_m(k, \alpha, \zeta)k^{-m},$$

where

$$\Phi^m(k, \alpha, \zeta) = \sum_{j=1}^{4} w_j(\zeta, k) \sum_{s=0}^{m} \frac{a_{js}(\alpha)}{k^{2s}} + O(k^{-2m-2}),$$

$$w_j(\zeta, k) = v(\zeta)/k^{(3j-1)/6} \quad \text{for } j \text{ odd},$$
$$= v'(\zeta)/k^{(3j-2)/6} \quad \text{for } j \text{ even},$$

$$F(\alpha) = \tfrac{1}{2}[f(x_1(\alpha), \alpha) + f(x_2(\alpha), \alpha)],$$

$$\zeta^{3/2} = -\tfrac{3}{4}k[f(x_1(\alpha), \alpha) - f(x_2(\alpha), \alpha)],$$

$v(\zeta)$ is an Airy integral, and a_{js} are regular functions of α for small α. In addition, a formula is given for the first two terms of the above representation in terms of the square root of

$$\det \left\| \frac{\partial^2 f(x^j(\alpha), \alpha)}{\partial x_k \partial x_l} \right\|, \qquad j = 1, 2.$$

La représentation de la différence divisée d'une fonction de deux variables par une intégrale double.

Mathematica (Cluj) 3 (26) (1961), 59–78.

Ionescu, D. V. 3809b

La représentation de la différence divisée d'une fonction de deux variables par une intégrale double. II.

Mathematica (Cluj) 3 (26) (1961), 231–271.

These papers obtain a representation for the divided difference of order (m, n) of a function $f(x, y)$ of two variables as a double integral

$$\begin{bmatrix} x_0, x_1, \cdots, x_m \\ y_0, y_1, \cdots, y_n \end{bmatrix}; f \bigg] = \iint_D \phi(x, y) \frac{\partial^{m+n} f}{\partial x^m \partial y^n}\,dx\,dy,$$

where D is the rectangle $x_0 \leq x \leq x_m$, $y_0 \leq y \leq y_n$. It is assumed that the nodes in the divided difference are simple. The function $\phi(x, y)$ is uniquely determined and the main purpose of these papers is to study its properties in detail. Much information is obtained about $\phi(x, y)$ which we cannot summarize here. One important result is that $\phi(x, y)$ has a constant sign of $(-1)^{m-n}$ on D. This result is important in numerical analysis for the study of the error in certain approximations and generalizes a similar result for a single variable previously obtained by the author [*Numerical quadrature* (Romanian), pp. 171–180, Editura Tehnică, Bucharest, 1957; MR 22 #B3149].

Berman, D. L. 3810

Some remarks on the problem of speed of convergence of polynomial operators. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika 1961, no. 5 (24), 3–5.

If $f(x)$ is a continuous periodic function and $u_n(f, x)$, $v_n(f, x)$ are two trigonometric polynomials of order n approximating f and converging uniformly to f as $n \to \infty$ and which coincide if f is a trigonometric polynomial of degree $\leq n$, then

$$C_1\|u_n(f, x) - f(x)\| \leq \|v_n(f, x) - f(x)\| \leq C_2\|u_n(f, x) - f(x)\|,$$

where C_1, C_2 are constants and $\|f\| = \max |f(x)|$.

R. G. Langebartel (Urbana, Ill.)

Xie, Ting-fan [Hsieh, Ting-fan] 3811

The best approximation of periodic differentiable functions by trigonometric polynomials.

Acta Math. Sinica 13 (1963), 162–169 (*Chinese*); *translated as Chinese Math.* 4 (1963), 179–187.

We denote by $C_{2\pi}$ the set of all continuous functions with period 2π, by $L_{2\pi}$ the set of all L-integrable functions with period 2π, and by T_{n-1} the set of all trigonometrical polynomials of order $n-1$. For $f(x) \in C_{2\pi}$, we set

$$E_n(f) = \min_{T_{n-1}} \max_x |f(x) - T_{n-1}(x)|,$$

and for $f(x) \in L_{2\pi}$, we set

$$E_n(f)_L = \min_{T_{n-1}} \int_0^{2\pi} |f(x) - T_{n-1}(x)|\,dx.$$

We write $K_r(t)=\sum k^{-r}\cos(kt-\frac{1}{2}r\pi)$ $(r>0)$. When $f(x)\in C_{2\pi}$ can be expressed as

$$f(x)=\frac{1}{2}a_0+\frac{1}{\pi}\int_0^{2\pi}K_r(x-t)\varphi(t)\,dt,\qquad \varphi(t)\in C_{2\pi},$$

we say that the function $f(x)$ has an rth derivative in the sense of Weyl, $f^r(x)=\varphi(x)$, where $f(x)$ is the rth-order integral of $\varphi(x)$. In this case, the conjugate function $\bar{f}(x)$ can be expressed as

$$\bar{f}(x)=\frac{1}{\pi}\int_0^{2\pi}\bar{K}_r(x-t)\varphi(t)\,dt,$$

in which

$$\bar{K}_r(t)=\sum k^{-r}\sin(kt-\tfrac{1}{2}\pi r).$$

If k is a natural number, we set

$$\omega_k(\delta,f)=\max_{|h|\le\delta}\max_x\left|\sum_{i=0}^{k}(-1)^{k-i}\binom{k}{i}f(x+ih)\right|.$$

In this note, the following three theorems are proved. Theorem 1: If $r>0$, and the function $f(x)$ has its rth derivative $f^{(r)}(x)\in C_{2\pi}$, then

$$E_n(f)\le\frac{4}{\pi}\frac{A_r}{n^r}E_n(f^{(r)}),\qquad E_n(\bar{f})\le\frac{4}{\pi}\frac{\bar{A}_r}{n^r}E_n(f^{(r)})$$
$$(n=1,2,\cdots),$$

in which A_r, $\bar{A}_r$ are constants dependent only on r.

Theorem 2: If $r>0$, $f(x)\in C_{2\pi}$, $\sum n^{r-1}E_n(f)<+\infty$, then $f(x)$, $\bar{f}(x)$ both have continuous rth derivatives $f^{(r)}(x)$, $\bar{f}^{(r)}(x)$ and

$$E_n(f^{(r)})\le C_r\left\{n^rE_n(f)+\sum_{\nu=n+1}^{\infty}\nu^{r-1}E_\nu(f)\right\},$$
$$E_n(\bar{f}^{(r)})\le\bar{C}_r\left\{n^rE_n(f)+\sum_{\nu=n+1}^{\infty}\nu^{r-1}E_\nu(f)\right\}$$
$$(n=1,2,\cdots),$$

in which C_r and $\bar{C}_r$ are constants dependent only on r.

Theorem 3: Under the hypotheses of Theorem 2, we have

$$\omega_k\left(\frac{1}{n},f^{(r)}\right)\le C_{k,r}\left\{\sum_{\nu=1}^{n}\nu^{k+r-1}E_\nu(f)+\sum_{\nu=n+1}^{\infty}\nu^{r-1}E_\nu(f)\right\},$$
$$\omega_k\left(\frac{1}{n},\bar{f}^{(r)}\right)\le\bar{C}_{k,r}\left\{\sum_{\nu=1}^{n}\nu^{k+r-1}E_\nu(f)+\sum_{\nu=n+1}^{\infty}\nu^{r-1}E_\nu(f)\right\}$$
$$(n=1,2,\cdots),$$

in which $C_{k,r}$ and $\bar{C}_{k,r}$ are constants dependent only on r and k. *F. C. Hsiang* (Taipei)

Krylov, V. I.; Janovič, L. A. 3812

On the convergence of a trigonometric interpolation for analytic periodic functions. (Russian)

Dokl. Akad. Nauk BSSR 7 (1963), 649–652.

Let z_n^k, $k=0,1,\cdots,2n$, $n=1,2,\cdots$, be arbitrary complex numbers in a closed region D contained in $|\mathrm{Im}(z)|\le h$, $0\le\mathrm{Re}(z)<2\pi$. The authors determine the smallest region containing D in which a 2π-periodic function f must be holomorphic in order that the sequence of trigonometric polynomials $\{T_n\}$ defined by $T_n(z_n^k)=f(z_n^k)$, $k=0,1,\cdots,2n$, $n=1,2,\cdots$, converges uniformly to f in the region D^* obtained by 2π-translations of D, for any choice of the nodes in D. A typical result is the following: If $D=\{z:|\mathrm{Im}(z)|\le d,\ 0\le\mathrm{Re}(z)<2\pi\}$, then a 2π-periodic function f should be holomorphic at least in the region $|\mathrm{Im}(z)|\le d+2\log(\cosh d+\sqrt{(1+\cosh^2 d)})$, in order that the sequence of trigonometric polynomials converges uniformly in $|\mathrm{Im}(z)|\le d$, for any choice of the nodes in D.

Similar results for polynomial interpolation have been established previously by V. I. Krylov [same Dokl. 78 (1951), 857–859; MR 13, 637]. *R. Bojanic* (Columbus, Ohio)

Pavlovskiĭ, N. M. 3813

A method of approximating differentiable functions by trigonometric polynomials. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, no. 4 (41), 118–125.

Let $MW^{(r)}$ be the class 2π-periodical continuous functions having absolutely continuous $(r-1)$st derivatives, and rth derivatives almost everywhere such that $|f^{(r)}(x)|\le M$. For $f(x)$ (with respect to its Fourier sum $S_n(f,x)$) the author defines

$$\sigma_n^N(f,x)=\frac{1}{N(n+1)}\sum_{k=1}^{N}f(x_k)\left[\frac{\sin\frac{1}{2}(n+1)(x-x_k)}{\sin\frac{1}{2}(x-x_k)}\right]^2,$$

where $x_k=2k\pi/N$, N is any positive integer satisfying $N\ge 2n+1$ (for $N=2n+1$, $\sigma_n^N(f,x)$ becomes the Fejér interpolation sum for $f(x)$). Following the method of Nikol'skiĭ [Trudy Mat. Inst. Steklov. 15 (1945), p. 25; MR 7, 435], the author shows that

$$\sup_{f\in MW^{(r)}}\sup_x|f(x)-\sigma_n^N(f,x)|=\frac{MC_r}{n}+O\left(\frac{1}{n^r}\right)\qquad(r\ge 2),$$
$$=\frac{2M}{\pi}\frac{\log n}{n}+O\left(\frac{1}{n}\right)\quad(r=1),$$

where

$$C_r=\frac{4}{\pi}\sum_{k=0}^{\infty}\frac{(-1)^{k(r-1)}}{(2k+1)^r}.$$

The O-term is due to an inequality of Jackson [Dissertation, Göttingen, 1911]. A more general result is obtained by utilizing an inequality of v. Sz. Nagy [Ber. Verh. Akad. Wiss. Leipzig 90 (1938), 103–134]. *C. V. Stanojevic* (Detroit, Mich.)

Sur les facteurs de convergence des séries de Walsh-Fourier.

Proc. Japan Acad. **40** (1964), 250–252.

An outline is given of proofs of a result that was stated by Paley [Proc. London Math. Soc. (2) **34** (1932), 241–264; ibid. (2) **34** (1932), 265–279] that for almost all x, $(\log k)^{-1/p}$, $1\le p\le 2$, is a factor of convergence of the Walsh series for $f\in L_p[0,1]$. For $p=2$, the proof had been given by Yano [Tôhoku Math. J. (2) **3** (1951), 223–242; MR 13, 550]. *P. Civin* (Eugene, Ore.)

Szegő, Gábor 3815

On bi-orthogonal systems of trigonometric polynomials. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 255–273 (1964).

This article, dedicated to Karl Loewner, introduces a set of trigonometric polynomials biorthogonal with respect to a prescribed weight function $w(\theta)$. They are generalizations of orthogonal polynomials defined on a finite interval and give rise to a theory generalizing classical Fourier series (for which $w(\theta)=1$). For this system, the author establishes recurrence relations, properties of zeros, a mechanical quadrature theorem, asymptotic behavior, a theorem on equiconvergence with ordinary Fourier series, etc. He initiates also a consideration of the analogous problems on the sphere, arising from the corresponding generalization of surface harmonics, and calls attention to the simplifications afforded by the "zonal" case, where the weight function depends on only one variable.

The function $w(\theta)$ is non-negative, of period 2π, Lebesgue integrable, and not equivalent to the zero function. If, in addition, $w(\theta)$ is even, then the bi-orthogonal system is composed of cosine and sine polynomials, respectively, and many of the results assume especial neatness. Another special case leading to noteworthy results is also discussed, namely, when $w(\theta)$ is the reciprocal of a positive trigonometric polynomial. *L. Lorch* (Edmonton, Alta.)

Dual series relations. I. Dual relations involving Fourier-Bessel series.

Proc. Roy. Soc. Edinburgh Sect. A **66** (1962/63), 150–160 (1964).

The dual series

$$\text{(A)}\quad \sum_{n=1}^{\infty} \lambda_n^{-p} a_n J_\nu(\rho\lambda_n) = f_1(\rho), \qquad 0 \le \rho < 1,$$
$$\sum_{n=1}^{\infty} a_n J_\nu(\rho\lambda_n) = f_2(\rho), \qquad 1 < \rho \le a,$$

where $\{\lambda_n\}$ are the positive zeros of the Bessel function $J_\nu(a\lambda)$ in increasing order, $-1 \le p \le 1$, $\nu \ge 0$, $f_1(\rho)$ and $f_2(\rho)$ prescribed, are solved for the unknown sequence $\{a_n\}$. This solution is the sum of the solution of (A) with $f_1(\rho)=0$ and of the solution of (A) with $f_2(\rho)=0$. The latter solutions are obtained by first giving an integral representation of a_n in terms of a function $g(t)$. It is then shown that $g(t)$ satisfies a Fredholm integral equation of the second kind. Solution of this equation yields the solution of the given problem. *A. E. Danese* (Buffalo, N.Y.)

Srivastav, R. P. 3817

Dual series relations. II. Dual relations involving Dini Series.

Proc. Roy. Soc. Edinburgh Sect. A **66** (1962/63), 161–172 (1964).

The dual series

$$\alpha c_0 \rho^\nu + \sum_{n=1}^{\infty} c_n \lambda_n^{\,p} J_\nu(\lambda_n\rho) = f_1(\rho), \qquad 0 \le \rho < c,$$
$$c_0 \rho^\nu + \sum_{n=1}^{\infty} c_n J_\nu(\lambda_n\rho) = f_2(\rho), \qquad c < \rho \le 1,$$

where $\{\lambda_n\}$ are the positive roots of $zJ_\nu'(z)+HJ_\nu(z)=0$, H is a real constant, $H+\nu \ge 0$ with $c_0=0$ if $H+\nu\ne 0$, $-1 \le p \le 1$, $\nu > -\frac12$, are solved for the unknown sequence $\{c_n\}$ using the same technique as in #3816 above.

A. E. Danese (Buffalo, N.Y.)

Srivastav, R. P. 3818

Dual series relations. III. Dual relations involving trigonometric series.

Proc. Roy. Soc. Edinburgh Sect. A **66** (1962/63), 173–184 (1964).

Dual series involving trigonometric series such as

$$\sum_{n=1}^{\infty} n^p a_n \sin nx = f_1(x), \qquad 0 \le x < c,$$
$$\sum_{n=1}^{\infty} a_n \sin nx = f_2(x), \qquad c < x \le \pi,$$

and

$$\sum_{n=1}^{\infty} [(n-\tfrac12)^p] a_n \cos(n-\tfrac12)x = f_1(x), \qquad 0 \le x < c,$$
$$\sum_{n=1}^{\infty} a_n \cos(n-\tfrac12)x = f_2(x), \qquad c < x \le \pi,$$

$0<c<\pi$, $-1<p<1$, are solved for $\{a_n\}$ using the same techniques as in #3816. Instances where the resulting integral equations have explicit analytical solutions are treated in detail. *A. E. Danese* (Buffalo, N.Y.)

Srivastav, R. P. 3819

Dual series relations. IV. Dual relations involving series of Jacobi polynomials.

Proc. Roy. Soc. Edinburgh Sect. A **66** (1962/63), 185–191 (1964).

The dual equations

$$\sum_{n=0}^{\infty} \frac{A_n}{\Gamma(\alpha+n+1)\Gamma(\beta+n+\frac12)} P_n^{(\alpha,\beta)}(\cos\theta) = f_1(\theta), \qquad 0 \le \theta < \varphi,$$
$$\sum_{n=0}^{\infty} \frac{A_n}{\Gamma(\beta+n+1)\Gamma(\alpha+n+\frac12)} P_n^{(\alpha,\beta)}(\cos\theta) = f_2(\theta), \qquad \varphi < \theta \le \pi,$$

where $\alpha > -\frac12$, $\beta > -1$, and $P_n^{(\alpha,\beta)}$ are the Jacobi polynomials, are solved for $\{A_n\}$ by essentially the same technique used in #3816. *A. E. Danese* (Buffalo, N.Y.)

Ul'janov, P. L. 3820

Series with respect to a Haar system with monotone coefficients. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **28** (1964), 925–950.

(I) Es sei $\{c_n\} \in A$, d.h. es sei $\{c_n\}$ eine positive, monoton abnehmende Folge. Ist

$$P(t) = \lim_{N\to\infty}\left(\sup_{2\le\nu\le N} \sum_{m=2}^{\nu} c_m\chi_m(x)\right)$$

integrierbar in $[0,1]$, dann ist die Haarsche Reihe $\sum c_m\chi_m(x)$ die Entwicklung einer Funktion $f(t)$, für die $f\in L^p[0,1]$ bei jedem $p\ (\ge 1)$ besteht. (II) $\bar{A}$ bezeichnet die Klasse der Folgen $\{b_m\}$ mit $\max_{2^n<m\le 2^{n+1}}|b_m| \le C\min_{2^{n-1}<m\le 2^n}|b_m|$ $(n=1,2,\cdots)$. Ist $\{b_m\}\in\bar{A}$ und gilt für die Partialsummen $s_n(x)$ der Reihe $\sum b_m\chi_m(x)$,

$$\limsup_{n\to\infty} |s_{q_n}(t)| < \infty$$

in einer Menge vom positiven Mass, wobei $\{q_n\}$ eine im strengen Sinne wachsende Folge der natürlichen Zahlen ist, dann gilt $\sum b_m^2 < \infty$. (III) Es sei $\{a_m\}\in A$. Ist die Reihe

$\sum a_m\chi_m(x)$ in einer Menge vom positiven Mass $|C_1 1|$-summierbar, dann gilt $\sum (a_m/\sqrt{m}) < \infty$.

K. Tandori (Szeged)

Freud, G.; Sallay, M. 3821

Sur la vitesse de convergence du développement selon des fonctions propres de Sturm-Liouville. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **6** (1961), 271–279.

Suppose $q(x)$ is continuous on $[0, \pi]$, and consider in that interval the differential equation $y''+[\lambda-q(x)]y=0$ with the boundary conditions (1) $a_0y(0)+b_1y'(0)=0$; $a_2y(\pi)+b_2y'(\pi)=0$. Denote by $\lambda_0, \lambda_1, \lambda_2, \cdots$ the eigenvalues, $v_0, v_1, v_2, \cdots$ the normalized eigenfunctions and $s_n(x, f)=\sum_{k=0}^{n} a_kv_k(x)$, where $a_k=\int_0^\pi f(x)v_k(x)\,dx$. Denote by $w_2(f, \delta)=\max_{|h|\le\delta, x\in(0,\pi)} |f(x+h)-2f(x)+f(x-h)|$.

Theorem 1: If $f(x)$ is continuous in $[0, \pi]$, satisfies conditions (1) and (2) $\begin{vmatrix} a_1 & b_1 \\ a_2 & a_2+b_2 \end{vmatrix} \ne 0$, then

$$|f(x)-s_n(x, f)| \le K_1 \log n[w_2(f, n^{-1})+K_2n^{-1} \max_{i=0,1} \|\delta^{(i)}f\|],$$

where

$$\begin{aligned} \delta^{(0)}f &= 0 && \text{for } b_1 = 0,\\ &= \frac{f(\pi/n)-f(0)}{\pi/n}-f'(0) && \text{for } b_1 \ne 0,\\ \delta^{(1)}f &= 0 && \text{for } b_2 = 0,\\ &= \frac{f(\pi)-f(\pi-\pi/n)}{\pi/n}-f'(\pi) && \text{for } b_2 \ne 0. \end{aligned}$$

(In case $b_1=b_2=0$, there is no requirement that f be differentiable at 0 and π.) K_1 and K_2 are constants which are independent of x, n, and f.

Suppose $f(x)$ and $q(x)$ possess continuous rth derivatives and denote by $L^{(i)}: i=0, 1, \cdots, k=[\frac{1}{2}(r-1)]$ the operators $L^{(0)}f=f$; $L^{(1)}f=f''-qf$; $\cdots$; $L_f^{(i)}=L^{(1)}(L^{(i-1)}f)$. Theorem 2: If f and q have continuous rth derivatives, $L^{(i)}f$, $i=1, 2, \cdots, k=[\frac{1}{2}(r-1)]$ satisfy conditions (1) and (2) holds, then

$$|f(x)-s_n(x, f)| \le O\left(\frac{\log n}{n^r}\right)[w_2(f^{(r)}, n^{-1}) + \frac{1}{n^2}\sum_{m=0}^{r}\|f^{(m)}\| + \frac{1}{n}\max_{i=0,1}\sum_{m=1}^{r}\|\delta^{(i)}f^{(m)}\|].$$

Sinha, S. R. 3823

A theorem on the absolute Cesàro summability of Fourier series.

Proc. Nat. Inst. Sci. India Part A **29** (1963), 302–308.

Let $F_k(t)$ denote the kth integral arithmetic mean in $(0, t)$ of $F(t)=\frac{1}{2}[f(x+t)+f(x-t)]$, k being a positive integer. The $(C, h>0)$ summability of the Fourier series of $F_k(t)$ at the point $t=0$ is known (Bosanquet) to be a necessary and sufficient condition for the Fourier series of $f(t)$ to be summable $(C, k+h)$ at $t=x$. The author proves an analogous result in which ordinary Cesàro summabilities (C, h) and $(C, k+h)$ are replaced by absolute Cesàro summabilities $|C, h|$ and $|C, k+h|$.

It is probable that in both cases the limitation $k=E(k)$ is inessential, and it should be possible to prove the same results for any $k>0$.

E. Kogbetliantz (New York)

Singh, T. 3824

Nörlund summability of Fourier series and its conjugate series.

Ann. Mat. Pura Appl. (4) **64** (1964), 123–132.

If

$$\varphi(t) = f(x+t)+f(x-t)-2f(x), \quad \Phi(t) = \int_0^t |\varphi(u)|\,du,$$

the author shows the following theorem. If (N, p_n) is a regular Nörlund method defined by a real, non-negative, monotonic non-increasing sequence $\{p_n\}$ such that $P_n=\sum_{k=0}^{n} p_k\to\infty$, then, if

$$\Phi(t) = o\left(\frac{p(t^{-1})}{P(t^{-1})}\right)$$

as $t\to 0$, the Fourier series of $f(t)$ at $t=x$ is summable (N, p_n) to $f(x)$. A corresponding theorem is also proved for the conjugate series. These generalize the earlier results.

G. Sunouchi (Sendai)

Lal, Shiva Narain 3825

On the absolute Nörlund summability of a Fourier series.

Arch. Math. **15** (1964), 214–221.

Let $\sum a_n$ be a given infinite series with the sequence of partial sums $\{s_n\}$. Let p_n be a sequence of constants, real or complex, and let us write

$$P_n = p_0+p_1+\cdots+p_n, \qquad P_{-1} = p_{-1} = 0.$$

The sequence-to-sequence transformation

$$t_n = \frac{1}{P_n}\sum_{\nu=0}^{n} p_{n-\nu}s_\nu, \qquad P_n \ne 0,$$

defines the sequence $\{t_n\}$ of Nörlund means of the sequence $\{s_n\}$ generated by the sequence of coefficients p_n. The series $\sum a_n$ is said to be summable $|N, p_n|$ if the sequence $\{t_n\}$ is of bounded variation, that is, the series $\sum |t_n-t_{n-1}|$ is convergent.

Let $f(t)$ be a periodic function with period 2π and integrable in the sense of Lebesgue in $(-\pi, \pi)$. Let its Fourier series be

$$\frac{1}{2}a_0+\sum_{n=1}^{\infty}(a_n \cos nx+b_n \sin nx).$$

The author proves the following theorem. Let (N, p_n) be a Nörlund transformation with p_n non-negative and non-increasing, $\lim_{n\to\infty} p_n=0$, $|\Delta p_n|$ non-increasing, and satisfying the condition

$$\text{(i)} \qquad \sum_{n=1}^{\infty} P_n{}^2n^{-2} \le C.$$

If $f(x)$ is a continuous, periodic function with period 2π, and if

$$\text{(ii)} \qquad \sum_{n=1}^{\infty} P_n^{-1}\omega(n^{-1})n^{-1/2} < \infty,$$

$$\text{(iii)} \qquad \sum_{n=1}^{\infty} n^{-1}\omega(n^{-\delta}) < \infty \qquad (0 < \delta < 1),$$

then the Fourier series of $f(x)$ is summable $|N, p_n|$, where $\omega(\eta)$ is the modulus of continuity of $f(x)$.
F. C. Hsiang (Taipei)

Kachroo, I. C. 3826
The harmonic summability of a series associated with Fourier series.
Univ. e Politec. Torino Rend. Sem. Mat. **22** (1962/63), 159–164 (1964).
Let $s_n(x)$ be the partial sums of the Fourier series of $f(x)$. Then the author shows that if $\int_0^t |(1/u)\int_0^u \varphi(v)\,dv|\,du = o(t/\log(1/t))$ and $\int_0^\pi \varphi(t) \operatorname{cosec} \frac{1}{2}t\,dt$ exists, then the series $\sum ((s_n(x)-s)/n)$ is harmonically summable at the point x, where $\varphi(t) = f(x+t)+f(x-t)-2s$. *G. Sunouchi* (Sendai)

Kachroo, I. C. 3827
On the matrix summability of the derived Fourier series.
Univ. e Politec. Torino Rend. Sem. Mat. **22** (1962/63), 165–170.
The author assumes that the function

$$g(t) = \psi_x(t)/4(\sin \tfrac{1}{2}t) - c$$

is of bounded variation in the neighbourhood of $t=0$ and absolutely continuous in (η, π) for any $0<\eta<\pi$. The function $g(t)-g(+0)$ is evidently absolutely continuous $(0,\pi)$ and hence the derived Fourier series is convergent. So the author's theorem is trivial. The author says that his theorem contains Rath's result, but the reviewer cannot agree with this, because Rath assumes only that $g(t)$ is of bounded variation in $(0, \pi)$. *G. Sunouchi* (Sendai)

Dolcher, Mario 3828
Su un criterio di convergenza uniforme per le successioni monotone di funzioni quasi-periodiche.
Rend. Sem. Mat. Univ. Padova **34** (1964), 191–199.
Oggetto della nota è un teorema di L. Amerio [Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **28** (1960), 147–152; ibid. (8) **28** (1960), 322–327; ibid. (8) **28** (1960), 461–466; MR **22** #6927], il quale afferma, sotto opportune ipotesi, la convergenza uniforme di una successione monotona di funzioni quasi-periodiche. L'autore, tenuto presente che tale teorema è del tipo di U. Dini, dà una nuova dimostrazione, utilizzando la così detta compattizzazione di Bohr della retta reale. *S. Cinquini* (Pavia)

On linear summability methods for double Fourier series and best approximations of continuous functions of two variables. (Ukrainian. Russian and English summaries)
Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 38–41.

Griffin, V. B. 3829b
On linear summability methods for Fourier series and best approximations of periodic functions of two variables. (Ukrainian. Russian and English summaries)
Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 151–155.

Both papers give estimates for the degree of approximation to a continuous function by the partial sums of its double Fourier series, transformed by a matrix $(\lambda_k^{(m)}{}_j^{(n)})$ in convergence-factor fashion. The (rather complicated) estimates are expressed in terms of the best approximations to the function by trigonometric polynomials and differences through fourth order of the λ's. The second paper also contains a necessary and sufficient condition for the summability of the Fourier series of a continuous function by the summation process generated by the λ's.

Hochstadt, Harry 3830
Laplace transforms and canonical matrices.
Amer. Math. Monthly **71** (1964), 728–736.
From the author's introduction: "The purpose of this article is to demonstrate the intimate connection between systems of differential equations and canonical matrices. In particular it will be shown, using only some basic concepts of differential equations and linear algebra, that for every matrix a similarity transformation can be found which will put the given matrix into the Jordan canonical form. Subsequently some special cases will be treated, in particular normal matrices. The method leads to a canonical form naturally and is also a constructive method. Although the basic results are not new, it is believed that the treatment is original."

Abdi, Wazir Hasan 3831
Application of q-Laplace transform to the solution of certain q-integral equations.
Rend. Circ. Mat. Palermo (2) **11** (1962), 245–257.
In the words of the author, "The object of this paper is to make use of the q-Laplace transform in the solution of certain q-integral equations similar to the classical Fredholm and Volterra-type integral equations. It is not proposed to study here the general theory of such equations, but it is only intended to show as to how the q-Laplace operator can sometimes be used with advantage in the solution of such equations". *V. P. Mainra* (Pilani)

Feinberg, Irwin 3832
Sur une équation de convolution.
C. R. Acad. Sci. Paris **258** (1964), 6331–6333.
Given $P(x) = \sum_{-N+1}^{N+1} P_k e^{2\pi ikx}$, $P_{-k} = P_k \geq 0$, the author considers the problem of finding $f(x) \geq 0$ such that $f(x) = \sum_{-N+1}^{N+1} f_k e^{2\pi ikx}$, $f_{-k} = \bar{f}_k$ and $|f_k|^2 = P_k$. This last condition is equivalent to $P(k) = f * \bar{f}$ and the positivity of f is equivalent to requiring a minimum for $|\int_{-1/2}^{1/2} f(x)\,dx|$. The minimization problem is taken up in further detail and

generalizations to distributions and n dimensions discussed.

★Z-Transformation. Theorie und Anwendung.

Theoretische Grundlagen der Technischen Kybernetik.

VEB Verlag Technik, Berlin, 1964. x+150 pp. *DM* 16.00.

Die schon von Laplace benutzte und in neuerer Zeit von den Ingenieuren wiederentdeckte Z-Transformation ordnet einer Originalfolge f_n die Bildfunktion $F^*(z) = \sum_{n=0}^{\infty} f_n z^{-n} \equiv Z\{f_n\}$, also eine außerhalb eines Kreises inklusive $z = \infty$ analytische Funktion zu. Verfasser stellt zunächst die theoretischen Grundlagen der Transformation (Abbildungsgesetze, Umkehrung) zusammen und behandelt dann folgende Anwendungen: (1) Lösung von linearen Differenzengleichungen mit konstanten Koeffizienten (als Beispiele Kettenleiter aus Vierpolen und die Summierung von Reihen). (2) Abtastsysteme für die beiden Fälle, daß der Eingang eine Impulsfolge und eine Folge von Rechteckpulsen ist, wobei als Übertragungsfunktion (Systemfunktion) im Sinne der Laplace-Transformation eine gebrochen rationale Funktion zugrunde gelegt wird. (3) Numerische Methoden: Wird ein Integral $y(t) = \int_0^t x(\tau)\,d\tau$ durch die Summe $y_1(nT) = T\sum_{k=0}^{n} x(kT)$ approximiert, so ist $Z\{y_1(nT)\} = TX^*(z)/(z-1)$. Diese einfache Bildfunktion führt zu einem übersichtlichen Algorithmus für die Summation. Hiervon werden Anwendungen gemacht auf die praktische Berechnung von Faltungsintegralen, wie sie in der Systemtheorie auftreten (der Ausgang eines Übertragungssystems ist gleich der Faltung von Eingang und Gewichtsfunktion), sowie auf die umgekehrte Laplace-Transformation von rationalen Funktionen ohne Kenntnis per Pole. Der Anhang enthält Tabellen für die Z-Bilder von Operationen an Folgen und die Z-Bilder von speziellen Folgen, sowie ein ausführliches Literatur-Verzeichnis. Alle theoretischen Entwicklungen werden durch numerische Beispiele illustriert, die vollständig durchgerechnet werden. Was die Ausstattung angeht, ist der Text in Maschinenschrift geschrieben. Das Buch ist die erste zusammenfassende Darstellung der Z-Transformation in deutscher Sprache.

Kober, H. 3835

On functional equations and bounded linear transformations.

Proc. London Math. Soc. (3) **14** (1964), 495–519.

From the author's introduction: "Functional equations of certain types are of importance in the theory of linear transformations, in analogy to the remarkable part which other types play in conformal mapping. Dirichlet's singular integral and Hilbert transforms, for instance, are operations W of the 'closed cycle': if $W(f) = W\{f(t); x\} = g(x)$, then

$$W\{f(t+a); x\} = g(x+a) \qquad (-\infty < a < \infty).$$

When $W\{f(t); s\} = g(s)$ is the Mellin transform,

$$W\{f(at); s\} = a^{-s}g(s) \qquad (0 < a < \infty).$$

The Fourier transformation $g(x) = T_0 f$ satisfies a number of equations,

$$(\alpha) \qquad T_0\{f(t+a); x\} = e^{iax}g(x),$$

$$(\beta) \qquad T_0\{f(at); x\} = |a|^{-1}g(x/a) \qquad (-\infty < a < \infty).$$

Conversely, if a Wf satisfies certain continuity conditions and the equation (α), then it is representable in the form $W\{f(t); x\} = \psi(x)T_0 f$, and if it satisfies both equations (α) and (β), then $Wf = cT_0 f$, where c is a complex constant, as will be shown (see § 9 of the paper).

"For both the Riemann-Liouville and the Weyl fractional integral W of order μ

$$(1) \qquad W\{f(at); x\} = a^{-\mu}g(ax) \qquad (0 < a < \infty),$$

and a similar equation holds for the modified fractional integrals; see earlier papers of the author [Quart. J. Math. Oxford Ser. **11** (1940), 193–211; MR **2**, 191; Proc. London Math. Soc. (3) **11** (1961), 434–456; MR **24** #A1025]; while for the transformations of the Fourier class, i.e., the sine transform and related ones

$$(2) \qquad W\{f(at); x\} = a^{-\nu}g(x/a) \qquad (0 < a < \infty).$$

There are numerous further examples.

"M. Plancherel [Proc. Cambridge Philos. Soc. **33** (1937) 413–418] used equation (2), with $\nu = 1$, which includes the 'general transforms', to deduce a group property of the operations concerned, provided that $f, g \in L^2(0, \infty)$. In a recent paper I have dealt with two wide classes of transformations which comprise most of the familiar operations and satisfy (1) for $\mu = 0$ or (2) for $\nu = 1$, and I have resorted to these equations in some proofs. In the present paper the general equations (μ, ν real) are discussed and are used systematically to obtain essential properties of the transformations. It will be shown that (1) and (2) imply functional equations between the transformations and their adjoints and that the latter equations lead to two-mappings rules. Again these turn out to be of considerable value for applications. A good insight is gained into the nature of well-known results, which incidentally are completed, and a number of further theorems are deduced, among them some on Stieltjes transforms."

Kober, H. 3836

An operator related to Hilbert transforms and to Dirichlet's integral.

J. London Math. Soc. **39** (1964), 649–656.

The author generalizes to L^p ($p > 1$) some results previously known for L^2 concerning the integral transform

$$\{B_a f\}(x) = \pi^{-1}\int_{-\infty}^{\infty} (t-x)^{-2} f(t) \sin a(t-x)\, dt$$

[see P. Heywood, same J. 28 (1963), 162–168; MR 26 #6680; and also R. Goldberg, ibid. 25 (1960), 200–204; MR 22 #1797]. In addition, he obtains some new formulas relating B_s not only to the Hilbert transform (as was done in the references cited above) but also to Dirichlet's singular integral and the integral transform

$$\pi^{-1}\int_{-\infty}^{\infty}(t-x)^{-1}\{1-\cos\alpha(t-x)\}f(t)\,dt$$

as well. The methods involve use of Hille's theory of H_p functions on the real axis.

R. R. Goldberg (Evanston, Ill.)

Varma, V. K. 3837

On further generalisation of the new transform.

Bull. Calcutta Math. Soc. 55 (1963), 79–87.

The author generalizes the Hankel transform given in the form

$$(1)\qquad f(x)=\int_0^\infty \psi^{\xi}_{\nu,\lambda}(xy)g(y)\,dy,$$

where

$$(2)\quad \psi^{\xi}_{\nu,\lambda}(x)=(1/\mu\mu')\int_0^\infty\int_0^\infty \sqrt{(xy/z)}J_\nu(xy/z)z^{1/\mu-3/2} \times y^{1/\mu'-1/2}\times J_\xi(y^{1/\mu'})J_\lambda(z^{1/\mu})\,dy\,dz,$$

$$0<\mu\leq 1,\quad 0<\mu'\leq 1,$$

still further and discusses special cases, as well as conditions under which the kernels enjoy the self-reciprocal property. The formulas involved are too complicated to be reproduced here.

★Generalized functions and direct operational methods. Vol. I: Non-analytic generalized functions in one dimension.

Prentice-Hall, Inc., Englewood Cliffs, N.J., 1964. xii+338 pp. $10.60.

The object of this book is to present an account of generalized functions and of their applications accessible to students with not much more than a knowledge of ordinary calculus. The present volume treats functions of one variable. The generalized functions considered form a space $\mathfrak{T}_+'$ of functionals on a space $\mathfrak{T}_-$ consisting of infinitely differentiable functions with support bounded above, and are defined, modifying procedures of Mikusiński and Temple, as weak limits of the functionals generated by sequences of piecewise continuous functions with support bounded below. The properties of these spaces necessary for the study of ordinary differential equations are developed, and important elementary examples of generalized functions—principal values, etc.—are treated in detail. A thorough account of the treatment of single ordinary differential equations, as well as systems, is given. There follows an account of the structure of generalized functions, leading to the proof that they are locally of finite order, and to proofs of the equivalence of the definitions given with those of Schwartz. Two final chapters deal with the Laplace transforms of generalized functions and with generalized Fourier series.

The author's exposition is careful both as regards rigour and in the selection of methods of proof adapted to his intended audience: The sections of the book directed to methods of solution of differential equations should be accessible to engineering students, and the whole requires nothing more than elementary real variable analysis; no use is made of complex function theory. The book should serve as an excellent introduction to its subject. It is accompanied by numerous exercises both on the text itself and on other lines of development. {Note a minor error in the determinantal formulae on p. 153.}

★*Z*-**Transformation. Theorie und Anwendung.**

Theoretische Grundlagen der Technischen Kybernetik.

VEB Verlag Technik, Berlin, 1964. x+150 pp. *DM* 16.00.

Die schon von Laplace benutzte und in neuerer Zeit von den Ingenieuren wiederentdeckte Z-Transformation ordnet einer Originalfolge f_n die Bildfunktion $F^*(z) = \sum_{n=0}^{\infty} f_n z^{-n} \equiv Z\{f_n\}$, also eine außerhalb eines Kreises inklusive $z = \infty$ analytische Funktion zu. Verfasser stellt zunächst die theoretischen Grundlagen der Transformation (Abbildungsgesetze, Umkehrung) zusammen und behandelt dann folgende Anwendungen: (1) Lösung von linearen Differenzengleichungen mit konstanten Koeffizienten (als Beispiele Kettenleiter aus Vierpolen und die Summierung von Reihen). (2) Abtastsysteme für die beiden Fälle, daß der Eingang eine Impulsfolge und eine Folge von Rechteckpulsen ist, wobei als Übertragungsfunktion (Systemfunktion) im Sinne der Laplace-Transformation eine gebrochen rationale Funktion zugrunde gelegt wird. (3) Numerische Methoden: Wird ein Integral $y(t) = \int_0^t x(\tau)d\tau$ durch die Summe $y_1(nT) = T\sum_{k=0}^{n-1} x(kT)$ approximiert, so ist $Z\{y_1(nT)\} = TX^*(z)/(z-1)$. Diese einfache Bildfunktion führt zu einem übersichtlichen Algorithmus für die Summation. Hiervon werden Anwendungen gemacht auf die praktische Berechnung von Faltungsintegralen, wie sie in der Systemtheorie auftreten (der Ausgang eines Übertragungssystems ist gleich der Faltung von Eingang und Gewichtsfunktion), sowie auf die umgekehrte Laplace-Transformation von rationalen Funktionen ohne Kenntnis per Pole. Der Anhang enthält Tabellen für die Z-Bilder von Operationen an Folgen und die Z-Bilder von speziellen Folgen, sowie ein ausführliches Literatur-Verzeichnis. Alle theoretischen Entwicklungen werden durch numerische Beispiele illustriert, die vollständig durchgerechnet werden. Was die Ausstattung angeht, ist der Text in Maschinenschrift geschrieben. Dahiya, R. S. 3842

A theorem in operational calculus. (German, French, and Italian summaries)

Mitt. Verein. Schweiz. Versich.-Math. **64** (1964), 175–181.

Derivation of a rule for one-sided Laplace integrals $\phi(p)=p\int_0^\infty \exp(-pt)f(t)\,dt$ according to which the transform ϕ of the function $x^{2\mu-\lambda}f(x)$ can be connected with that of $f(x)$ itself. The transform in question proves to be proportional to an integral over an hypergeometric function ${}_3F_2$ (Pochhammer's notation) with a factor containing five gamma functions in front of it. The derivation is given in a very concise form. Two applications of this rule lead to identities connecting the hypergeometric function ${}_3F_2$ with the other hypergeometric function ${}_2F_1$, and with the Legendre function $Q^n_{2\mu+n+1}$, respectively.

Hutson, V. 3843

Asymptotic solutions of integral equations with convolution kernels.

Proc. Edinburgh Math. Soc. (2) **14** (1964/65), 5–19.

The main portion of this paper is devoted to finding approximate solutions to integral equations of the form

$$(*)\qquad f(x) = \lambda\int_0^a k(x-t)f(t)\,dt,$$

where a is a large parameter. The basic assumptions are, roughly, that k is real, even, and exponentially small at infinity, and that the Fourier transform of k is strictly decreasing for positive values of the argument and has non-vanishing second derivative at 0. It is then shown that if λ lies in any finite range, then there is a τ_1 such that, uniformly on $0\le x\le a$,

$$f(x) = \phi(\min(x, a-x))+O(e^{-a\tau_1/2}),$$

where ϕ is the solution of the corresponding Wiener-Hopf equation ((*) with a replaced by ∞). An equation for the eigenvalues is also found, with a similar exponentially small error. These striking results justify the idea of Carrier [*50 Jahre Grenzschichtforschung*, pp. 13–20, Vieweg, Braunschweig, 1955; MR **18**, 693] that the solutions of (*) may be approximated by the solutions of the Wiener-Hopf equations, and contain as particular cases theorems of the reviewer [Trans. Amer. Math. Soc. **88** (1958), 491–522; MR **20** #4782; ibid. **100** (1961), 252–262; MR **25** #2420], which give weaker asymptotic results concerning only the largest eigenvalues of (*) and the corresponding eigenfunctions. The procedure is based on the observation of Latter [Quart. Appl. Math. **16** (1958), 21–31; MR **21** #2890] that, after taking Fourier transforms, (*) is equivalent to a pair of integral equations, and the asymptotic results are obtained by adroit but simple movement of the contours of integration.

H. Widom (Ithaca, N.Y.)

Williams, W. E. 3844

The solution of dual series and dual integral equations.

Proc. Glasgow Math. Assoc. **6** 123–129 (1964).

The equations

$$(1)\qquad L_1(x,\lambda)A(\lambda) = \varphi_1(x),\qquad \alpha<x<\beta,$$

$$(2)\qquad L_2(x,\lambda)A(\lambda) = \varphi_2(x),\qquad \beta<x<\gamma,$$

are symbolic equations for dual integral equations with $L_i(x,\lambda)=\int K_i(x,\lambda)A(\lambda)\,d\lambda$ and for dual series with $L_i(x,\lambda)=\sum_\lambda K_i(x,\lambda)A(\lambda)$, $i=1,2$, with φ_i, K_i, $i=1,2$, known functions. If L_1 and L_2 are operators with the properties (a) L_2^{-1} exists; (b) there exist operators M_1 and M_2 such that $M_1(x,u)f(u)=\int_a^x N_1(x,u)f(u)\,du$, $M_2(x,u,\delta)f(u)=\int_\delta^x N_2(x,u)f(u)\,du$, $\alpha<\delta\le\gamma$, N_1 and N_2 known functions, such that

$$L_1(x,\lambda)L_2^{-1}(\lambda,t)g(t) = M_1(x,u)M_2(u,v)g(v),\quad \alpha<x<\gamma,$$

then the determination of the solution of (1) and (2) formally reduces to the successive solution of two integral equations. (We have an analogous situation if L_1^{-1} rather than L_2^{-1} exists.) The author claims that all known types of dual integral and series equations are such that they determine a factorization of the above form and that this is the basis of all known methods (a variety of which exist as indicated in the references) for solving (1) and (2).

On the approximate solution of integral equations. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 749–753.

The author considers the Fredholm integral equation $u(P)=\lambda\int_{G_s}K(P,Q)u(Q)\,dQ+f(P)$, with G_s the s-dimensional unit hypercube, f and K periodic with period 1 in each variable, f from a given class, K with a given singularity at $P=Q$. At the points of a mesh, the integrals in the first l terms of the Neumann series for u (the iterated kernels are supposed to be known) are replaced by complicated sums of order N which are of the type considered by Korobov [*Number-theoretic methods in approximate analysis* (Russian), Fizmatgiz, Moscow, 1963; MR **28** #716]. The remainder is shown to satisfy, with an error of $O(N^{-\alpha+\varepsilon})$, $\varepsilon>0$, a certain linear algebraic system of order N_1 when l and N_1 are chosen in dependence of N; α is the exponent which determines the decrease of the Fourier coefficients of f.

Lando, Ju. K. 3847

A boundary-value problem for linear integro-differential equations of Volterra type in the case of disjoint boundary conditions. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1961**, no. 3 (22), 56–65.

The author applies a result of M. V. Keldyš [Dokl. Akad. Nauk SSSR **77** (1951), 11–14; MR **12**, 835] to obtain completeness and expansion theorems for the eigenfunctions

and associated functions of integro-differential equations of the form

$$u^{(n)}(x)+\sum_{i=0}^{n-2} a_i(x)u^{(i)}(x)+\sum_{i=0}^{n-1}\int_0^x A_i(x,t,\rho)u^{(i)}(t)\,dt + \rho^{n+1}\int_0^x u(t)\,dt = f(x),$$

under boundary conditions of the form

$$\sum_{k=0}^{n-1} \alpha_{jk}u^{(k)}(0) = 0 \qquad (j = 1, 2, \cdots, m),$$

$$\sum_{k=0}^{n-1} \beta_{jk}u^{(k)}(1) = 0 \qquad (j = m+1, m+2, \cdots, n).$$

F. Smithies (Cambridge, England)

Dombrovskaja, I. N.; Ivanov, V. K. 3848

Ill-posed linear equations and exceptional cases of equations of convolution type. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, no. 4 (41), 69–74.

The integral equation

$$(*)\quad \lambda\varphi(x)+\int_0^\infty k_1(x-t)\varphi(t)\,dt+\int_{-\infty}^0 k_2(x-t)\varphi(t)\,dt = f(x),$$

where $k_1(x), k_2(x) \in L(-\infty, \infty)$; $f(x), \varphi(x) \in L_2(-\infty, \infty)$ and $\lambda = \lambda_1$, $x > 0$, $\lambda = \lambda_2$, $x < 0$, was considered by Gahov and Smagina [Izv. Akad. Nauk SSSR Ser. Mat. **26** (1962), 361–390]. For such an equation the coefficient in the associated Riemann boundary problem may have zeros or poles on the real axis, in which case it will no longer be sufficient, for the solvability of (*), to have $f(x)$ orthogonal to all the solutions of the corresponding homogeneous adjoint equation (Noether's theorem). The authors confirm this fact employing methods of functional analysis and go on to supply an algorithm for approximating the solution of (*) in terms of Laguerre polynomials.

J. F. Heyda (King of Prussia, Pa.)

Gorbačuk, V. I. 3849

An integral representation of Hermitian indefinite kernels (the case of several variables). (Russian)

Ukrain. Mat. Ž. **16** (1964), 232–236.

On considère le domaine $G = G^{(1)} \times \cdots \times G^{(n)}$, $G^{(i)} = (a_i, b_i)$. Un noyau hermitien $K(x, y)$ est indéfini, à k carrés négatifs, si pour chaque m, la forme $\sum_{j,k=1}^m K(x_j, x_k)\xi_k\bar{\xi}_j$ $(x_j \in G^{(j)})$ a au plus k carrés négatifs, et au moins pour un m, exactement k carrés négatifs.

On désigne (a) par $L^{(i)}$ les expressions:

$$L^{(i)}u = \sum_{k=1}^{r_i} a_{k,i}d^ku/dt^k, \qquad t \in [a_i, b_i];$$

(b) par $P_i(t)$ les polynômes minimaux de $L^{(i)}$; (c) par

$$\Phi_i(x, y) = [P_i(L^{(i)})]_{x_i}[P_i(L^{(i)})]_{y_i}K(x, y) \quad (i = 1, 2, \cdots, n);$$

(d) par $\Phi(x, y) = \sum_1^n \Phi_i(x, y)$; (e) par $\chi_s^{(j)}(x_j, \lambda_j)$ $(s = 0, 1, \cdots, r_{j-1})$ un système fondamental de solutions de $L^{(j)}u = \lambda_j u$ $(x_j \in G^{(j)})$ satisfaisant à $\partial^k\chi_m(x_j, \lambda_j)/\partial x_j^k|_{x_j=a_j} = \delta_{mk}$; (f) par

$$X_\alpha(x, \lambda) = \chi_{\alpha_1}(x_1, \lambda_1)\cdots\chi_{\alpha_n}(x_n, \lambda_n).$$

Sous certaines conditions restrictives pour $L^{(i)}$, $K(x, y)$ admet la représentation:

$$K(x, y) = T_\rho(x, y) + \int_{E_n} \frac{\sum_{\alpha,\beta\in A}[X_\alpha(x, \lambda)\bar{X}_\beta(y, \lambda) - S_\rho^{(\alpha,\beta)}(\lambda; x, y)]}{\sum_1^n |P_i(\lambda_i)|^2}\, d\sigma_{\alpha\beta}(\lambda),$$

où $S_\rho^{(\alpha,\beta)}$ est une correction qui fait l'expression sous l'intégrale régulière et T_ρ une solution de

$$\sum_1^n [\bar{P}_i(L^{(i)})]_{x_i}[P_i(\bar{L}^{(i)})]_{y_i}u(x, y) = 0,$$

$d\sigma_{\alpha\beta}(\lambda)$ une matrice positive définie et A un domaine d'indices, convenablement choisis.

Mullikin, T. W. 3850

Chandrasekhar's X and Y equations.

Trans. Amer. Math. Soc. **113** (1964), 316–332.

The problem of radiative transfer in homogeneous plane-parallel atmospheres leads to certain X and Y functions, determined by two nonlinear integral equations. The solutions of these equations may be expressed by those of an auxiliary linear integral equation. A system of two simultaneous linear equations for X and Y is derived under specified assumptions, having a unique solution. It is then shown that X and Y satisfy a system of two singular linear integral equations. These are equivalent to a system of two Fredholm equations. These may be solved by interation, and this solution is elaborated. The solutions are expressed by means of an H-function, which may be computed.

Kelley, J. L.; Namioka, Isaac 3851

★Linear topological spaces.

With the collaboration of W. F. Donoghue, Jr., Kenneth R. Lucas, B. J. Pettis, Ebbe Thue Poulsen, G. Baley Price, Wendy Robertson, W. R. Scott, Kennan T. Smith. The University Series in Higher Mathematics. *D. Van Nostrand Co., Inc., Princeton, N.J.*, 1963. xv + 256 *pp.* \$8.00.

This book is the result of the efforts of many authors who happened to agree (in 1953) on how to arrange the theory of topological linear spaces in such a way as to make the more recent (at that time) results on duality appear as the natural consequences of the preliminary work. For example, having observed how a criterion of Shmulian's was used [the reviewer, Duke Math. J. **14** (1947), 787–794; MR **9**, 241] to improve a theorem of Mackey's, they make it one of the initial propositions of Chapter 5 (on duality, which occupies almost half the book) and use it systematically. By thus boldly, but properly, permuting the original order of entrance of basic ideas, they produced a body of ideas knit together by a few basic notions but possessing conspicuous concavities. Some of these they filled with such ideas as hypercompleteness and other concepts not

observed by the reviewer in any other text. Incidentally, this concept is due to J. L. Kelley, but characteristically, the text does not say so. To tell the truth, it is unfortunate that the authors found no recruit to take charge of documentation.

In a future edition we should have at least a reference from which Grothendieck's paper could be located [C. R. Acad. Sci. Paris 230 (1950), 605–606; MR 12, 715], and a reference (as given above) locating Mackey's and Shmulian's theorems. Then among other benefits, the reader would appreciate the authors' skill in reorganization and reformulation.

It is remarkable that such a joint effort should have produced such a valuable book, which will probably be the best text for a graduate course covering all that material, excepting operators in Hilbert space and topological linear algebras, which an aspirant to functional analysis ought to learn. This is in a large part due to the excellent and non-routine exercises, mainly added when the manuscript was revised in 1961.

Moreau, Jean Jacques 3852

★Étude locale d'une fonctionnelle convexe.

Université de Montpellier, Montpellier, 1963. 25 *pp.*

These mimeographed notes are a discussion of a general convex functional and its "gradient" in a linear topological space, sometimes taken as locally convex. The "gradient" is sometimes the strong or weak differential, or more generally a multiple-valued function defined by the slopes of supporting hyperplanes to the set of points above the graph. A number of "rules of calculation" of the gradient are given, including theorems on its existence and relationships with the conjugate (dual) convex functional of Fenchel. Special attention is given to the gradient of the sum of two convex functions, the Γ-convolution of two convex functions (i.e., the dual of the sum of their duals), and the inf-convolution, defined as

$$(f\nabla g)(x) = \inf_{u+v=x} [f(u)+g(v)],$$

which appears often in the theory of dynamic programming.

The spirit of the notes is a development in fuller detail and in slightly greater generality of earlier work of the author reported in a series of notes [cf., e.g., C. R. Acad. Sci. Paris 256 (1963), 5047–5049; MR 27 #4102].

Brøndsted, Arne 3853

Conjugate convex functions in topological vector spaces.

Mat.-Fys. Medd. Danske Vid. Selsk. 34, *no.* 2, 27 *pp.* (1964).

Let X and Y be paired topological linear spaces so that each is the dual of the other. For a real-valued function f with domain D in X one defines D' in Y as the set of all Y such that $xy-f(x)$ is bounded on D. One defines $f'(y)$ as $\sup(xy-f(x): x\in D)$. Then f' is the conjugate of f. The theory of convex conjugate functions was developed for finite-dimensional spaces by W. Fenchel, and extended independently by W. L. Jones and J. J. Moreau to infinite-dimensional spaces. Their investigations are continued, and to some extent, their results are included in the present paper.

Diaz, J. B.; Výborný, R. 3854

A mean value theorem for strongly continuous vector valued functions.

Czechoslovak Math. J. 14 (89) (1964), 322–323.

In this announcement the authors state the following mean value theorem, which is a generalization of the theorem proved by Aziz and Diaz [Contributions to Differential Equations 1 (1963), 251–269; MR 27 #247]. Suppose f is defined on $[a, b]$ with values in a normed vector space and suppose f is strongly continuous. Then there is a number $c\in(a, b)$ such that either, whenever both $h>0$ and $a\le c+h\le b$, one has

$$\left\|\frac{f(b)-f(a)}{b-a}\right\| \le \left\|\frac{f(c+h)-f(c)}{h}\right\|,$$

or, whenever both $h>0$ and $a\le c-h\le b$, one has

$$\left\|\frac{f(b)-f(a)}{b-a}\right\| \le \left\|\frac{f(c)-f(c-h)}{h}\right\|.$$

Edwards, R. E. 3855

Weak convergence of vector-valued series and integrals.

J. Austral. Math. Soc. 3 (1963), 159–166.

Let E, F, G be separated locally convex topological vector spaces such that $F\subset G$ and the injection map $i: F\to G$ is continuous. Let E', F', G' denote the respective duals of E, F and G. The paper discusses weak convergence of vector-valued series and integrals. The problem discussed in the case of series is concerned with the convergence of series of the type (1) $\sum_k\langle x, e_k'\rangle g_k$, where $x\in E$, $\{e_k'\}$ and $\{g_k\}$ are sequences of elements of E' and G, respectively. Under certain conditions, it is shown that the convergence of (1) for each $x\in E$ and for the weakened topology $\sigma(G, G')$ of G, each sum being in F, implies the convergence for the weakened topology $\sigma(F, F')$ of F.

A. Pietsch (Berlin)

Hayes, A. 3857

Sequentially pointwise continuous linear functionals.

Fund. Math. 55 (1964), 67–75.

Let E be a linear subspace of R^X, the linear space of all real-valued functions on a non-empty set X (R is the real line). A consequence of the duality theory of linear spaces is that each linear functional L on E which is continuous with respect to pointwise convergence, on X, of nets in E is of the form $L(f)=\sum_{i=1}^n \lambda_i f(x_i)$, where λ_i are n real numbers for some n, $f\in L$ and $x_i\in X$. The author shows that a similar result is true for linear lattices $E\subset R^X$ and linear functionals L which are continuous with

respect to pointwise convergence, on X, of sequences in E (or sequentially continuous). More specifically, he proves the following. Let L be a sequentially continuous linear functional on a linear lattice $E \subset R^X$. Then there exists a unique linearly independent family $S(L)$ of sequentially continuous lattice linear functionals, or the negative of lattice linear functionals, such that for each $f \in E$, $L'(f) = 0$ for all but a finite number of L' in $S(L)$ and $L(f) = \sum\{L'(f): L' \in S(L)\}$. He also shows that under strengthened conditions $S(L)$ is finite. Whether or not $S(L)$ is infinite is not known. Similar results for lattice algebras are also derived. As the author points out, results closely related to these have also been obtained by J. R. Isbell and E. S. Thomas, Jr. [Proc. Amer. Math. Soc. **14** (1963), 644–647; MR **27** #1816] under stronger hypotheses.

Keller, H. H. 3858

Differenzierbarkeit in topologischen Vektorräumen.

Comment. Math. Helv. **38** (1964), 308–320.

This paper is concerned with the generalization of the notions of the Gâteaux and Fréchet derivatives to functions defined between Hausdorff real linear topological spaces which are usually (but not always) locally convex. Several notions of differentiability are considered pertaining to different conditions on the approach of the remainder term to zero. The interrelation between these types of remainder terms is analyzed, and the usual formulas and results concerning differentiability are extended under various conditions which are too complicated to describe here. *R. G. Bartle* (Urbana, Ill.)

Kruse, Arthur H. 3859

Badly incomplete normed linear spaces.

Math. Z. **83** (1964), 314–320.

A normed linear space is said to be subcomplete provided it is the image of a Banach space under a continuous linear transformation (or, equivalently, a biunique continuous linear transformation). And Y is said to be badly incomplete provided every subcomplete subspace is of smaller dimension than Y. The paper is motivated by an earlier observation that if X is a separable normed linear space and L is an infinite-dimensional Banach space, then there exists a biunique continuous linear transformation of X into L. Of course, this may fail when "Banach" is replaced by "normed linear", for then it may happen that $\dim X = c > \dim L$. The author's Theorem A shows that the failure may occur even when $\dim L = c$. Indeed, each separable infinite-dimensional Banach space Y contains 2^c linear subspaces L such that whenever T is a continuous linear transformation of a Banach space X into Y, then (a) $\dim T(X) < \aleph_0$ if $T(X) \subset L$, and (b) $\dim (L \cap T(X)) = c$ if $\dim T(X) \geq \aleph_0$. In particular, $\dim L = c$ and L is badly incomplete. Theorem A is generalized in various ways which are too technical to describe here.

Some of the author's constructions, lemmas and corollaries are of independent interest. In particular, he shows that a linear space Y is a Banach space (or alternatively, a Hilbert space) under some norm if and only if $\dim Y < \aleph_0$ or $(\dim Y)^{\aleph_0} = Y$. This implies a theorem of Goffman [Bull. Amer. Math. Soc. **49** (1943), 611–614; MR **5**, 149] to the effect that if the generalized continuum hypothesis holds, then a linear space Y is Banach-normable if and only if $\dim Y$ is not the limit of a strictly increasing sequence of cardinal numbers.

Victor Klee (Seattle, Wash.)

Mirman, B. A. 3860

A basis criterion in Hilbert space. (Russian)

Sibirsk. Mat. Ž. **4** (1963), 1433–1435.

The author proves various forms of a criterion stating that a minimal double total set $\{\varphi_i\}$ [see S. Kaczmarz and H. Steinhaus, *Theorie der Orthogonalreihen*, Monogr. Mat., Band 6, Warsaw, 1935] of elements in a separable Hilbert space H be a basis. A criterion due to M. M. Grinbljum [Dokl. Akad. Nauk SSSR **31** (1941), 428–432; MR **3**, 49] is used in the proofs. A formulation of the author's criterion is of interest, which consists in a translation of that criterion to the uniform boundedness of secants of (maximal) angles between the closed subspaces L_n and G_n of H determined by the n first elements of $\{\varphi_i\}$ and the n first elements of the corresponding biorthogonal set $\{\psi_i\}$. This work may be applied to simplify some proofs in the papers of N. K. Bari [Moskov. Gos. Univ. Učen. Zap. **148** (1951), Mat. 4, 69–107; MR **14**, 289] and K. I. Babenko [Dokl. Akad. Nauk SSSR **62** (1948), 157–160; MR **10**, 249]. A closely related result may be found in the paper by M. M. Grinbljum and L. A. Gurevič [ibid. **30** (1941), 287–289; MR **2**, 313].

Orihara, Masae 3861

Linear functionals on a Banach space with semi-norms.

Yokohama Math. J. **11** (1963), 13–22.

A "many-norms space" (as defined in an earlier paper [same J. **10** (1962), 1–4; MR **27** #2830]) is a Banach space $\langle X, \|\ \|\rangle$ provided with a family $\|\ \|_\alpha$ $(\alpha \in \Lambda)$ of semi-norms such that $\|x\| = \sup \|x\|_\alpha$ for every x in X. The author continues the work and asserts fourteen theorems and propositions.

{Reviewer's comments: Both papers contain a peculiar mixture of known facts and false statements. Specifically, Proposition 2 of the paper under review (asserting that if $\|x_n - x\|_\alpha^* \to 0$ for each $\alpha \in \Lambda$, then the norms $\|x_n\|$ are bounded) is false, and the other theorems and propositions are known (and proved in essentially the same form in papers quoted by the author and in papers by A. Grothendieck [C. R. Acad. Sci. Paris **230** (1950), 605–606; MR **12**, 715] and A. Alexiewicz and the reviewer [Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **6** (1958), 135–139; MR **20** #6643]). The full list of errors is too long to be quoted here.} *Z. Semadeni* (Poznań)

Ruckle, William H. 3862

The infinite sum of closed subspaces of an F-space.

Duke Math. J. **31** (1964), 543–554.

The first part of this paper studies various conditions under which the sum of a collection of closed linear subspaces of an F-space will be closed. The second part is a discussion of Schauder decompositions of an F-space. A sequence $\{M_i\}$ of closed linear subspaces of an F-space X with $\sum_{i=1}^\infty M_i = X$ is called a Schauder decomposition of X if $x_i \in M_i$ $(i = 1, 2, \cdots)$ and $\sum_{i=1}^\infty x_i = 0$ imply $x_i = 0$ for each i. The final part of the paper deals with boundedly

complete Schauder decompositions, i.e., Schauder decompositions $\{M_i\}$ of X having the property that for each sequence $\{x_i\}$ with $x_i \in M_i$ ($i = 1, 2, \cdots$), the convergence of the series $\sum_{i=1}^{\infty} x_i$ in X is equivalent to the boundedness of the sequence of the partial sums $\sum_{i=1}^{n} x_i$ ($n = 1, 2, \cdots$).

Ky Fan (Evanston, Ill.)

Simons, S. 3863

Boundedness in linear topological spaces.

Trans. Amer. Math. Soc. **112** (1964), 169–180.

The author introduces and proves equivalent two classifications of locally bounded linear topological spaces, i.e., spaces in which there is a bounded neighbourhood of the origin. First, if $0 < k \leq 1$, a (non-trivial) non-negative function f defines a k-pseudometric on a vector space X (on putting $\rho(x, y) = f(x-y)$) if and only if $f(x+y) \leq f(x)+f(y)$ and $f(\lambda x) = |\lambda|^k f(x)$ for all scalars λ and all x, y in X. It is proved that X is locally bounded if and only if its topology is defined by a k-pseudometric; the upper bound p of such k is called the type of the space X. Secondly, a (non-trivial) non-negative function g on a vector space X is a quasi-seminorm if and only if $g(\lambda x) = |\lambda| g(x)$ and, for some fixed b, $g(x+y) \leq b(g(x)+g(y))$ for all scalars λ and all x, y in X. The smallest such b is the multiplier of g. Again, X is locally bounded if and only if its topology is defined by a quasi-seminorm; the lower bound β of multipliers b of such quasi-seminorms is called the multiplier of X. The author shows that $\beta = 2^{(1/p)-1}$.

A linear topological space is called an upper bound space if and only if its topology is the upper bound of a family of locally bounded topologies, or, equivalently, defined by a family (f_j) of continuous k_j-pseudometrics. It is shown that such a space X has the useful property that a subset B is bounded if and only if each $f_j(B)$ is bounded.

Stampacchia, Guido 3864

Formes bilinéaires coercitives sur les ensembles convexes.

C. R. Acad. Sci. Paris **258** (1964), 4413–4416.

A generalization of a theorem of Lax and Milgram [*Contributions to the theory of partial differential equations*, pp. 167–190, Princeton Univ. Press, Princeton, N.J., 1954; MR **16**, 709] is presented. Let U be a closed convex subset of a real Hilbert space X and for $u \in U$ let $V(u) = \{v \in X : u + \varepsilon v \in U$ for some $\varepsilon > 0\}$. If $a(u, v)$ is a real continuous bilinear form on $X \times X$ which satisfies $a(u, u) \geq c\|u\|^2$, $c > 0$, for all $u \in X$, and if f is in the strong dual of X, then there exists a unique $u \in U$ such that $a(u, v) \geq f(v)$ for all $v \in V(u)$. Applications are given in the completion of the space of continuously differentiable functions on $\bar{\Omega}$, the closure of a bounded open set in R_n, with respect to the norm determined by the sum of the $L_2(\Omega)$ norms of functions and their first partial derivatives.

Veic, B. E. 3865

Some characteristic properties of unconditional bases. (Russian)

Dokl. Akad. Nauk SSSR **155** (1964), 509–512.

Let $\{x_k\}$ be a basis of a Banach space E; let $f_i \in E'$ be such that $f_i(x_k) = \delta_{ik}$. The author states (partly with short proofs) various conditions which are necessary and sufficient for $\{x_k\}$ to be an unconditional basis. Some of them are (1) for any $n_1 < n_2 < \cdots$, the closed subspace generated by $\{x_{n_k}\}$ is complemented; (2) for some M, $\|\sum_1^{\infty} f_k(x) x_k\| \leq M \|\sum_1^{\infty} |f_k(x)| x_k\|$ for all $x \in E$; (3) for some m, M,

$$m\left\|\sum_1^n |f_k(x)| x_k\right\| \leq \left\|\sum_1^n f_k(x) x_k\right\| \leq M\left\|\sum_1^n |f_k(x)| x_k\right\|$$

for all $x \in E$ and all $n = 1, 2, \cdots$; (4) $\{x_k\}$ is "Φ-stable", which means that $\{u_k\}$ is a basis whenever $\sum \|u_k - x_k\| \|f_k\|$ converges and u_k are independent in the sense that $\sum c_k u_k$ cannot converge to 0 unconditionally unless $c_k = 0$, $k = 1, 2, \cdots$.

Mitjagin, B. S.; Švarc, A. S. 3866

Functors in categories of Banach spaces. (Russian)

Uspehi Mat. Nauk **19** (1964), no. 2 (116), 65–130.

The categories $\mathfrak{K}$ studied here all have Banach spaces as the objects of the category and the linear continuous mappings as the mappings of the category. $\mathfrak{B}$, $\mathfrak{R}$, and $\mathfrak{H}$ are, respectively, the categories of all Banach spaces, all reflexive Banach spaces, and all Hilbert spaces. If X and $Y \in \mathfrak{K}$, then $(X \to Y)$ will represent the Banach space of all linear continuous mappings from X into Y. Attention is restricted to covariant functors of one variable. Examples are (1) Ω_A defined by: for each X in K, $\Omega_A(X) = (A \to X)$; for each α in $(X \to Y)$ and γ in $(A \to X)[\Omega_A(\alpha)](\gamma) = \alpha \circ \gamma$ (functional composition); (2) Σ_A defined by: for each X in K $\Sigma_A(X) = A \hat{\otimes} X$ (tensor product completed under the greatest cross norm); for each α in $(X \to Y)$ $\Sigma_A(\alpha) = 1_A \hat{\otimes} \alpha$; (3) l^p defined by: for each X in K $l^p(X)$ is the space of sequences $x = \{x_n\}$ of elements of X such that $\|x\| = (\sum \|x_n\|^p)^{1/p} < \infty$; for each α, $[l^p(\alpha)](x) = \{\alpha(x_n)\}$.

A category $\mathfrak{K}$ is regular if $X \in \mathfrak{K}$ implies $X^* \in \mathfrak{K}$. $\mathfrak{K}$ is reflexive if also each object X of $\mathfrak{K}$ is a reflexive Banach space, $X^{**} = X$.

A mapping T between functors F and H on a category $\mathfrak{K}$ is a family of linear continuous functions T_X, one for each object X of the category, such that $\sup_X \|T_X\| < \infty$, for each X in $\mathfrak{K}$, $T_X \in (F(X) \to H(X))$, and for each α in $(X \to Y)$ the diagram commutes:

$$\begin{array}{ccc} F(X) & \xrightarrow{T_X} & H(X) \\ {\scriptstyle F(\alpha)}\downarrow & & \downarrow{\scriptstyle H(\alpha)} \\ F(Y) & \xrightarrow{T_Y} & H(Y) \end{array}$$

(For example, every τ in $(A \to B)$ determines and is determined by a mapping T between the functors Σ_A and Σ_B.)

Functors F and G are called isometric [isomorphic] if every T_X is an isometry [isomorphism]. A functor G is dual to F, $G = \mathcal{D}F$, if for each A in K, $G(A) = (F \to \Sigma_A)$ and if for each γ in $(F \to \Sigma_A)$, α in $(A \to B)$ and object X in K,

$$[G(\alpha)\gamma]_X \simeq [1_X \hat{\otimes} \alpha]\gamma.$$

Theorem 1: For each two functors F and G the spaces of mappings $(F \to \mathcal{D}G)$ and $(G \to \mathcal{D}F)$ are isometric.

A functor F is reflexive if the natural isomorphism of F into $\mathcal{D}\mathcal{D}F$ is onto. Direct and inverse limits of "spectra" of functors are defined. Theorem 4: If F is the inductive limit of $(F_\alpha, \Pi_\alpha^\beta)$, then $\mathcal{D}F$ is the projective limit of $(\mathcal{D}F_\alpha, \partial\Pi_\alpha^\beta)$. Theorem 5 [6]: Each [reflexive] functor is an

inductive limit of functors of type Ω_A [type Σ_A]. Theorem 9: In a regular category, for each functor F, $\mathcal{D}F$ is a subfunctor of U, where, for each X in K, $U(X)=[F(X^*)]^*$.

This takes us by sampling through § 5 of the paper. § 6 is concerned with ideals in the commutative normed algebra m of bounded numerical sequences, with the functors defined by these ideals of m, such as l^p, and with cases where the dual of such a sequence functor is again a sequence functor.

§ 7, functors in categories of Hilbert spaces, starts with a fixed Hilbert space and discusses "normed ideals" Ω in the ring $\Omega_H(H)=(H\to H)$. The first part of the section matches ideals in m with symmetric ideals in $\Omega_H(H)$, so that l^1 corresponds to the class of nuclear operators and l^2 to the Hilbert-Schmidt class. In general, left normed ideals determine and are determined by functors and (Theorem 16) the dual to a functor determined by a left ideal Φ is the functor determined by an appropriately defined dual ideal Φ'.

§ 8 has results paralleling those of § 6, but beginning with Lebesgue measurable functions instead of sequences. § 9 describes the spaces of mappings of some of these functors into themselves. § 10 discusses Hilbert functors, which are defined in terms of the tensor square of T. Examples are l^2 and L^2 from §§ 6 and 8. § 11 tells of some interesting problems which still remain open.

Mac Nerney, J. S. 3867

Note on successive approximations.

Rend. Circ. Mat. Palermo (2) **12** (1963), 87–90.

This note proves a fixed-point theorem in an abstract setting. M is a complete metric space with metric Δ; S is a nondegenerate linearly ordered space; $D(c)$ is a class of functions γ on S to the non-negative reals satisfying the condition $\gamma(x)\ge\gamma(y)\ge\gamma(c)=0$ if $x\ge y\ge c$ or $x\le y\le c$; $F(c,A)$ is a class of functions on S to M such that $F(A)=c$, closed under uniform convergence on every interval of S and such that for each pair $u(x)$, $v(x)$ of $F(c,A)$ there exists a $\gamma(x)$ in $D(c)$ with $\Delta(u(x),v(x))\le\gamma(x)$ for x in S; $K[u]$ is an operation on $F(c,A)$ to $F(c,A)$ satisfying a Lipschitz-type condition, i.e., there exists a $\lambda(x)$ in $D(c)$ such that $\Delta(u(x),v(x))\le\gamma(x)$ implies $\Delta(K[u,x],K[v,x])\le L\int_c^x\gamma\,d\chi$, for each x in S, with $L\int$ the left Cauchy-Stieltjes integral; then there exists a unique U in $F(c,A)$ such that $K[U]=U$. The U is obtained by iteration. A generalization of the existence theorem for systems of linear differential equations, the theorem extends results of the author [Illinois J. Math. 7 (1963), 148–173; MR **26** #1726].

Merklen, Héctor 3868

Tensor product of ordered vector spaces. (Spanish)

Univ. Nac. Ingen. Inst. Mat. Puras Apl. Notas Mat. **2** (1964), 41–57.

Let X and Y be vector spaces over the real field preordered by positive cones ξ and η, respectively. A preorder ζ in the tensor product $Z=X\otimes Y$ is compatible with (X,ξ) and (Y,η) provided ζ is $w(Z,Z^*)$-closed and $\pi(\xi\times\eta)\subset\zeta$, where π is the canonical mapping $(x,y)\to x\otimes y$. The cone ζ_π made up of the weakly closed conical hull of $\xi\otimes\eta$ is called the projective cone of $X\otimes Y$. If ξ^* and η^* are the sets of positive linear forms on X and Y, then the biprojective cone ζ_ϵ of Z is defined to be the weakly closed conical hull of the set

$$\{\sum x_i\otimes y_i\,|\,\sum f(x_i)g(y_i)\ge 0,\quad \forall_{f\in\xi^*},\quad \forall_{g\in\eta^*}\}.$$

Both of these cones are compatible. The author proves a number of immediate results concerning these cones. He also shows that the biprojective cone of $X^*\otimes Y^*$ is related in a very natural way to the projective cone of $X\otimes Y$. He notes that the space of linear transformations $T:X\to Y$ with finite range can be identified with $X^*\otimes Y$ and shows that in $X^*\otimes Y$ the natural positive cone, that is, the one composed of T such that $T(\xi)\subset\eta$, is the biprojective cone of $X^*\otimes Y$. Similar results are found for operators $T:X\to Y^*$ and $T:X^*\to Y$. Finally, if Q_i $(i=1,2)$ is a compact Hausdorff space and $C(Q_i)$ is the ordered vector space of continuous functions on Q_i, then the order induced on $C(Q_1)\otimes C(Q_2)$ by that in $C(Q_1\times Q_2)$ is the biprojective order.

Granirer, Edmond 3870

A theorem on amenable semigroups.

Trans. Amer. Math. Soc. **111** (1964), 367–379.

A left- [right-] invariant mean for a semigroup G is a positive linear functional of norm 1 on the Banach space $m(G)$ of bounded real functions on G with the supremum norm that is invariant under left [right] translations. The main result of the paper is that if the two linear manifolds spanned respectively by the left- and the right-invariant means for G are non-trivial and finite-dimensional, then each is of dimension 1, G contains a finite group that is a two-sided ideal, and the left-invariant mean M is of the form $f\to\sum_{g\in G}\alpha(g)f(g)=M(f)$, where $f\in m(G)$ and $\alpha:G\to\mathbf{R}$ is such that $\sum_{g\in G}|\alpha(g)|<\infty$. This sharpens a result of Luthar [Illinois J. Math. **3** (1959), 28–44; MR **21** #2184]. For countable semigroups the author has deduced the same conclusions from weaker assumptions [ibid. 7 (1963), 32–48; MR **26** #1744]. In the spirit of a conjecture of Civin and Yood [Pacific J. Math. **11** (1961), 847–870; MR **26** #622] it is deduced that, for any commutative semigroup G without finite ideals, the Banach algebra $m(G)^*$ (the second dual of the convolution algebra $l_1(G)$) has infinite-dimensional radical.

Persson, Arne 3871

Compact linear mappings between interpolation spaces.

Ark. Mat. **5**, 215–219 (1964).

Two Banach spaces E_0 and E_1 form an interpolation pair if they are continuously imbedded in some separated

linear topological space $\mathscr{E}$. If A_0, A_1 and E_0, E_1 are interpolation pairs in $\mathscr{A}$ and $\mathscr{E}$, respectively, then A_θ, E_θ are called interpolation spaces of exponent θ $(0<\theta<1)$ with respect to A_0, A_1 and E_0, E_1 if the topological inclusions $A_0\cap A_1\subset A_\theta\subset A_0+A_1$ and $E_0\cap E_1\subset E_\theta\subset E_0+E_1$ hold and if each linear mapping T from $\mathscr{A}$ into $\mathscr{E}$ which maps A_i continuously into E_i $(i=0,1)$ maps A_θ continuously into E_θ such that

$$\|T\|_{A_\theta\to E_\theta}\leq\|T\|_{A_0\to E_0}^{1-\theta}\cdot\|T\|_{A_1\to E_1}^{\theta}.$$

For given pairs A_0, A_1 and E_0, E_1 there exist respective minimal and maximal interpolation spaces $\underline{A}_\theta$, $\underline{E}_\theta$ and $\bar{A}_\theta$, $\bar{E}_\theta$ [see J. L. Lions and J. Peetre, Inst. Hautes Études Sci. Publ. Math. No. 19 (1964), 5–68; MR 29 #2627]. The following condition plays an important rôle in the main theorem: (H) There exists to each compact set $K\subset E_0$ a constant C and a set $\mathscr{P}$ of linear operators $P:\mathscr{E}\to\mathscr{E}$ which map E_i into $E_0\cap E_i$ $(i=0,1)$ and are such that $\|P\|_{E_i\to E_i}\leq C$ $(i=0,1)$. Furthermore, there exists to each $\varepsilon>0$ a $P\in\mathscr{P}$ such that $\|Px-x\|_{E_0}<\varepsilon$ for all $x\in K$.

The following theorem is proved. Let A_0, A_1 and E_0, E_1 be interpolation pairs, A_θ, E_θ interpolation spaces of exponent θ $(0<\theta<1)$ with respect to these pairs and $A_\theta\subset\bar{A}_\theta$. If, furthermore, E_0, E_1 satisfy (H), $T:A_0\to E_0$ is compact and $T:A_1\to E_1$ is bounded, then $T:A_\theta\to E_\theta$ is compact. It is also shown that the interpolation pairs L^{p_0}, L^{p_1} $(p_0<\infty)$ and L_0^{∞}, L^{p_1} satisfy an approximation hypothesis even stronger than (H). Here L^p denotes the Banach space of all measurable functions on a locally compact space for which $\int|f|^p\,d\mu(x)<\infty$ (μ a positive measure) and L_0^{∞} is the closed subspace of L^{∞} which consists of all bounded measurable functions vanishing at infinity. *G. Goes* (Chicago, Ill.)

Pták, Vlastimil 3872

An extension theorem for separately continuous functions and its application to functional analysis.

Comment. Math. Univ. Carolinae **4** (1963), 109–116.

Let S, T be two completely regular spaces. A real-valued function f on $S\times T$ is said to satisfy the double limit condition if it is impossible to find two sequences $\{s_i\}\subset S$ and $\{t_j\}\subset T$ such that both $\lim_i\lim_j f(s_i,t_j)$ and $\lim_j\lim_i f(s_i,t_j)$ exist and are different. Let $C(S)$ be the Banach space of all real-valued, bounded continuous functions on S, and denote by $C(S)'$ the dual space of $C(S)$ topologized with the weak star topology. As S may be identified with a subset of $C(S)'$, $S\times T$ is imbedded in the topological vector space $C(S)'\times C(T)'$. The main theorem states that a real-valued, bounded, separately continuous function f on $S\times T$ can be extended to a separately continuous bilinear form on $C(S)'\times C(T)'$, if and only if f satisfies the double limit condition. The proof is based on a combinatorial lemma on convex means given in another paper [Proc. Sympos. Pure Math., Vol. VII, pp. 437–450, Amer. Math. Soc., Providence, R.I., 1963; MR 28 #4337], where the author proved a weaker version of the above theorem and discussed its relationship to a number of known results (e.g., theorems of Krein and Eberlein) on weak compactness. An earlier version of the combinatorial lemma (also due to the author) and its use in a proof of Krein's theorem are well known and can be found in the book of G. Köthe [*Topologische lineare Raume*, I, pp. 329–333, Springer, Berlin, 1960; MR 24 #A411]. *Ky Fan* (Evanston, Ill.)

Riedrich, Thomas 3873

Die Räume $L^p(0,1)$ $(0<p<1)$ sind zulässig.

Wiss. Z. Techn. Univ. Dresden **12** (1963), 1149–1152.

The author defines a sequence of mappings of $L^p(0,1)$ $(0<p<1)$ to its finite-dimensional subspaces which converges uniformly to the identical mapping on every compact subset. This shows that the metric linear spaces $L^p(0,1)$ are admissible [cf. V. Klee, Math. Ann. **141** (1960), 286–296; MR 24 #A1004]. *I. G. Amemiya* (Sapporo)

Riedrich, Thomas 3874

Der Raum $S(0,1)$ ist zulässig.

Wiss. Z. Techn. Univ. Dresden **13** (1964), 1–6.

Let E be a Hausdorff linear space, T a topological space, and f a mapping of T into E. Then f is called "compact" provided fT is a relatively compact subset of E, "finite" provided f is compact and fT lies in a finite-dimensional linear subspace of E, and "uniformly finitely approximable" provided f can be approximated uniformly on T by means of finite mappings. The space E is called "admissible" (zulässig) provided the injection in E of any compact subset of E is uniformly finitely approximable. Every locally convex space is admissible [Nagumo, Amer. J. Math. **73** (1951), 497–511; MR 13, 150]. For an arbitrary E, the Leray-Schauder theory can be developed for mappings $\Phi:X\to E$ such that the mapping $I_X-\Phi$ is compact and uniformly finitely approximable (where $X\subset E$ and I_X is the injection of X into E) [the reviewer, Math. Ann. **141** (1960), 286–296; MR 24 #A1004; ibid. **145** (1961/62), 464–465; MR 25 #1437]; the second condition is redundant if E is admissible. Thus there is considerable interest in deciding whether every space E is admissible, and in determining the admissibility of various spaces E which are not locally convex. This was accomplished earlier by the author for the spaces $L^p[0,1]$ $(0<p<1)$ [see #3873 above]; here he treats the space $S[0,1]$ of all measurable functions on the unit interval, topologized by means of convergence in measure ($d(f,g)=\int_0^1[|f(t)-g(t)|/(1+|f(t)-g(t)|)]\,dt$).

For integers $1\leq k\leq n$, let $I(k,n)$ denote the interval $[(k-1)/n,k/n]$ and $\chi_{k,n}$ the characteristic function of $I(k,n)$. Let F_n denote the linear hull of the set $\{\chi_{1,n},\chi_{2,n},\cdots,\chi_{n,n}\}$. For non-negative $f\in S[0,1]$, let

$$s_{k,n}(f)=\left(\int_{I(k,n)}[f(t)/(1+f(t))]\,dt\right)\Big/\left(\int_{I(k,n)}[1/(1+f(t))]\,dt\right)$$

and let $s_n(f)=\sum_{k=1}^n s_{k,n}(f)\chi_{k,n}\in F_n$. Finally, for arbitrary $f\in S[0,1]$ let $s_n(f)=s_n(f^+)-s_n(f^-)$. The author shows that $S[0,1]$ is admissible by proving that s_n is a retraction of $S[0,1]$ onto F_n, that the sequence $s_1,s_2,\cdots$ is equicontinuous, and that for each f the sequence $s_1(f)$, $s_2(f),\cdots$ converges to f. *Victor Klee* (Seattle, Wash.)

Robert, Jacques 3875

Continuité d'un opérateur non linéaire sur certains espaces de suites.

C. R. Acad. Sci. Paris **259** (1964), 1287–1290.

Let l be an F-space (in the sense of Banach) of sequences $X=\{x_n\}$ with an F-norm $|X|$. Let us write $E_n=\delta_n{}^i$, where $\delta_n{}^i=0$ for $n\neq i$ and $\delta_i{}^i=1$. The author calls the space "F-monotone" if the following conditions are satisfied. (A_1) all finite sequences belong to l; (A_2) $|X-x_nE_n|\leq|X|$

for all $X \in l$; (A_3) for every n, $|aE_n|$ is a nondecreasing function of $|a|$. Now, a map Φ of a space l into a space m by means of a sequence $\{f_n\}$ of real functions of a real variable is defined by the formula $\Phi\{x_n\} = \{f_n(x_n)\}$. Assuming the functions $f_n(u)$ to be continuous at $u = x_n$, the author gives a necessary and sufficient condition for the continuity of Φ (Theorem 3). This theorem is applied to maps Φ of l^1 into l^1 and to maps of an Orlicz space of sequences l_{M_1} into another Orlicz space of sequences l_{M_2}. As an example, we quote Theorem 5.b. Let l_{M_1} and l_{M_2} be two Orlicz spaces of sequences defined by the functions $M_1(u)$ and $M_2(u)$, respectively. Let the functions $f_n(u)$ be continuous and equal to zero at $X = 0$. Then the map Φ of l_{M_1} into l_{M_2} is continuous at $X = 0$ if and only if for every $\alpha > 0$ there exist positive constants β, ε and b and a sequence $\{a_n\} \in l^1$ such that $M_2(\alpha|f_n(u)|) \le a_n + bM_1(\beta|u|)$ for all indices n and all $|u| \le \varepsilon$. *J. ★Espaces vectoriels pseudotopologiques et théorie des distributions.
Hochschulbücher für Mathematik, Band 59.
VEB Deutscher Verlag der Wissenschaften, Berlin, 1963. viii + 232 *pp.* *DM* 35.00.

This is an attractive introduction to the theory of distributions and relevant parts of functional analysis. In the past there have been two divergent approaches to the subject. Schwartz's approach is by means of the general theory of locally convex spaces developed by Bourbaki, while the formulations of Gel'fand and Šilov, Mikusiński, König, Sikorski, Korevaar, Sebastião e Silva, Urbanik and others are based on simpler topological tools and rely on convergence of sequences whenever possible. Schwartz's approach has the advantage of generality and elegance, while the others are more intuitive, more readily accepted by physicists, and better adapted to certain applications. The present author draws from both approaches in order to obtain a large share of the advantages of each. This is done efficiently and with good taste, so that his contribution is considerably more than a mere amalgamation of what has been done before. His main departure from the general theory of locally convex spaces lies in the fact if E is the space of all continuous linear transformations of one locally convex space into another, or is any of several other important linear spaces whose structure cannot be described by means of a metrizable locally convex topology, then he regards E as a pseudotopological union of locally convex spaces (in the sense described below) and employs true topologies only in an auxiliary fashion. In this respect, he follows the ideas of Gel'fand and Šilov, but he is able to go beyond their treatment by providing a satisfactory theory of vector-valued distributions.

Chapter 1 (58 pages) starts at an elementary level and proceeds to the key notions of a polynormed space and a pseudotopological union of topological linear spaces. (Both of these notions have been studied previously by the author. The second notion has been used in distribution theory by Schwartz and especially by Gel'fand and Šilov. Polynormed spaces have been studied by Mikusiński as "réunions d'espaces de Banach" and by Sebastião e Silva and Waelbroeck as "espaces à bornés".) Suppose that $\{E_\lambda\}_{\lambda \in L}$ is a family of linear subspaces of a linear space E, and that each space E_λ is equipped with a topology. Then E is said to be the "pseudotopological union" of the spaces E_λ provided $E = \bigcup_{\lambda \in L} E_\lambda$, and whenever $\lambda', \lambda'' \in L$ there exists $\lambda \in L$ such that $E_{\lambda'} \cup E_{\lambda''} \subset E_\lambda$ and the given topologies of the spaces $E_{\lambda'}$ and $E_{\lambda''}$ are finer than those induced by the topology of E_λ. Notions such as the limit of a net (generalized sequence), continuity of a function, etc., are introduced in terms of the pseudotopological structure of E by referring directly to the spaces E_λ and without introducing a genuine topology in the space E itself. The pseudotopological union $E = \bigcup_{\lambda \in L} E_\lambda$ is said to be "polynormed" if each E_λ is a normed space. The structure of a polynormed space E can always be described by a family $\{\|\ \|_\alpha\}_{\alpha \in A}$ of generalized norms (functions satisfying the usual requirements for a norm except that they may assume the value $+\infty$) such that for each $x \in E$ there exists $\alpha \in A$ with $\|x\|_\alpha < \infty$, and whenever $\alpha', \alpha'' \in A$, there exists $\alpha \in A$ such that

$$\|\ \|_\alpha \le \inf(\|\ \|_{\alpha'}, \|\ \|_{\alpha''}).$$

Let $D_{[-r,r]^n}$ denote the space of all infinitely differentiable functions x on R^n such that x and all of its derivatives vanish everywhere on the complement of the cube $[-r,r]^n \subset R^n$. This is a locally convex space, denumerably normed by an increasing sequence of norms corresponding to the partial derivatives of various orders. The pseudotopological union of the family $\{D_{[-r,r]^n}\}_{r>0}$ is the space D_{R^n} of all infinitely differentiable functions with compact support on R^n. Let Z_r^n denote the set of all analytic entire functions on C^n (where C is the complex plane) such that for each n-tuple $q=(q_1,\cdots,q_n)$ of non-negative integers there exists a constant M_q such that $|s_1^{q_1}\cdots s_n^{q_n}z(s)| \leq M_q e^{r|\mathrm{Im}\, s|}$ for all $s=(s_1,\cdots,s_n)\in C^n$ (where $|\mathrm{Im}\, s| = (\sum_{i=1}^n (\mathrm{Im}\, s_i)^2)^{1/2}$). Each space Z_r^n is (in a natural way) a denumerably normed locally convex space, and the pseudotopological union Z^n of the family $\{Z_r^n\}_{r>0}$ is a space which was introduced by Gel'fand and Šilov. Chapter 1 culminates with a description of the Fourier transform and a proof that it determines an isomorphism between the spaces D_{R^n} and Z^n, both algebraically and for their structures as pseudotopological unions of locally convex spaces.

Chapter 2 (38 pages) is concerned with the space of all continuous linear transformations of a space E into a space F. Starting with the standard case of normed spaces, the author proceeds to the case in which E and F are both locally convex spaces and finally to the case in which both are pseudotopological unions of locally convex spaces. Standard results on the existence and extension of continuous linear forms are proved and are then extended to the more general situations required in the author's theory. A key result asserts that if a linear space E is the union of an increasing sequence $E_1 \subset E_2 \subset \cdots$ of bornological spaces such that E_n is always a closed subspace of E_{n+1}, then E admits a bornological topology such that each E_n is a closed subspace of E, every bounded subset of E is a bounded subset of some E_n, and a linear transformation of E into an arbitrary locally convex space is continuous if and only if its restriction to E_n is always continuous. Dual spaces are defined and the dual of a locally convex space is represented as a polynormed space in a natural way. A distribution is defined as a continuous linear form on the space D_{R^n}. Derivatives and primitives of distributions are defined, as well as the convolution of two distributions, and the basic properties of these notions are established.

Chapter 3 (42 pages) is devoted to tensor products. Nuclear operations and spaces are defined, and the nuclearity of the spaces $D_{[-r,r]^n}$ is established. The chapter culminates with Schwartz's "théorème de noyaux", asserting that the space of all weakly continuous linear transformations of D_{R^n} into $D^*_{R^n}$ is isomorphic to the space D^{*n+m}. This is proved in the manner of Ehrenpreis [Proc. Amer. Math. Soc. 7 (1956), 713–718; MR 18, 584] and Gask [Math. Scand. 8 (1960), 327–332; MR 23 #A2740].

Chapter 4 (57 pages) treats vector-valued functions, measures, integrals and distributions. The differential calculus of vector-valued functions is based on the author's notion of Fréchet differential [Marinescu, Bull. Math. Soc. Sci. Math. Phys. R. P. Roumaine (N.S.) 1 (49) (1957), 77–86; MR 20 #1188], which is intimately related to the pseudotopological structure of the space of linear transformations. The approach to vector-valued measures and integrals is due jointly to the author and to Dinculeanu, and appeared first in the author's earlier book [*Topological and pseudo-topological vector spaces* (Romanian), Editura Acad. R. P. Romîne, Bucharest, 1959; MR 21 #6525]. It is much closer to the approach of Bochner than to that of Bourbaki. The treatment of vector-valued distributions is less general than that of Schwartz [Ann. Inst. Fourier (Grenoble) 7 (1957), 1–141; MR 21 #6534; ibid. 8 (1958), 1–209; MR 22 #8322], but is deemed to be adequate for most applications. It draws on the paper of Sebastião e Silva [Portugal. Math. 19 (1960), 1–80; errata, ibid. 19 (1960), 243–244; MR 25 #453].

Chapter 5 (16 pages) is concerned with applications, its sections having the following titles: (1) Représentations intégrales de certaines opérations linéaires; (2) Décompositions intégrales des espaces nucléaires suivant les opérateurs propres d'un opérateur symétrique; (3) Équations différentielles et aux dérivées partielles; (4) Processus stochastiques generalisés. (The last two areas are only touched upon.)

There are useful bibliographical notes at the end of each chapter, and a bibliography of about 300 items. However, most of these items are not mentioned in the text and many of them are related to the subject of the book only in that they are somehow concerned with topological linear spaces. In the reviewer's opinion, the bibliography would be much more useful if it were more selective and if the author had added a few more pages as a guide to those items which are not mentioned elsewhere in the text. Curiously, the bibliography includes three papers by "Gelfand und Schilow" and three others by "Ghelfand et Šilov".

Inevitably, there are a few minor ambiguities, slips or misprints in the text, but none of those noted by the reviewer should cause any serious difficulty. The book is well written and attractively printed. It appears to be suitable both for a formal course on distribution theory (prerequisite: a course in real analysis) and for individual study. *Victor Klee* (Seattle, Wash.)

Semjanistyi, V. I. 3879

Some integral transformations and integral geometry in an elliptic space. (Russian)

Trudy Sem. Vektor. Tenzor. Anal. **12** (1963), 397–441.

Proofs are given for the elliptic case of theorems announced by the author [Dokl. Akad. Nauk SSSR **136** (1961), 288–291; MR **24** #A2842]. Explicit formulas for the inversion of Radon-type transforms in the space of generalized functions on projective n-space are obtained by examining their extensions to Euclidean space as even generalized functions, homogeneous of arbitrary (complex) order. For n odd, some of the formulas were first found by Helgason [see Section 4 of the paper reviewed below #4068]. *L. W. Green* (Minneapolis, Minn.)

Ding, Guang-gui [Ting, Kuang-kuei] 3880

The resonance theorem for a noncomplete space.

Acta Math. Sinica **13** (1963), 216–222 (*Chinese*); *translated as Chinese Math.* 4 (1963), 235–241.

Let $\{T_\lambda\}$ be a family of bounded linear transformations of a normed space E into (perhaps different) normed spaces F_λ, and let $M(x)=\sup_\lambda \|T_\lambda(x)\|$, $x\in E$. It is well known that if E is complete, then $M(x)<\infty$ everywhere implies M is bounded, and that the result fails in general if E is

incomplete. In this note it is shown that $M < \infty$ everywhere and M upper semicontinuous (at one point) imply M is bounded, whether E is complete or not. The proofs are elementary and are couched in the terminology of convex functionals. *A. Brown* (Ann Arbor, Mich.)

Hildebrandt, Stefan; Wienholtz, Ernst 3881
Constructive proofs of representation theorems in separable Hilbert space.
Comm. Pure Appl. Math. **17** (1964), 369–373.

Let $\{e_1, e_2, e_3, \cdots\}$ be a linearly independent sequence of vectors that span a Hilbert space H and let H_n be the span of $\{e_1, \cdots, e_n\}$, $n = 1, 2, 3, \cdots$. If B is a bounded bilinear form and L is a bounded linear form on H, and if there exists a uniformly bounded sequence Q_n of operators on H_n such that $|B(Q_n x, x)| \geq \alpha\|x\|^2$ (for some positive α, all x, and all sufficiently large n), then there exists a unique y in H such that $B(x, y) = L(x)$ for all x; the vector y is, in fact, the limit of the sequence whose nth term is $\sum_{k=1}^n \beta_{kn} e_k$, where the β's are the solutions of the equations $\sum_{k=1}^n \beta_{kn} B(e_i, e_k) = L(e_i)$, $i = 1, \cdots, n$. The authors call this a "constructive" version of that corollary of the Riesz representation theorem which is known to students of partial differential equations as the Lax-Milgram lemma. They derive some elementary consequences and special cases. *P. R. Halmos* (Ann Arbor, Mich.)

Hildebrandt, Stefan 3882
The closure of the numerical range of an operator as spectral set.
Comm. Pure Appl. Math. **17** (1964), 415–421.

If T is a linear transformation on a Hilbert space with numerical range W $(= \{(Tx, x) : \|x\| = 1\})$ and if $\bar{W}$ is a spectral set of T (that is, $\|f(T)\| \leq \sup\{|f(\lambda)| : \lambda \in \bar{W}\}$ for all rational functions f with no poles in $\bar{W}$), then (i) $\sup\{|(Tx, x)| : \|x\| = 1\} = \|T\|$; (ii) the set E of all extreme points of $\bar{W}$ is included in the approximate point spectrum of T, and $E \cap W$ is the same as the set of all proper values of T in E; (iii) $\bar{W}$ is the convex hull of the spectrum of T; and (iv) a necessary and sufficient condition that W be closed is that E be included in the point spectrum of T.

The paper consists of this main theorem together with a few examples, corollaries, and related remarks.
P. R. Halmos (Ann Arbor, Mich.)

Kardžiev, N. 3883
Calculation of the eigenvalues of a self-adjoint operator. (Russian. German summary)
C. R. Acad. Bulgare Sci. **16** (1963), 793–796.

The paper exploits a variation of the Galerkin method to obtain upper and lower bounds for the eigenvalues of a self-adjoint completely continuous operator in Hilbert space. The orthogonalization is not with respect to the coordinate elements z_i but with respect to elements which are linear transforms of the z_i. *H. J. Stetter* (Munich)

Hopf, Eberhard 3884
Remarks on my paper "An inequality for positive linear integral operators".
J. Math. Mech. **12** (1963), 889–892.

The author considers linear integral operators

$$Kf(x) = \int_Y K(x, y) f(y) \mu(dy),$$

$x \in X, y \in Y$, in which μ is a given σ-finite measure defined in a σ-field of subsets of Y. The kernel is supposed to be essentially positive, that is, $\varphi \geq 0$, $\varphi \not\equiv 0$ imply $K\varphi > 0$. Under the additional hypothesis that the kernel has bounded cross-ratio, that is, that there exists a finite constant $k \geq 1$ such that

$$\frac{K\varphi(x)}{K\varphi(x')} \bigg/ \frac{K\psi(x)}{K\psi(x')} \leq k^2$$

holds for all functions $\varphi \geq 0$, $\psi \geq 0$, both $\not\equiv 0$, and for all points $x \in X$, $x' \in X$, the author [same J. **12** (1963), 683–692; MR **29** #2614] established a certain inequality involving the oscillations of f/p and of Kf/Kp for such an operator K.

The second part of the earlier paper dealt with applications of the inequality. The first of these consisted in a simple rederivation of classical results of Frobenius-Perron (matrices) and Jentzsch (integral operators) about the proper values of $Kf = \lambda f$. The second application was the proof of a new inequality about the proper values λ different from the absolutely largest one $\lambda_0 > 0$. The author re-examines in the present paper the hypotheses about K under which those applications are valid and substantially reduces the somewhat too restrictive hypothesis made in the earlier paper. It is again supposed that $Y = X$ and that the kernel is μ-measurable in x for fixed y. This insures that a μ-measurable function $f(x)$ over X goes over again into a μ-measurable function $Kf(x)$ if $Kf(x)$ is well-defined for every $x \in X$.

Lučka, A. Ju.; Kurpel', N. S. 3885
On a non-stationary iteration method for the approximate solution of linear operator equations. (Russian)
Ukrain. Mat. Ž. **16** (1964), 389–395.

Let A be a bounded linear operator in a Banach space E and let $f \in E$. It is desired to solve the linear equation (*) $u = f + Au$ by using a sequence (A_n) of operators in E such that $(I - A_n)^{-1}$ exists. Let $L_n = (I - A_n)^{-1}(A - A_n)$ and let u_0 be arbitrary. Suppose that

$$\lim_{n \to \infty} \|L_n L_{n-1} \cdots L_2 L_1\| = 0,$$

and consider the iteration $u_n = (I - A_n)^{-1} f + L_n u_{n-1}$, $n \geq 1$. It is asserted (but not proved) that this iteration procedure converges to the unique solution u^* of (*). Moreover, if $\|L_n\| < 1$, then

$$\|u^* - u_n\| < \|L_n\|(1 - \|L_n\|)^{-1}\|u_n - u_{n-1}\|.$$

Modifications of this procedure are considered where the A_n are projections of A into subspaces of E.

Putnam, C. R. 3886
On the structure of semi-normal operators.
Bull. Amer. Math. Soc. **69** (1963), 818–819.

A bounded operator T in a Hilbert space $\mathfrak{H}$ is said to be semi-normal if $D = TT^* - T^*T \geq 0$ or ≤ 0. In this paper, some previous results of the author concerning commutators [Amer. J. Math. **86** (1964), 310–316; MR **29** #1552]

are applied to the study of semi-normal operators. It is immediately shown, for instance, that Re T and Im T are absolutely continuous on the smallest closed subspace of $\mathfrak{H}$ reducing T and containing the range of D. An estimate of $\|D\|$ by certain quantities related to the spectra of Re T and Im T is also given.

Marčuk, G. I. 3887

On the formulation of certain inverse problems. (Russian)

Dokl. Akad. Nauk SSSR **156** (1964), 503–506.

The author considers an equation in linear operator form, $L\varphi=f$, and its conjugate equation $L^*\varphi_p{}^*=p$ and the linear functional $J_p(\varphi)=(p,\varphi)=(f,\varphi_p{}^*)$. The problem is to determine L from $J_p(\varphi)$, given by physical indications. He states how to approximate the solution of the problem starting from a solution of

$$L_1\varphi_1 = f_1,$$
$$L^*\varphi_{1p}{}^* = p$$

which corresponds to the prognostic values of the parameters sought. A perturbation method is used.

The note is very interesting inasmuch as the problem is related to many problems of technology, as is indicated by the author.

P. K. Ghosh (Calcutta)

Rejto, P. A. 3888

On gentle perturbations. II.

Comm. Pure Appl. Math. **17** (1964), 257–292.

Part I appeared in same Comm. **16** (1963), 279–303 [MR **27** #4089]. If S and T are selfadjoint transformations in a Hilbert space such that $(S-w)^{-1}-(T-w)^{-1}$ is of trace class for some, and hence every, non-real number w, the absolutely continuous parts of S and T are known to be unitarily equivalent. It is now shown that the spectrum of T is absolutely continuous in an interval (a,b) if the spectrum of S is absolutely continuous in (a,b) and if the perturbation is "smooth". By using a canonical model of the perturbation situation (see, for example, the reviewer [Amer. J. Math. **84** (1962), 543–560; MR **27** #4083]), the author is able to assume that the undisturbed transformation S is multiplication by x in some L^2 space of vector-valued functions. In this preliminary paper he assumes that $T-S$ is bounded and has finite-dimensional range, but the method is quite general. Smoothness is interpreted as a condition on the kernel representing $T-S$, but since the canonical model is a unitary equivalent of the perturbation situation, the hypothesis will no doubt eventually be reformulated as a condition on resolvents. The paper is of interest for introducing local questions in perturbation theory and opening up a new area for research.

Ringrose, J. R. 3889

On the resolvent and the principal vectors of a compact linear operator.

Proc. Cambridge Philos. Soc. **60** (1964), 525–531.

This is a continuation of the author's previous paper [Proc. London Math. Soc. (3) **12** (1962), 367–384; MR **25** #458]. Let T be a compact linear operator in a complex Hilbert space $\mathfrak{H}$. In the preceding paper, generalizing the theorem of von Neumann and of Aronszajn and Smith [Ann. of Math. (2) **60** (1954), 345–350; MR **16**, 488], the author showed that there is a simple resolution $\{E_\lambda\}_{0\le\lambda\le1}$ of the identity in $\mathfrak{H}$ such that $E_\lambda TE_\lambda=TE_\lambda$. In the present paper, he gives constructions for the resolvent of T, and for a complete set of principal vectors, in terms of T, $\{E_\lambda\}$, and the diagonal coefficients (α_λ) of T. Moreover, those results are applied to Volterra integral operators.

Thyssen, M. 3890

Une condition d'isométrie pour un opérateur linéaire.

Bull. Soc. Roy. Sci. Liège **33** (1964), 141–142.

T. Nieminen raised the following question [Ann. Acad. Sci. Fenn. Ser. A I No. 316 (1962); MR **25** #2452]: If T is a bounded operator on a Hilbert space, the spectrum of which is a subset of $|z|=1$ and whose resolvent satisfies the inequality $\|R_z\|\le\big||z|-1\big|^{-1}$ on the resolvent set, does it follow that T is unitary?

In this paper the author makes an unsuccessful attempt at settling this question in the negative. This question, however, has been already settled in the affirmative by W. F. Donoghue [Inst. Hautes Études Sci. Publ. Math. No. 16 (1963), 31–33; MR **27** #2804], whose note is listed in the bibliography of the paper.

Analysis of a new formalism in perturbation theory.

Proc. Nat. Acad. Sci. U.S.A. **50** (1963), 598–601.

Given the equation $u=f+\lambda T(u)$, where f is a known function, λ is a parameter, and T is a linear transformation, find the unknown function u. The iterative technique of Bellman and Richardson [same Proc. **48** (1962), 1913–1915; MR **26** #416] (based on continued fraction expansion) is suggested and certain convergence proofs presented.

L. W. Ehrlich (Silver Spring, Md.)

Zabreĭko, P. P.; Krasnosel'skiĭ, M. A. 3893

Calculation of the index of a fixed point of a vector field. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 509–531.

Les auteurs exposent un algorithme à l'aide duquel on réduit le calcul de l'indice d'un point fixe, à l'étude d'un champ de vecteurs dans un espace à un nombre fini de dimensions. Les résultats s'obtiennent de quelques théorèmes dont voici les premiers. (1) Si (a) P est un opérateur linéaire de projection de l'espace E sur un sous-espace E_0 à un nombre fini de dimensions, $Q=I-P$, (b) A est un opérateur complètement continu, qui admet

la représentation $A = P + C_2 + C_3 + \cdots + C_m + D$ où C_i satisfont, entre autres restrictions, à la condition $C_i(\lambda x) = \lambda^i C_i(x)$ et $\|Dx\| \leq \beta(\rho)\|x\|^m$ ($\|x\| \leq \rho$), β étant une fonction non négative; (3) $PC_i = 0$ ($i = 2, 3, \cdots, k-1$) sur E et $PC_k \neq 0$, $QC_i P = 0$ ($i = 2, 3, \cdots, s$) sur E; (4) il existe un nombre naturel $r \leq m$, et un nombre $\rho_0 < 1$ tels que:

$$\|P(C_k x + C_{k+1} x + \cdots + C_r x)\| \geq \alpha\|x\|^r,$$

où $x \in E_m$, $\|x\| \leq \rho_0$, $\alpha > 0$, $r = s + k$, alors θ est un point fixe isolé du champ vectoriel complètement continu $\Phi = I - A$. Si γ_0 est l'indice du point fixe isolé θ de $P(C_k + C_{k+1} + \cdots + C_r)$, alors l'indice de θ pour Φ est γ_0. La théorie est appliquée à l'étude de l'équation des ondes symétriques sur les surfaces d'un fluide lourd.

Dixmier, Jacques 3895

Quasi-dual d'un idéal dans une C^*-algèbre.

Bull. Sci. Math. (2) **87** (1963), *1ière partie*, 7–11.

Let A denote a C^* algebra. The "dual object" $\hat{A}$ which consists of the unitary equivalence classes of irreducible representations appears to be of significance only for A of type I, and for this reason J. A. Ernest [Trans. Amer. Math. Soc. **104** (1962), 252–277; MR **25** #3383] has introduced the "quasi-dual" $A^\sim$ which consists of "primary classes" of representations. A representation in a "primary class" yields a "factor" M for its von Neumann algebra of operators, and while two different representations in the same class will have the same M when regarded as a C^* algebra, they may not be unitarily equivalent since the M' may be different. The concept of σ-ring and Borel set can be introduced into $A^\sim$ in a manner similar to the corresponding discussion for $\hat{A}$. Let J be a closed, two-sided ideal in A. A representation of A/J can be readily extended to a representation of A which is zero on J and thus $(A/J)^\sim$ can be mapped onto a subset E of $A^\sim$. It is shown that $A - E$ can be mapped on $J^\sim$ by simply restricting the domain of representations in $A - E$ to J. It is established that these mappings preserve type and normalcy, and that E and $A - E$ are Borel sets.

F. J. Murray (Durham, N.C.)

Lumer, G. 3896

Remarks on n-th roots of operators.

Acta Sci. Math. (*Szeged*) **25** (1964), 72–74.

This paper contains a quantitative refinement of the results of Halmos and Lumer [Proc. Amer. Math. Soc. **5** (1954), 589–595; MR **16**, 48] concerning operators on a Hilbert space that are invertible and lack a (square) root. Using the same method involving spectral multiplicity at points of the "compression spectrum" of the operator, it is proved that if H is a separable Hilbert space, there exist (1) an operator A of norm 1 such that every operator in the open sphere of radius 1 centred at A lacks a root of any order; (2) for every R, $0 < R < \frac{1}{2}\sqrt{2}$, an invertible operator A_R of norm 1 such that every operator in the open sphere of radius R centred at A_R lacks a root of any order; and (3) an invertible operator A_0 of norm 1 such that every operator in the open sphere of radius $(2\sqrt{2}+1)^{-1}$ centred at A_0 is invertible and lacks a root of any order. Several remarks are made concerning the analogous problem for commutative Banach algebras, for which the problem is much simpler. The question as to whether the set of invertible operators without roots of any order on a separable Hilbert space is open in the set of all invertible operators has almost surely a negative answer, illustrated by operators of the type described by Deckard and Pearcy [ibid. **14** (1963), 445–449; MR **26** #6774].

J. J. Schäffer (Pittsburgh, Pa.)

Schue, John R. 3897

The structure of hyperreducible triangular algebras.

Proc. Amer. Math. Soc. **15** (1964), 766–772.

The author proves a kind of Wedderburn theorem for triangular algebras in the sense of Kadison and Singer [Amer. J. Math. **82** (1960), 227–259; MR **22** #12409]: If $\mathcal{T}$ is a maximal hyperreducible triangular algebra acting on a separable Hilbert space with diagonal $\mathcal{A}$, where $\mathcal{A}$ is a maximally abelian self-adjoint subalgebra of a factor $\mathcal{B}$, then $\mathcal{T}$ is the algebraic sum of $\mathcal{A}$ and $\mathcal{S}$, where $\mathcal{S}$ is the weak closure of an increasing sequence of weakly closed nilpotent ideals. The author also proves that the sum $\mathcal{A} + \mathcal{S}$ is direct if (1) $\mathcal{B}$ is of type II, or (2) $\mathcal{B}$ is of type I and $\mathcal{A}$ is generated by an hermitian operator with pure point spectrum. It is interesting to note that the author's main technique is the analysis of the spectral manifolds introduced by Halmos [cf. *Introduction to Hilbert spaces and the theory of spectral multiplicity*, Chelsea, New York, 1951; MR **13**, 563], which is applied to the inner derivation $D_X Y = XY - YX$ considered as an operator acting on $\mathcal{A}$.

Stecenko, V. Ja. 3898

An estimate for the spectrum of some classes of linear operators. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1054–1057.

The purpose of this paper is to discuss bounds on positive operators A acting on a Banach space with a partial ordering induced by a normal cone [M. G. Kreĭn and M. A. Rutman, Uspehi Mat. Nauk **3** (1948), no. 1 (23), 3–95; MR **10**, 256; M. A. Krasnosel'skiĭ, *Positive solutions of operator equations* (Russian), Fizmatgiz, Moscow, 1962; MR **26** #2862] if the behavior of A on just one single element g in the interior K^0 of K is prescribed by an inequality $A^n g \leq \lambda_0 g$. An idea of Kreĭn's in the above-quoted paper is used and extended. It is asserted in Theorem 1 that, under the hypotheses just mentioned, the spectrum of A lies in the circle $|\lambda| \leq \sqrt[n]{\lambda_0}$. Theorem 2 is proved, asserting that the hypothesis that $g \in K^0$ can be weakened to obtain the same conclusion. Two other similar theorems are stated weakening the hypotheses on g and the operator A being positive, respectively.

G. K. Kalisch (Minneapolis, Minn.)

Ezajan, A. R.; Stecenko, V. Ja. 3899

Estimates of the spectrum of integral operators and infinite matrices. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 254–257.

The purpose of the note is to announce some estimates for the spectral radii of certain linear integral operators in the spaces C and L_p, $p>1$, and for certain infinite matrices. The main tool is a theorem asserting that if an operator B, in a real Banach space with a positive cone K which is normal and reproducing, is dominated by a positive linear operator A which is u_0-bounded above and such that $A^m u_0 \leq \lambda u_0$ for $u_0 \in K$, then the spectral radius of B is at most $\lambda^{1/m}$. Six estimates are given; we shall cite only one. Let Ω be a compact subset of R^n and let $K(t, s)$ $(t, s \in \Omega)$ be such that the operators B, A defined in $C(\Omega)$ by

$$Bx(t) = \int_\Omega K(t, s)x(s)\, ds, \qquad Ax(t) = \int_\Omega |K(t, s)|x(s)\, ds$$

are bounded. If $\lambda > 0$ is such that

$$\int_\Omega |K(t, s)|\left\{\lambda - \int_\Omega |K(s, r)|\, dr\right\} ds \geqq 0,$$

then it follows that the spectral radius of B is at most λ.

R. G. Bartle (Urbana, Ill.)

Greiner, Peter C. 3900

Eigenfunction expansions and scattering theory for perturbed elliptic partial differential operators.

Bull. Amer. Math. Soc. **70** (1964), 517–521.

The eigenfunction expansions are considered for partial differential operators of the form $H = P(D) + q(x)$ in R_n, where $P(D)$ is an elliptic polynomial of degree $2p > n/2$ in the n variables $D_j = i\partial/\partial x_j$ and $q(x) \in C_{2[n/2]}$, $q(x) = O(|x|^{-n-h})$ for some $h > 0$. H is self-adjoint (under suitable definition of $P(D)$) and has pure point spectrum in $(-\infty, 0)$. For the remaining part of the spectrum it is shown that, under certain additional assumptions on the kernel representing the resolvent $(H-z)^{-1}$, the part of H in the spectral interval (a, b) is unitarily equivalent to the part of $H_0 = P(D)$ in the same interval, the equivalence being given explicitly in terms of an integral involving the eigenfunctions $F(x, k)$ of H for "continuous eigenvalues" $P(k)$. These results are then applied to the special case $n = 2m+1$, $P(D) = (-\Delta)^p$, $4p > 2m+1$; it follows that the point spectrum of H in $(0, +\infty)$ is a closed, denumerable, nowhere dense set, and the unitary equivalence stated above holds true for any (a, b) containing no point spectrum.

T. Kato (Berkeley, Calif.)

Kasiev, A. 3901

A condition for the existence of an inverse operator for a differential operator in the space of generalized functions. (Russian. Uzbek summary)

Izv. Akad. Nauk UzSSR Ser. Fiz.-Mat. Nauk **1964**, *no.* 2, 23–30.

The paper is concerned with the partial differential equation

$$L\left(\frac{\partial}{\partial x_1}, \cdots, \frac{\partial}{\partial x_n}\right)U = T,$$

where $L(\partial/\partial x_1, \cdots, \partial/\partial x_n)$ is a homogeneous elliptic differential operator of order $2m$ $(2m < n)$ with constant coefficients and T is a distribution. A necessary and sufficient condition on T is given for the existence of a unique solution U in a class of distributions vanishing at infinity together with some of their derivatives. A sufficient condition was given by the author in a previous paper [same Izv. **1962**, no. 6, 27–31; MR **27** #5031].

Carroll, Robert 3902

Problems in linked operators. I.

Math. Ann. **151** (1963), 272–282.

This is the first of a series of papers, announced by the author, on the subject of what he calls linked operators. The aim is to get general results on abstract initial-value problems and, particularly, on uniqueness of the solutions. In such problems, one usually deals with differential operators $S = D_t + A$, where $D_t = d/dt$ and A is some linear operator on a space of functions or distributions in the "space variables", e.g., on the space L^2 of an open subset of R^n, Ω. When A is independent of t, S can be written $D_t \otimes I + I \otimes A$, and viewed as operating (at first) on subsets of $L_t^2 \otimes L_x^2(\Omega)$. One seeks a solution in suitable subspaces of the space of L^2 functions of t with values in the Hilbert space $L_x^2(\Omega)$; of course, this is simply $L^2_{t,x}(R_+^1 \times \Omega)$. But it can also be interpreted as the completion of the above tensor product for the $L^2_{t,x}$ norm. Thus it is natural to raise a more general question. Let E, H be two Hilbert spaces, $E \hat{\otimes}_\alpha H$ the completion of $E \otimes H$ for some "cross-norm" α, L, A two linear operators respectively defined in dense subspaces of E, H and with values in E, H. When are there extensions $\hat{S}$ of $S = L \otimes I + I \otimes A$ in $E \hat{\otimes}_\alpha H$ with the following three properties: $\hat{S}$ is 1-1; $\hat{S}$ is onto; $\hat{S}^{-1}$ is continuous? In the paper, sufficient conditions for the existence of such extensions are proved; the adjoint S^* is studied; simple examples are given.

Kesel'man, G. M. 3903

On the unconditional convergence of eigenfunction expansions of certain differential operators. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, *no.* 2 (39), 82–93.

The author studies a regular boundary-value problem H [see M. A. Naimark, *Linear differential operators* (Russian), GITTL, Moscow, 1954; MR **16**, 702]. Main result: Under certain conditions the eigenfunctions of H form an absolute basis in $L_2(0, 1)$. Recall that a basis $\{e_n\}$ is absolute if $\{e_{\alpha_n}\}$ is also a basis for each one-to-one map of the indices. In the case under consideration a basis is absolute if and only if it is a Riesz basis [N. K. Bari, Moskov. Gos. Univ. Učen. Zap. **148** (1951), Mat. **4**, 69–107; MR 14, 289; I. M. Gel'fand, ibid. **148** (1951), Mat. **4**, 224–225; MR 14, 289].

An analogous result was obtained independently by V. P. Mihaĭlov [Dokl. Akad. Nauk SSSR **144** (1962), 981–984; MR **26** #6824].

Kovtun, I. I. 3904

On the solution of an operator differential equation. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1963**, 322–324.

The author presents a method for the solution of the equation

$$\frac{dx}{dt} = [A + \varepsilon F(t)]x \tag{1}$$

in a Hilbert space H with a given initial condition $x(0)$, where x is a vector, A is a bounded operator in H, and $F(t)$ is some operator in H depending on the parameter t, which is the sum of a convergent series of operators. The method consists of a combination of projection and asymptotic methods. Thus, if $\{H_n\}$ denotes a sequence of finite-dimensional subspaces of H and P_n is a projection operator of H onto H_n, then, together with (1), the author considers the approximate equation

$$\frac{dx_n}{dt} = [A_n + \varepsilon F(t)]x_n, \tag{2}$$

where x_n is in H_n and $A_n = P_n A$ is the operator constructed by some projection method which has the property that $\|A_n - A\| \to 0$ as $n \to \infty$. Using the asymptotic method the author obtains a formal solution x_n^* of (2) and then establishes the asymptotic estimate for the error $\|x - x_n^*\|$, where x is the solution of (1).

W. V. Petryshyn (Chicago, Ill.)

Lions, Jacques-Louis; Strauss, Walter A. 3905

Sur certains problèmes hyperboliques non linéaires.

C. R. Acad. Sci. Paris **257** (1963), 3267–3270.

Gli autori risolvono il problema misto (con condizioni nulle iniziali e nulla frontiera) per l'equazione non lineare $-\Delta u + u'' + \beta(u') = f$, dove Δ indica l'operatore di Laplace, $u' = \partial u/\partial t$, $u'' = \partial^2 u/\partial t^2$ ed è $\beta(u') = |u'|^{\rho-1}u'$ $(\rho > 1)$.

Precisamente, si dimostra che se $f \in L^2(0, T; L^2(\Omega))$ (qui Ω è un qualunque aperto di R^n) esiste una ed una sola soluzione (generalizzata) $u(t)$ tale che

$$u(0) = u'(0) = 0, \qquad u \in L^2(0, T; H_0^1(\Omega)),$$

$$u' \in L^\infty(0, T; L^2(\Omega)) \cap L^{\rho+1}(0, T; L^{\rho+1}(\Omega)).$$

Il procedimento è quello di Galerkin; si costruisce una successione approssimante u_n tale che u_n' sia debolmente convergente in $L^{\rho+1}(0, T; L^{\rho+1}(\Omega))$ verso u' e che $\beta(u_n')$ sia debolmente convergente in $L^{\rho+1/\rho}(0, T; L^{\rho+1/\rho}(\Omega))$ verso g; si dimostra che $g = \beta(u')$, seguendo un'idea di G. Minty.

Vengono poi dati risultati di regolarizzazione, in dipendenza da ulteriori proprietà di regolarità di f.

Ljance, V. È. 3906

Extension of the Fourier L-transform to locally square integrable functions. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 1026–1029.

If L is the operator in $L^2(0, \infty)$ generated by the differential operator $ly = -y'' + p(x)y$ with boundary conditions $y'(0) - \theta y(0) = 0$, where p and θ are such that L is not selfadjoint but has a finite set of spectral singularities, then the Fourier L-transform of $f \in L^2(0, \infty)$ is defined by the function $\omega(f, \lambda) = \int f(x)\omega(x, \lambda)\,dx$, where $\omega(x, \lambda)$ are solutions of $ly = \lambda y$ such that $\omega(0, \lambda) = 1$, $\omega_x'(0, \lambda) = \theta$, and its derivatives at spectral singularities of L. An extension of this definition for functions of exponential growth was given in the author's article [same Dokl. **152** (1963), 816–819; MR **28** #2276]. An extension to all functions locally square summable and valid for a wider class of p is given here, based on a Parseval equation for the L-transform defined above, and questions of its non-uniqueness and inversion are studied. Applications to partial differential equations are anticipated.

Matsuura, Shigetake 3907

Factorization of differential operators and decomposition of solutions of homogeneous equations.

Osaka Math. J. **15** (1963), 213–231.

Let Ω be an open set in n-dimensional Euclidean space. Let $L(X)$ be a polynomial in n variables $X = (X_1, \cdots, X_n)$. Suppose $D = (D_1, \cdots, D_n)$, where $D_k = (1/i)\partial/\partial x_k$. Problem: If $L(X) = P(X)Q(X)$, where P and Q are polynomials, when can a solution u of $L(D)u = 0$ in Ω be expressed in the form $u = u_1 + u_2$, where $P(D)u_1 = 0$ and $Q(D)u_2 = 0$ in Ω. When $\Omega = R^n$, V. P. Palamodov [Dokl. Akad. Nauk SSSR **142** (1962), 1278–1281; MR **26** #1598] solved the problem for various kinds of spaces of ordinary and generalized functions by giving an explicit form of a general solution of $L(D)u = 0$. In the present article the same problem is solved for various regions Ω and for various spaces of solutions, to wit, spaces of distributions which are stable under the operations of partial differentiations, spaces of C^∞ functions, spaces of polynomials, and spaces of complex-valued functions whose real and imaginary parts are analytic.

R. C. Gilbert (Fullerton, Calif.)

Mikolás, Miklós 3908

Sur la propriété principale des opérateurs différentiels généralisés.

C. R. Acad. Sci. Paris **258** (1964), 5315–5317.

Define ${}_aD^\mu f = {}_aD^\mu f|x = \lim_{n\to\infty}((x-a)/n)^{-\mu}{}_a\Delta_n^\mu f$, where ${}_a\Delta_n^\mu f = {}_a\Delta_n^\mu f|x = \sum_{p=0}^{n-1}(-1)^p\binom{\mu}{p} f(x - p(x-a)/n)$. Then ${}_aD^\nu f = f^{(\nu)}(x)$ $(\nu = 0, 1, 2, \cdots)$ if the right-hand term exists, and, for $\mu < 0$, ${}_aD^\mu f = {}_aI^{-\mu}f = \Gamma(-\mu)^{-1} \times \int_a^x f(t)(x-t)^{-\mu-1}\,dt$. Thus ${}_aD^\mu f$ is an "integro-derivative" operator. Assume the existence of either one of ${}_aD^{\mu_1}({}_aD^{\mu_2}f)$ or ${}_aD^{\mu_1+\mu_2}f$. Then it is proved that ${}_aD^{\mu_1}({}_aD^{\mu_2}f) = {}_aD^{\mu_1+\mu_2}f$ if and only if $\lim(n^{\mu_1}\cdot{}_a\Delta_n^{\mu_1}\eta_N|x) = 0$, where $\eta_m(t) = ((t-a)/m)^{-\mu_2}{}_a\Delta_m^{\mu_2}f|t - {}_aD^{\mu_2}f|t$ $(m = 1, 2, \cdots)$ and $N = N(t, x) = [n(t-a)/(x-a)]$.

K. Yosida (Tokyo)

Tanabe, Hiroki 3909

Evolution equations. (Japanese)

Sûgaku **14** (1962/63), 137–152.

This is an expository paper on evolution equations: $du/dt = A(t)u + f(t)$, where $A(t)$ is a closed and additive operator which is defined on a subspace of a Banach space X and whose values are in X, $f(t) \in X$, and $0 \leq t \leq T$. The quantity u is an unknown function of t whose values are in X. The problem treated in this paper is the existence and uniqueness of the initial-value problem for this equation. The author classifies methods roughly into two kinds: one based on the theory of one-parameter semi-groups and the other based on the theory of representations

of linear functionals in Hilbert spaces by bilinear forms. This paper is mostly concerned with the methods based on the theory of one-parameter semigroups. The main part of the paper is devoted to the explanation of the results in the following two papers: T. Kato [Nagoya Math. J. **19** (1961), 93–125; MR **26** #631] and T. Kato and H. Tanabe [Osaka Math. J. **14** (1962), 107–133; MR **25** #4367]. The author also briefly mentions an existence and uniqueness theorem due to J. L. Lions [*Équations différentielles opérationnelles et problèmes aux limites*, p. 127, Springer, Berlin, 1961; MR **27** #3935].

Y. Sibuya (Minneapolis, Minn.)

Zaidman, Samuel 3910

Soluzioni quasi-periodiche per alcune equazioni differenziali in spazi hilbertiani.

Ricerche Mat. **13** (1964), 118–134.

Let V and H be two Hilbert spaces with $V \subset H$, the canonical injection being continuous. Assume also that V with the topology induced by H is dense in H. Let $A(\ ,\ )$ be a continuous, Hermitian-symmetric sesquilinear form on V such that for each $\beta > 0$ there exists an $\alpha > 0$ such that

$$a(u, u) + \beta(u)_H{}^2 \geqq \alpha(u)_V{}^2, \qquad v \in V.$$

Here $|\cdot|_H$, $|\cdot|_V$ are the norms in V and H, respectively. Let A be the self-adjoint operator in H associated with the form a.

The author considers the differential equation $u''(t) - Au(t) = f(t)$, $-\infty < t < \infty$, and proves regularity theorems for weak solutions of this equation. In particular, he shows that if $f(t)$ is (Bochner) almost periodic in H and u is a bounded (in H) solution of $u'' - Au = f$, then u is almost periodic in V and u' is almost periodic in H.

The convergence of the method of steepest descents for nonlinear equations with variational or quasi-variational operators.

J. Math. Mech. **13** (1964), 765–794.

Zur Lösung der nichtlinearen Operatorgleichung $G(x) = \Theta$ in einem Hilbertraum werden Verfahren der Gestalt $x_{n+1} = x_n - \alpha_n T_n G(x_n)$ betrachtet. Seien $G(x) = x + F(x)$, der Operator F vollstetig, stetig differenzierbar im Fréchetschen Sinne und die Ableitung F_x' symmetrisch, weiterhin G_x' gleichmäßig bezüglich x positiv definit, die Operatoren T_n gleichmäßig bezüglich n beschränkt und positiv definit und T_n und G_{x_n}' miteinander vertauschbar, so gibt es Zahlen α_n, festgelegt durch gewisse Ungleichungen, für welche die Elemente x_n gegen eine Lösung konvergieren. Die Konvergenzgeschwindigkeit ist linear. Beim Beweis wird ausgenutzt, daß G unter den Voraussetzungen nach einem Satz von Kerner der Gradient eines Funktionals ist. Es folgen Erweiterungen auf bestimmte Operatoren, welche sich nicht als Gradient eines Funktionals darstellen lassen, sowie Anwendungen der Theorie auf das Dirichletsche Problem bei quasilinearen Differentialgleichungen und auf nichtlineare Integralgleichungen vom Hammersteinschen Typ.

CALCULUS OF VARIATIONS

See also 3519, 3776, 4565, 4635, 4636.

Bellman, Richard 3913

On a variational problem of Miele.

Astronaut. Acta **9** (1963), 199–200.

The problem of Miele and Saaris [same Acta **9** (1963), 184–198; MR **28** #4746] referred to in the title of this paper is that of minimizing the integral

$$\int_0^T \left[\frac{\rho^6}{\rho^2+\dot\rho^2} + 2(\rho^2+\dot\rho^2)^{1/2}\right] d\theta$$

subject to the constraint $\int_0^T \rho^2\, d\theta = a$. The author now shows how the theory of inequalities, specifically Young's inequality, can be used in giving simple alternative derivations of the fundamental properties of the solutions of this problem. Thus, from the observation that, by Young's inequality, $\int_0^T u^3\, dt + 2\int_0^T v^{3/2}\, dt \geq 3\int_0^T uv\, dt$ for any non-negative functions u and v, it follows by a simple substitution that

$$\int_0^T \left[\frac{\rho^6}{\rho^2+\dot\rho^2} + 2(\rho^2+\dot\rho^2)^{1/2}\right] d\theta \geq 3\int_0^T \rho^2\, d\theta,$$

with equality if and only if $\rho^2 + \dot\rho^2 = \rho^4$.

Lebesgue, Henri 3915
En marge du calcul des variations.
Préface par L.-C. Young.
Enseignement Math. (2) **9** (1963), 209–326.

As indicated by its title, this is a collection of interesting remarks by Lebesgue on various aspects of variational theory. The titles of the chapters are as follows. I: Sur une question de minimum. II: Sur le problème des isopérimètres. III: Sur quelques questions de minimum relatives aux courbes orbiformes et sur leurs rapports avec le calcul des variations. IV: Sur la plus courte distance entre deux points d'une surface développable. V: La méthode classique du calcul des variations. VI: La méthode directe du calcul des variations. Chapters I, II, III and the major part of Chapter VI were previously published in various journals. Chapter V uses a simple two-parameter family of variations to derive the Euler equation, the existence of the second derivative on the minimizing curve wherever $f_{y'y'} \neq 0$, and the concavity of $f(x, y, y')$ as a function of y'. Chapter VI is largely concerned with existence proofs for the Dirichlet problem by variational methods, and with errors in a related 1877 memoir of Carl Neumann [*Untersuchungen über das logarithmische und Newton'sche Potential*, Leipzig, 1877].

Rund, Hanno 3919
Canonical formalism for parameter-invariant integrals in the calculus of variations whose Lagrange functions involve second order derivatives.
Ann. Mat. Pura Appl. (4) **64** (1964), 99–107.

Dans une publication précédente [mêmes Ann. (4) **55** (1961), 77–104; MR **25** #1469], l'auteur avait développé une théorie des intégrales, invariantes par changement de paramètre, dont le lagrangien contient des dérivées d'ordre supérieur; cette théorie s'était révélée insuffisante pour les applications, parce que l'hamiltonien ne dépendait pas explicitement des dérivées premières des coordonnées de position. On définit ici un nouvel hamiltonien qui donne lieu à un formalisme moins compliqué que le précédent et plus immédiatement applicable à des problèmes spéciaux. Se généralisent au cas présent: la notion de champ géodésique (de Carathéodory), l'équation de Hamilton-Jacobi, les parenthèses de Poisson. La méthode est illustrée par un exemple d'un caractère assez général.

M. Janet (Paris)

Vinti, Calogero 3920
L'integrale di Weierstrass e l'integrale del Calcolo delle Variazioni in forma parametrica.
Ist. Lombardo Accad. Sci. Lett. Rend. A **97** (1963), 101–114.

A definition for Weierstrass integrals of the calculus of variations previously given by the author is here adapted to integrals W_C relative to the integrand $\Phi(x, y; x', y', \theta')$, where θ is the slope of tangent to $C \equiv [x(t), y(t)]$, even when $x'(t)$, $y'(t)$ are of bounded variation. Invariance of W_C with respect to parametrizations is obtained, and when the length L_C of C is finite, a theorem of approximation expressed by

$$\lim_{h\to 0} \int_0^{L_C} \Phi\left[x(s), y(s), x'(s), y'(s), \frac{\theta(s+h)-\theta(s)}{h}\right] ds = W_C$$

(s = arc length) is proved. The Lebesgue integral I_C is $\leq W_C$, as expected, and if use is made of a result of S. Cinquini [Atti Accad. Naz. Lincei Rend. Cl. Fis. Mat. Natur. (8) **29** (1960), 515–520; MR **25** #472], equality holds if and only if x', y' are absolutely continuous. Extensions to integrands with higher derivatives are sketched.

On the projection of the regular polytope {5, 3, 3} into a regular triacontagon.
Canad. Math. Bull. **7** (1964), 385–398.

The polytope {5, 3, 3} is one of the six convex regular 4-dimensional polytopes, and in some ways is the most complicated, being bounded by 120 dodecahedra and therefore called a 120-cell. The author uses two distinct methods to show the possibility of its projection, onto a plane, to be bounded by a regular 30-gon such that its symmetry group will be that of the regular triacontagon, viz., D_{30}, the dihedral group of order 60. In the projection, the 600 vertices can be classified in 12 sets, each consisting of 30 or 60 vertices which lie on a circle concentric with the outer triacontagon. A beautiful picture of the projection has been drawn as published and acknowledged earlier by Coxeter [*Introduction to geometry*, p. 403, Wiley, New York, 1961; MR **23** #A1251] showing the four rings of 30 regular

pentagons of four different sizes with the smallest forming the outermost and the largest the innermost ring. To realize and visualize this projection, the properties of the triacontagonal projection of the reciprocal polytope {3, 3, 5}, called the 600-cell [Coxeter, *Regular polytopes*, Macmillan, New York, 1963; MR 27 #1856], have been used in both methods. *S. Projective geometry in the one-dimensional affine group.

Canad. J. Math. 16 (1964), 683–700.

The elements of the affine group G of one variable $x' = \xi x + \eta$ can be represented by the points in the (ξ, η)-plane for which $\xi \neq 0$. In a projective interpretation, this means that the elements of the group are mapped onto the points of a projective plane from which two lines, L_∞ and L_0 (here $\xi = 0$), have been lifted. This gives rise to two kinds of parallelism. Of importance are the points $U = L_0 \cap L_\infty$, $0 \in L_0$, a point I in the plane representing the unit of the group, and $\infty = 0L \cap L_\infty$. The lines through I, except IV, are the normalizers of elements of G, IV is the commutator subgroup. The 0-parallel lines are left cosets, the ∞-parallels right cosets of the groups represented by lines through I. A projectively invariant construction is given for product and inverse. This allows a very detailed study of the lattice generated by normalizers, commutators, and their cosets by translation of statements of projective geometry. Some examples are given, and the treatment of the affine group over an arbitrary field F is indicated. *H. W. Guggenheimer* (Minneapolis, Minn.)

Mammana, Carmelo 3930

Sulle corrispondenze cremoniane piane la cui jacobiana ha una sola componente irriducibile.

Matematiche (Catania) 18 (1963), 164–186.

Es sei n der Grad der Transformation, μ der Grad der Jacobischen Kurve. Für $\mu = 1$ erhält man die ganzen Cremona-Transformationen. Es ist $\mu^2 | n-1$ oder $3|\mu$ $9 \times \mu$, $9|n+1$. Für die Zahlen n und μ mit dieser Nebenbedingung gibt es Transformationen. Die F-Punkte sind alle Nachbarpunkte eines von ihnen. Sie folgen einander auf einem Zweig z. Ihre Vielfachheit ist durch μ teilbar.

Ist der Zweig z linear, so haben alle F-Punkte die Vielfachheit μ. Ihre Anzahl sei t. Folgende Fälle, und nur sie, sind möglich:

μ	n	t
1	2	3
2	5	6
3	8	7
6	17	8

Ist der Zweig z von zweiter Ordnung, so sind 8 Fälle möglich, von denen 5 durchgerechnet werden.

O.-H. Keller (Halle)

Mammana, Carmelo 3931

Gruppi di corrispondenze cremoniane di S_r definiti da proprietà delle jacobiane.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 27–34.

Sei H die Gruppe aller nichtausgearteten Homographien eines projektiven komplexen Raumes S_r der Dimension $r \geq 2$, G die Gruppe aller Cremona-Transformationen von S_r und $\{F\}$ eine Menge von irreduziblen Hyperflächen in S_r. Gewisse Untermengen von G, deren Elemente durch die Jacobi'sche Form der Cremona-Transformationen und ihrer Inversen in Bezug auf die Hyperflächen aus $\{F\}$ charakterisiert sind, werden als Untergruppen von G nachgewiesen. Dabei verwendet der Verfasser eine Arbeit von G. Dantoni [Ann. Mat. Pura Appl. (4) **29** (1949), 243–246; MR **11**, 738]. In G existieren stets Cremona-Transformationen T derart, daß die Jacobi'schen Formen von T und T^{-1} einen gegebenen irreduziblen Kegel des S_r als einzige irreduzible Komponente besitzen. Als Anwendung werden im Falle $r \geq 3$ bzw. $r \geq 2$ und unter zusätzlichen Voraussetzungen über $\{F\}$ weitere Untergruppen von G angegeben. Besonderes Interesse beansprucht der Fall, daß $\{F\}$ aus einer Hyperebene des S_r bzw. aus einer ebenen Kurve vom Geschlecht $p \geq 0$ besteht. Abschließend definiert der Verfasser den Begriff der Klasse von Erzeugenden von G und leitet ein Theorem ab, das den bekannten Unterschied in der Faktorenzerlegung von G in den Fällen $r=2$ und $r \geq 3$ beleuchtet.

R. Moufang (Frankfurt a.M.)

Benedicty, Mario 3932

On plurilinearities among projective spaces.

Rend. Sem. Mat. Univ. Padova **34** (1964), 110–134.

The author investigates graphic plurilinearities, which are simply pluricorrespondences among projective spaces which generalize the concept of collineations between two linear spaces. The plurilinearities among three projective lines are classified.

D. Pedoe (Lafayette, Ind.)

Freudenthal, Ernst; Heinrich, Werner 3933

★Neue Behandlung der Kurven zweiter Ordnung durch Invarianten.

Mathematische Arbeitshefte, 18.

Ernst Klett Verlag, Stuttgart, 1963. 84 pp. *DM* 3.00.

From the authors' preface: "Dieser Lehrgang arbeitet ausschliesslich mit den erstmalig in der Ebene gedeuteten Bewegungsinvarianten der Kurven zweiter Ordnung (K_2) und zieht daher die Koordinatentranslations- und Koordinatendrehungsformeln nicht mehr heran. Er benutzt keine projektiven Koordinaten, keine Matrizen und kaum die Vektorrechnung. Der Lehrgang ist mehrfach in der Sachsenwaldschule in Reinbek (Bezirk Hamburg) und der Johann Heinrich Voss-Schule in Eutin (Holstein) erprobt worden."

This book will be of no use to intending scientists looking for a quick introduction to important properties of conics, but it is a very effective introduction for a young mathematician to coordinate geometry. It underlines far more effectively than most texts the essential distinction between intrinsic properties of a geometrical configuration and the relationship of such a configuration to a particular choice of axes. It treats all the basic properties of conics and systems of conics.

The chapter headings are: (I) Die fokalerzeugten Kurven zweiter Ordnung; (II) Fokalerzeugte Kurven zweiter Ordnung in allgemeiner; (III) Klassifikation und nahere invariante Beschreibung der Kurven zweiter Ordnung; (IV) Mannigfaltigkeiten von Kurven zweiter Ordnung.

D. B. Scott (Brighton)

Ellers, Erich; Karzel, Helmut 3934

Endliche Inzidenzgruppen.

Abh. Math. Sem. Univ. Hamburg **27** (1964), 250–264.

Ein projektiver Raum einer Dimension >1 zusammen mit einer auf der Menge seiner Punkte erklärten Gruppenverknüpfung heißt Inzidenzgruppe, wenn die Linkstranslationen der Gruppe Kollineationen des Raumes sind. Als Gruppen betrachtet sind die Inzidenzgruppen (bis auf Isomorphie) gerade die (auf den Punkten) scharf einfach transitiven Gruppen von Kollineationen projektiver Räume (mit Dimension >1). Die desarguesschen Inzidenzgruppen lassen sich durch Paare (F, K) darstellen, wobei F ein Fastkörper und K ein Unterschiefkörper von F ist, dessen multiplikative Gruppe Normalteiler in der von F ist und über dem F einen Rang >2 hat. Mittels der Zassenhausschen Ergebnisse über die Struktur der Fastkörper werden so die sämtlichen endlichen desarguesschen Inzidenzgruppen angegeben und daraufhin untersucht, wenn die Linkstranslationen als Kollineationen sämtlich linear sind.

G. Pickert (Giessen)

Srinivasan, B. R. 3935

On the net of conics with a common self-polar triangle. II.

J. Madras Univ. B **32** (1962), 71–101.

In this second section of the author's Madras thesis of 1959 [for the first section see J. Madras Univ. Sect. B **31** (1961), 75–95; MR **27** #1864], Chapter IV deals with the one-to-one mapping of the conics S of the net $ax^2+by^2+cz^2=0$ on the point $S'(a,b,c)$ of the projective plane. Studied are the "F-curve" of two net conics S and S', i.e., the conic through the points of contact of the common tangents to S and S', the reciprocation of the conics of the net with respect to a net conic, considered as a quadratic involution, in-, out- and apolarity of conics (S is out-polar to S' if the polar conic of point S with respect to the fundamental triangle passes through S') and conics which are harmonically separated by two of the degenerate conics in their pencil. Chapter V brings in a metrical specialization, Chapter VI a dual representation, so that instead of point loci in the projective plane we have envelopes of lines.

Baldus, Richard 3936

★Nichteuklidische Geometrie. Hyperbolische Geometrie der Ebene.

Vierte Auflage. Bearbeitet und ergänzt von Frank Löbell. Sammlung Göschen, Bd. 970/970a.

Walter de Gruyter & Co., Berlin, 1964. 158 pp. *DM* 5.80.

There are very few changes compared with the pre-war editions. Trigonometry and analytic geometry have been expanded, and an appendix on Clifford-Klein surfaces has been added. It remains one of the outstanding books on non-euclidean geometry. (The careful treatment of area has been taken over unchanged from the second edition (1942).) *H. W. Guggenheimer* (Minneapolis, Minn.)

Marchionna, Ermanno 3937

Varietà di prima specie ed ipersuperficie di aggiunzione.
Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 105–125.

Soit dans un espace projectif S_r une variété algébrique définie dans le corps complexe pure, c'est-à-dire dont toutes les composantes irréductibles aient la même dimension d; elle est localement normale si à partir de l assez grand le système linéaire coupé par la totalité des formes d'ordre l est complet. L'auteur démontre que si l'on considère deux variétés V_d et V_d', V_d irréductible localement normale, V_d' pure sans parties multiples telles que V_d+V_d' soit de la première espèce au sens de Dubreil, que leur intersection D soit aussi pure sans parties multiples, si E est la section hyperplane générique de V_d, le système linéaire complet $|lE-D|$ qui existe effectivement est coupé sur V_d en dehors de D par la totalité des formes d'ordre l passant par V_d'; généralisation du Restsatz de Severi. Si l'on note $P(W_d, l)$ la postulation de W_d pour les formes d'ordre l, la relation $P(V_d, l)+P(V_d', l)=P(V_d+V_d', l)+P(D, l)$ exprime que V et V' sont "régulièrement enchainées". Si V_d et V_d' satisfont aux conditions du théorème, une condition suffisante pour qu'elles soient toutes deux de la première espèce est que D le soit. Si de plus une section hyperplane générale de $V+V'$ est de la première espèce, la condition est nécessaire. Sur une V_d irréductible, privée de variétés multiples de dimension $d-1$, de section hyperplane E, une variété $(d-1)$-dimensionnelle A pure sans parties multiples est hypersurface d'adjonction si les formes d'ordre quelconque l, passant par A, coupent sur V_d en dehors de A le système complet $|lE-A|$. Étude de quelques propriétés de ces hypersurfaces d'adjonction, une V_d localement normale qui contient une hypersurface A de la première espèce l'est aussi si, sur elle, A est d'adjonction. Lien avec de nombreuses propriétés des variétés arithmétiquement normales, conduisant à de nouveaux résultats sur les multiples de $|E|$ pour une variété irréductible. *B. d'Orgeval* (Dijon)

Etayo, José Javier 3938

Extension of the notion of linearity in algebraic geometry and a concept of algebraicity. (Spanish)

Permutti, Rodolfo 3939

Sulla varietà delle corde di una varietà algebrica irriducibile non singolare. (English summary)
Rend. Accad. Sci. Fis. Mat. Napoli (4) **30** (1963), 275–280.

Author's summary: "The author studies in which cases the manifold of chords of an algebraic irreducible non-singular manifold V_k of S_{2k+1}, meeting a general S_l, is reducible and gives a simple proof of a known theorem concerning the double manifold of the projection of a V_k of S_{2k+1} from an S_{k-1} into an S_{k+1}."

Godeaux, Lucien 3940

Construction de quelques surfaces projectivement canoniques. I.
Acad. Roy. Belg. Bull. Cl. Sci. (5) **50** (1964), 227–234.

Author's summary: "Construction, au moyen de la théorie des involutions, de quatre surfaces projectivement canoniques, c'est-à-dire dont le système canonique coïncide avec le système des sections hyperplanes."

Longo, C. 3941

Classificazione di trivettori o di complessi lineari di piani.
Univ. e Politec. Torino Rend. Sem. Mat. **22** (1962/63), 19–38 (1964).

Eingangs werden die p-Vektoren eines $(n+1)$-dimensionalen Vektorraumes E_{n+1} und der duale Begriff der p-Formen erklärt. Dem entsprechend folgt die Definition eines linearen Komplexes $L_n^{(p-1)}$ von projektiven Räumen S_{p-1} im projektiven Raum S_n der durch die (kontravarianten) Vektoren von E_{n+1} bestimmten Richtungen mittels einer linearen Gleichung in den Grassmannschen Koordinaten der S_{p-1}. Das Problem der Kennzeichnung der p-Vektoren besteht nun darin, die kleinste Zahl von unzerlegbaren (unabhängigen) p-Vektoren zu bestimmen, mittels derer ein gegebener p-Vektor als Linearkombination darstellbar ist. Eine entsprechende Formulierung dieser Aufgabe wird auf dem Begriff der linearen Komplexe $L_n^{(q)}$ basiert.

Zweck der Abhandlung ist, die verschiedenen (bekannten) Methoden zu untersuchen und vergleichen, die im Fall $p=3$ (Trivektoren) und für $n\leq 7$ und teilweise auch für $n=8$ zu dieser Klassifikation führen. *H. R. Müller* (Braunschweig)

Tazzi Cantalupi, Gabriella 3942

Alcuni teoremi esistenziali sui fasci reali massimali di curve algebriche.
Ist. Lombardo Accad. Sci. Lett. Rend. A **97** (1963), 763–772.

This is a contribution to the topology of curves and surfaces in algebraic geometry over the real number field, in particular, of a surface Σ on which is a pencil of curves Φ of genus p, without singular members, each Φ having the maximum number $p+1$ of disjoint circuits. The main result is that for every integer $m>0$, there exist such surfaces for $p=(m-1)(2m-1)$, consisting of m sheets which are topological spheres, each containing one circuit of each curve Φ and two base points of the pencil, and $(m-1)^2$ sheets which are topological tori, each containing two circuits of each curve of the pencil and no base points. This is constructed as a surface of revolution of order $2m$, the curves Φ being the meridian plane sections. Proof of existence is by induction on m. *P. Du Val* (London)

Gallarati, Dionisio 3943

Sul contatto di ipersuperficie algebriche di S_r lungo varietà $(r-2)$-dimensionali.
Univ. e Politec. Torino Rend. Sem. Mat. **22** (1962/63), 209–214 (1964).

La condition nécessaire et suffisante pour que deux hypersurfaces algébriques F et G de l'espace S_r aient le long de

n variétés à $r-2$ dimensions $C_1, C_2, \cdots, C_n$ des contacts respectivement d'ordre q_i-1 (≥ 0), $i=1, 2, \cdots, n$, les C_i étant simples pour F et G et $\sum_1^n q_i C_i$ étant leur intersection complète, est que l'on puisse associer à tout ensemble de n hypersurfaces $H_1, H_2, \cdots, H_n$ passant génériquement par la C_i de même indice, deux formes A et B, telles que la variété $A=B=F=G=0$ soit de dimension au plus $r-3$, et donnant l'identité: $AF+BG=H_1^{q_1}H_2^{q_2}\cdots H_n^{q_n}$.

Speranza, Francesco 3944

Le trasformazioni d'un piano in sè approssimabili con una trasformazione quadratica dotata d'una conica di punti uniti. (English summary)

Boll. Un. Mat. Ital. (3) **19** (1964), 193–205.

Author's summary: "Conditions are given for a point-transformation between two superposed planes to have, in a fixed point or in a general pair of corresponding points, at least an osculating, or semi-osculating, quadratic transformation with a conic of fixed points."
H. R. Müller (Braunschweig)

Subramanyam, S. S. 3945

On the general isotomic line-involution.

Math. Student **31** (1963), 47–50 (1964).

When two lines in a plane are conjugate with respect to all conics touching four given lines d forming a proper quadrilateral, then they form what is called a general isotomic involution; it can be considered as a dual of a general isogonal quadratic Cremona transformation. When one of the lines d is at infinity, the other lines d form the medial triangle of the diagonal triangle of the degenerate quadrilateral, and we speak of isotomic conjugate lines [the author, Math. Student **28** (1960), 70–73; MR **26** #659]. Now the line transformation is considered for the case of the net of conics S for which a given triangle is self-polar. Then the line transformation between pairs of asymptotes of the conics of the net is a one-to-one involution, hence a Cremona line involution. One of the results proved is that the asymptotes of a conic S are also the asymptotes of a definite conic which circumscribes the anti-medial triangle of any triangle self-polar to S.
D. J. Struik (Belmont, Mass.)

Demaria, Davide Carlo 3946

Sui caratteri dei sistemi lineari d'ipersuperficie segati sopra due varietà complementari dalle forme dello spazio ambiente.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 147–174.

The ideas and results of this work are closely related to those of a paper by Marchionna [Ann. Mat. Pura Appl. (4) **54** (1961), 159–199; MR **24** #A3547]. A leading part is played by the indices of irregularity σ^h ($h=1, 2, \cdots, d-1$) of an algebraic variety V_d.

The author considers two non-singular varieties V_d, V_d' of a complex projective space S_r which make up the complete intersection of $(r-d)$-forms of S_r having respective orders $n_1, n_2, \cdots, n_{r-d}$. It is further assumed that the variety $D=V_d\cap V_d'$ is non-singular and of dimension $d-1$.

With the usual notation, let (E_m), (E_m'), (E_m^*) denote the linear systems cut by the forms of order m on V_d, V_d' and D, respectively; let $\Delta_m, \Delta_m', \Delta_m^*$ be the relative deficiencies of these systems, and $\sigma^h(E_m)$, $\sigma^h(E_m')$, $\sigma^h(E_m^*)$ the corresponding indices of irregularity. According to convention, $\Delta_m=0$ for $m\leq 0$; also $\sigma^h(E_m)=0$ for $m<0$.

Writing $\rho=n_1+n_2+\cdots+n_{r-d}-r-1$, we first recall that, for $d=1$, $\Delta_m=\Delta_m'$ (Severi and Gaeta). The author establishes the following generalisation of this result:

$$\Delta_m=\sigma^{d-1}(E'_{\rho-m}),\qquad \sigma^1(E_m)=\sigma^{d-2}(E'_{\rho-m}),$$
$$\sigma^2(E_m)=\sigma^{d-3}(E'_{\rho-m}),\ \cdots.$$

It now readily follows that for $m>\rho$ the linear systems (E_m), (E_m') are complete and regular, a theorem previously obtained by other authors using different methods. Further, denoting by $g_k(W)$ the number of differential forms of the first kind of degree k attached to a variety W, the author shows that

$$\Delta_\rho'=g_{d-1}(V_d),\qquad \sigma^{d-h}(E_\rho')=g_{h-1}(V_d)$$
$$(h=2, 3, \cdots, d-1).$$

Finally, he obtains the relations

$$\Delta_m^*=\Delta_m+\Delta_m',\qquad \sigma^h(E_m^*)=\sigma^h(E_m)+\sigma^h(E_m'),$$
$$g_h(D)=g_h(V_d)+g_h(V_d')\qquad (h=1, 2, \cdots, d-2).$$
L. Roth (London)

Demaria, Davide Carlo 3947

Sui piani grafici esagonali.

Univ. e Politec. Torino Rend. Sem. Mat. **22** (1962/63), 115–158 (1964).

Nella prima parte di questa memoria (in parte monografica) l'autore espone con chiarezza e concisione quelle premesse e quelle definizioni (4-arco, reticolato intero, proprietà esagonale) sui piani grafici e sugli anelli ternari di M. Hall associati ai loro sistemi normali di coordinate affini, che occorrono al lettore per la comprensione delle parti successive.

Nella seconda parte si dimostra che ogni piano grafico esagonale π è localmente desarguesiano. Ciò significa che ogni 4-arco (quaterna di punti a 3 a 3 non allineati) di π ne genera un subpiano isomorfo ad un piano lineare su di un corpo primo di caratteristica $p\geq 0$ (questo teorema era già stato dimostrato dall'autore per $p>0$ [stessi Rend. **18** (1958/59), 43–52; MR **22** #12443]).

Nella terza parte l'autore considera i piani grafici esagonali per cui valgono anche i postulati dell'ordine e di Archimede. In particolare dimostra che condizione necessaria e sufficiente perchè un piano archimedeo sia desarguesiano è che esso contenga un subpiano esagonale.

Nella quarta parte si fa vedere come nei postulati che definiscono secondo D. Hilbert il piano proiettivo reale si possa sostituire l'ipotesi della validità della proprietà esagonale in un subpiano del piano stesso a quella della validità universale del teorema di Desargues.
E. Morgantini (Padova)

Salzmann, Helmut 3948

Zur Klassifikation topologischer Ebenen. II.

Abh. Math. Sem. Univ. Hamburg **27** (1964), 145–166.

The author continues his investigation of "flat" projective

planes **P** (topological planes whose point space is homeomorphic to that of the real projective plane) whose collineation group Γ is not too small. In his earlier papers [Math. Ann. **145** (1961/62), 401–428; MR **25** #2509; Arch. Math. **13** (1962), 98–109; MR **26** #666; Math. Ann. **150** (1963), 226–241; MR **27** #1922] it was shown (i) that **P** is desarguesian (and hence isomorphic to the real projective plane) if $\dim \Gamma > 4$, (ii) that **P** is a Moulton plane [Moulton, Trans. Amer. Math. Soc. **3** (1902), 192–195] if $\dim \Gamma = 4$, and (iii) all **P** with $\dim \Gamma \geq 3$ and Γ simple were completely determined. In the present paper the case $\dim \Gamma = 3$ and Γ non-simple is investigated, with topological group theory the main tool in the proofs. There are essentially five different possibilities for the configuration of the fixed elements of a closed connected three-dimensional subgroup Δ of Γ. In four of these cases the structure of **P** is completely determined, and the last case (where the fixed elements are an incident point-line pair) is postponed to a later publication. Except in the author's case (2), where there are two fixed points and two fixed lines of Δ, the plane **P** must again be desarguesian or moultonian. In case (2), however, there are other possibilities: **P** can then be coordinatized by a cartesian group [cf. Pickert, *Projektive Ebenen*, p. 90, Springer, Berlin, 1955; MR **17**, 399] whose additive group is that of the real numbers and whose multiplication depends on three real parameters.

P. Dembowski (Frankfurt a.M.)

André, Johannes 3949

Bemerkung zu meiner Arbeit "Über verallgemeinerte Moulton-Ebenen".

Arch. Math. **14** (1963), 359–360.

In Verbesserung einer früheren Arbeit [dasselbe Arch. **13** (1962), 290–301; MR **26** #667] wird gezeigt, daß die Bedingung III ($(as)b = a(sb)$, falls $s > 0$) bei der Kennzeichnung der verallgemeinerten Moulton-Ebenen (v.M.E.) fortzulassen ist, da sie nicht bei allen v.M.E. gilt und bei den Beweisen entbehrt werden kann. Ferner wird darauf hingewiesen, daß in Satz 4.3 (der genannten Arbeit) für die Umkehrung die Zugehörigkeit von u, U zur Unterebene benötigt wird.

G. Pickert (Giessen)

Pierce, William A. 3950

Collineations of projective Moulton planes.

Canad. J. Math. **16** (1964), 637–656.

Als affine Moulton-Ebene über dem Körper K wird eine affine Ebene bezeichnet, die sich (mit ϵ als Inzidenz) so bilden läßt: Punkte sind die Paare (x, y) aus $K \times K$, Geraden die Mengen $\{(x, y);\ x = c\}$, $\{(x, y);\ y = a \circ x + b\}$ $(a, b, c \in K)$; dabei wird die Verknüpfung $\circ$ mittels einer Untergruppe P vom Index 2 in der multiplikativen Gruppe von K und einer nichtidentischen umkehrbaren Abbildung ϕ von K auf sich folgendermaßen erklärt: $a \circ x = ax$ für $x \in P$, $a \circ x = \phi(a)x$ sonst. Damit nach diesem Verfahren überhaupt eine affine Ebene entsteht, muß ϕ gewissen Bedingungen genügen; ohne Einschränkung der Allgemeinheit wird darüber hinaus $\phi(0) = 0, \phi(1) = 1$ angenommen. Die projektive Abschließung einer affinen Moulton-Ebene wird als projektive Moulton-Ebene (im folgenden kurz: M.E.) bezeichnet; l_∞ ist ihre uneigentliche Gerade und Y_∞ der uneigentliche Punkt der Geraden $[0] =_{\mathrm{def}} \{(x, y);\ x = 0\}$. Es werden nun die Kollineationen einer M.E. auf eine M.E. bestimmt, zugleich mit den Bedingungen, wann zwei M.E. isomorph sind (d.h. eine Kollineation der einer auf die andere existiert). Ein Ausnahmefall liegt vor, wenn K die kleinstmögliche Ordnung, nämlich 9, besitzt. Nur in diesem Fall gilt nicht, daß jede Kollineation einer M.E. mit Y_∞ als Fixpunkt die Geraden $[0]$, l_∞ vertauscht oder festläßt. Besonders bemerkenswert ist das folgende Ergebnis: Genau dann, wenn eine M.E. (über K) eine den Punkt Y_∞ nicht festlassende Kollineation besitzt, ist K ein angeordneter Körper und die M.E. isomorph zu einer M.E. über K, bei der ϕ durch ein Element $q > 0$, $\neq 1$ von K bestimmt wird gemäß: $\phi(a) = a$ für $a > 0$, $\phi(a) = aq$ sonst.

G. Pickert (Giessen)

Lee, Boon-Phiew 3951

Plane configurations.

Bull. Math. Soc. Nanyang Univ. **1963**, 47–50.

A point and a line are incident if either the point lies on the line or the line passes through the point. A plane configuration is composed of p points and q lines such that every point is incident with a fixed number α of q lines and every line is incident with a fixed number β of p points. The symbol (p_α, q_β) denotes such a plane configuration whose dual is (q_β, p_α). If $\alpha = \beta$, the configuration is represented by (p_α) (self-dual configuration). (k_3) does not exist for $k = 7$. Whatever be the configuration, $p\alpha = q\beta$. The symbol $\{[q(q-1)/2]_2, q_{q-1}\}$ represents the only configuration for which every point of intersection of configuration lines is also a configuration point. The dual statement is satisfied by $\{p_{p-1}, [p(p-1)/2]_2\}$. If, finally, this is true for a self-dual configuration, the corresponding configuration is the triangle (3_2).

Alemany, R. E. 3952

Numerical values of certain constants related to mixed volumes of convex bodies. (Spanish)

Rev. Un. Mat. Argentina **21**, 113–118 (1963).

I. Fary [Illinois J. Math. **5** (1961), 425–430; MR **24** #A811] has obtained linear expressions for integrals of certain continuous, additive, translation-invariant functionals on the class of convex bodies in euclidean n-space, and in particular for certain "mixed volume" functionals. In the present paper the coefficients in these linear expressions are evaluated and used to prove a special case of a basic formula from integral geometry.

T. A. Botts (Charlottesville, Va.)

Shephard, G. C. 3953

Convex bodies and convexity on Grassmann cones. VIII. Projection functions of vector sums of convex sets.

J. London Math. Soc. **39** (1964), 417–423.

This paper uses the notation and terminology of the earlier papers in the same series (joint work of the author, H. Busemann and G. Ewald [Busemann, Ewald and Shephard, Math. Ann. **151** (1963), 1–41; MR **28** #522a; Arch. Math. **13** (1962), 512–526; MR **28** #522b; Shephard, J. London Math. Soc. **39** (1964), 307–319; MR **29** #520]).

Since it had been shown in an earlier paper in the series that two convex bodies can have the property that each has a convex projection function while their vector sum does not, it is natural to look for conditions under which it is possible to assert the convexity of a vector sum of convex sets about which we know nothing except their dimensions. A comprehensive result in this direction, too complicated to summarize here, is obtained in Theorem (10). An important tool in this work is the mixed projection function, introduced and studied at the beginning of the paper. This is the Minkowski mixed volume of the orthogonal projections of a number of convex sets on an r-flat, and its properties are of independent interest for their own sake. *A. M. Macbeath* (Birmingham)

Fejes Tóth, L. 3954

On the isoperimetric property of the regular hyperbolic tetrahedra. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 53–57.

The isoperimetric property of the regular tetrahedron is the fact that, of all tetrahedra having a given surface area, the regular one has the greatest volume. Two simple proofs are known for Euclidean space, but neither of them extends in any natural way to non-Euclidean spaces, and the case of elliptic space still presents an unsolved problem. For his ingenious proof of the isometric property in hyperbolic space, the author uses the following "moment lemma" [cf. the reviewer and the author, Quart. J. Math. Oxford Ser. (2) **14** (1963), 273–284, p. 277; MR **28** #1532]: Of all convex n-gons D (in the absolute plane) having a given area, the regular n-gon with center O maximizes the "moment" $\int_D f(r)\,dp$, where $f(r)$ is a strictly decreasing function of the distance r from a fixed point O to a variable point P of D, and dp is the element of area at P.

Klee, Victor 3955

On the number of vertices of a convex polytope.

Canad. J. Math. **16** (1964), 701–720.

Let P be a d-dimensional convex polytope in R^d, and let f_s denote the number of s-faces of P. It has been conjectured that

$$(1)\qquad f_0 \le \binom{f_{d-1}-[\frac{1}{2}(d+1)]}{f_{d-1}-d}+\binom{f_{d-1}-[\frac{1}{2}(d+2)]}{f_{d-1}-d},$$

$$(1^*)\qquad f_{d-1} \le \binom{f_0-[\frac{1}{2}(d+1)]}{f_0-d}+\binom{f_0-[\frac{1}{2}(d+2)]}{f_0-d},$$

the upper bound in (1*) being attained by the neighborly polytopes. Special cases of this conjecture have been established by various authors; e.g., Gale proved (1*) in case $f_{d-1}=d+2$ or $d+3$ [same J. **16** (1964), 12–17; MR **28** #516] (the present paper contains a history of known results). The author establishes (1*), in case $f_0 \ge (\frac{1}{2}d)^2-1$, not only for d-polytopes, but also for arbitrary Eulerian $(d-1)$-manifolds of Euler characteristic $1-(-1)^d$. For d-polytopes with $f_{d-1}\ge(\frac{1}{2}d)^2-1$, (1) follows by duality. Further, it is proved that for f_0 sufficiently large, among all d-polytopes with f_0 vertices, the neighborly polytopes maximize not only f_{d-1} but also f_s, $1\le s\le d-2$. Another result is the sharp inequality, $f_s \ge \binom{d+1}{s+1}+\binom{d-1}{s}$, $0\le s\le d-1$, if P is not a d-simplex. The author also proves some results pertaining to a closely related problem of Dantzig (to determine those convex sets with a maximum number of extreme points among all sets determined by m linear equations in n non-negative variables).

Bollobás, Béla 3956

Filling the plane with congruent convex hexagons without overlapping.

Ann. Univ. Sci. Budapest. Eötvös Sect. Math. **6** (1963), 117–123.

The problem of filling and covering the Euclidean plane with congruent (but not necessarily "equivalent") polygons was discussed by Kepler, Hilbert, and especially H. Heesch and O. Kienzle [*Flächenschluss*, Springer, Berlin, 1963; MR **27** #6185]. The author obtains some significant restrictions on the possible kinds of convex hexagons that can serve as a tile. In particular, he proves that if the plane can be filled with congruent hexagons, it can be filled with the same hexagons in such a way that each vertex belongs to exactly three of them. On the other hand, vertices of higher valency can easily occur; for instance, the author has drawn a pattern of irregular (but equilateral) hexagons having the symmetry of a regular pentagon. *H. S. M. Coxeter* (Hanover, N.H.)

Heppes, Aladár 3957

Filling of a domain by discs. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 363–371 (1964).

L. Fejes Tóth [Publ. Math. Debrecen **5** (1957), 119–127; MR **19**, 763] proved a theorem on the average area of isoperimetric convex discs packed in a convex hexagon. The proof is valid for the more general Theorem A stated below. Let $a_6(p)$ be the maximum possible area of a disc of perimeter $\le p$ lying in a regular hexagon of unit area. Then Theorem A states that if $D_1, \cdots, D_n$ are n convex discs of perimeter $\le p$ packed in a convex hexagon H, their average area does not exceed $a_6(p)$. The author proves that Theorem A is valid if (A*) the discs D_i are not necessarily convex, and (A**) the D_i are not necessarily convex and H is replaced by the union $\bigcup$ of n faces of a tessellation consisting of regular hexagons of unit area. In both cases the case of non-convex D_i is reduced to that of convex discs as follows. The D_i are first replaced by their convex hulls C_i, which are shown to intersect simply [in the notation of the reviewer and C. A. Rogers, J. London Math. Soc. **27** (1952), 304–314; MR **13**, 971]. Then, using the method of the paper by Rogers and the reviewer, the C_i are replaced by non-overlapping discs E_i such that $\bigcup C_i=\bigcup E_i$. Theorem A* follows at once from Theorem A, while A** is proved by replacing the E_i by non-overlapping polygonal discs whose average number of sides does not exceed six.

Strohmajer, J. 3958

Über die Verteilung von Punkten auf der Kugel.

Ann. Univ. Sci. Budapest. Eötvös Sect. Math. **6** (1963), 49–53.

The problem of arranging n points on the surface of a

sphere such that the minimum distance between them is maximum has attracted a lot of attention since its formulation by P. M. L. Tammes in 1930. The solution is known for $n \leq 12$ and $n = 24$; various cases having been disposed of by L. Fejes Tóth, P. M. L. Tammes, B. L. van der Waerden, K. Schütte, L. Danzer and R. M. Robinson. Good configurations for $n = 13$, 14, 15, 16, 17, 20, 25, 32, 33, 42 have been given by different authors. In this note good configurations for $n = 18$, 21, 22, 26, 30, 31, 52 due to the author, D. Kólya, J. Györffy and K. Böröczky are described. The density D_n of the corresponding packing of circles is compared with the upper bound Δ_n due to R. M. Robinson [Math. Ann. **144** (1961), 17–48; MR **24** #A3565]. *R. P. Bambah* (Columbus, Ohio)

Bambah, R. P.; Rogers, C. A.; Zassenhaus, H. 3959

On coverings with convex domains.

Acta Arith. **9** (1964), 191–207.

Let K be a closed, bounded, strictly convex region of area $a(K)$ in the real affine plane, $t(K)$ the area of the largest triangle contained in K, $\theta^*(K)$ the density of the best covering of the plane by translated replicas of K, and $\theta(K)$ the same with the restriction that the translations form a group. The authors prove that there exists a triangulation of the plane, with vertices at corresponding points in the replicas of K, such that each triangle has area $\leq t(K)$. They deduce that

$$\theta^*(K) \geq a(K)/\{2t(K)\}$$

and that, if K is centrally symmetric,

$$\theta^*(K) = a(K)/\{2t(K)\} = \theta(K).$$

They remark that the above inequality is sometimes (but not always) stronger than a similar inequality (using a hexagon instead of a triangle) due to Fejes Tóth [*Regular figures*, p. 167, Macmillan, New York, 1964; MR **29** #2705]. By suitably triangulating a polygonal region (their Theorem 5), they obtain a reasonably concise proof for a theorem which had been announced by Bambah and Rogers [J. London Math. Soc. **27** (1952), 304–314; MR **13**, 971]; their original proof was too complicated for publication. *H. S. M. Coxeter* (Hanover, N.H.)

Rogers, C. A. 3960

Covering a sphere with spheres.

Mathematika **10** (1963), 157–164.

Let N be the least number of its spherical caps of chord 2 required to cover the surface of a sphere of radius R, and let N^* be the least number of spheres of radius 1 required to cover the solid sphere of radius R. Upper bounds for N, N^* are obtained for $R > 1$, $n \geq 9$. The upper bound of N is of the type $N \leq f(n, R)\theta_R^{-1} + 1 = N_1$, where θ_R is the proportion of the surface of the sphere covered by one of the caps. This is used to obtain an estimate for N^* of the same type. An earlier result of the author [Mathematika **4** (1957), 1–6; MR **19**, 877] is used to obtain an estimate for N^* for $R \geq n/\log n$. This is also valid for the number of convex bodies K with centre O covering RK. Combined with the other estimate, this gives $N^* = O(n \log n R^n)$ if $R \geq n$, and $O(n^{5/2}R^n)$ if $R < n$.

To obtain the estimate of N above, the author proves (as in his earlier paper referred to above) that on the average $[N_1]$ caps of chord ξ (a certain length less than 2) cover a good proportion of the surface. Taking a configuration at least as good as the average and enlarging the caps to those of chord 2, he gets a covering of the surface by $[N_1]$ such caps. The problem of getting an estimate for N with $f(n, R)$ independent of R is open. *R. P. Bambah* (Columbus, Ohio)

Molnár, József 3961

Estensione del teorema di Segre-Mahler allo spazio.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 166–168.

The author defines a Segre-Mahler polytope to be one whose dihedral angles are $\leq 120°$. He makes the conjecture that, when equal spheres of radius r are packed in such a region of n-space, the density is $\leq d_n(r)$, where $d_n(r)$ is the density, inside a regular simplex of edge $2r$, of the packing of $n+1$ spheres of radius r with their centers at the vertices. In the notation of Schläfli [*Gesammelte mathematische Abhandlungen*, Band II, p. 177, Birkhäuser, Basel, 1953; MR **14**, 833] and the reviewer [Proc. Sympos. Pure Math., Vol. VII, pp. 53–71, esp. pp. 56–64, Amer. Math. Soc., Providence, R.I., 1963; MR **29** #1581], if the space is spherical or elliptic,

$$d_n(r) = \frac{\int_0^r \sin^{n-1}\rho\, d\rho}{\int_0^{\pi/2} \sin^{n-1}\rho\, d\rho}\,\frac{F_n(\alpha)}{F_{n+1}(\alpha)}, \quad \sec 2\alpha = n - 1 + \sec 2r;$$

if it is hyperbolic, there is a somewhat similar formula; and the Euclidean case can be derived by making r tend to zero.

This conjecture, which has already been established in the Euclidean case by Rogers [Proc. London Math. Soc. (3) **8** (1958), 609–620; MR **21** #847], is now proved for non-Euclidean 3-spaces. The author remarks that, in the spherical (or elliptic) case with $r = \pi/10$, the upper bound

$$d_3\left(\frac{\pi}{10}\right) = 12\left(1 - \frac{5}{\pi}\sin\frac{\pi}{5}\right) = 0.774\cdots$$

is attained by the "packing" of a single sphere of radius $\pi/10$ in one of the cells of the spherical honeycomb $\{5, 3, 3\}$ [the reviewer, Acta Math. Acad. Sci. Hungar. **5** (1954), 263–274, esp. p. 266; MR **17**, 523].

In the hyperbolic case, he mentions Florian's result that $d_3(r)$ is monotonic [Böröczky and Florian, ibid. **15** (1964), 237–245; MR **28** #3369] and deduces that, when equal spheres of radius r are packed in a Segre-Mahler polyhedron, the density is always less than

$$d_3(\infty) = \left(1 + \frac{1}{2^2} - \frac{1}{4^2} - \frac{1}{5^2} + \frac{1}{7^2} + \frac{1}{8^2} - \cdots\right)^{-1} = 0.853\cdots.$$

On some characteristic properties of the sphere. (Spanish. English summary)

Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 287–297.

Author's summary: "Theorem: (a) Let k be the curvature and τ the torsion of a closed curve C. Let s be the arc length of C and $f(k, \tau)$ a function of k and τ. If the relation

$$(1)\qquad \int_C f(k, \tau)\,ds = 0$$

holds for every closed spherical curve C, then $f=\varphi(k)\tau$, where $\varphi(k)$ is an arbitrary function of k. Reciprocally, if the function $f(k, \tau)$ has the form $f=\varphi(k)\tau$, then (1) holds for every closed spherical curve such that $k^{-1}\neq 0$ at every point. (b) Given a function $\varphi(k)$, if the relation

$$(2)\qquad \int_C \varphi(k)\tau\,ds = 0$$

holds for every closed curve C on a given surface Σ, then Σ is either a plane or a sphere. The curve C and the surface Σ are assumed of class C^3. This theorem generalizes previous results, see, e.g., G. Saban [Atti Accad. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **25** (1958), 457–464; MR **21** #5967].

Über das Raumbild eines ebenen Zwanglaufes (kinematische Abbildung von Blaschke und Grünwald).

Wiss. Z. Techn. Univ. Dresden **13** (1964), 7–16.

Die Arbeit bringt zunächst eine möglichst elementar gehaltene Einführung in die aus dem Jahre 1911 stammende kinematische Abbildung von W. Blaschke und J. Grünwald, bei der die Bewegungen der Ebene auf die Punkte eines quasielliptischen Parameterraumes übertragen werden. Hauptsächliches Hilfsmittel der Darstellung sind dabei geometrisch die Drehnetze der Cliffordschen Parallelen des quasielliptischen Raumes und die mit ihnen verbundenen Netzprojektionen, die sich, ebenso wie die Bewegungen, analytisch in einfacher Weise mittels komplexer Zahlen beschreiben lassen. Den Geraden g des Raumes sind dabei im kinematischen Bilde zwei Bildpunkte g_l, g_r zugeordnet und schneidenden Geraden g, g' entsprechen äquidistante Bildpaare ($g_lg_l'=g_rg_r'$).

Jeder stetig differenzierbare ebene Bewegungsvorgang ("Zwanglauf") besitzt dabei im quasielliptischen Bildraum als kinematisches Bild eine bestimmte Raumkurve, wobei dem System der Tangenten t der Raumkurve in der Bildebene die beiden Polkurven (t_l) und (t_r) der Bewegung entsprechen. Die Arbeit entwickelt die Bildkurven verschiedener wichtiger Bewegungsvorgänge, nämlich der elliptischen Bewegung und der symmetrischen Rollungen, insbesondere der verschiedenen Arten symmetrischer Kegelschnittsrollung, und geht zum Schluß auf die Konstruktion des kinematischen Raumbildes einer ebenen Bewegung ein, die durch zwei vorgegebene Punktbahnen festgelegt ist.

On the determination of the Burmester points for five positions of a moving plane.

Nederl. Akad. Wetensch. Proc. Ser. A **67** = *Indag. Math.* **26** (1964), 310–318.

Referring to the paper by F. Freudenstein and G. N. Sandor [J. Appl. Mech. **28** (1961), 41–49; MR **22** #10239], the author offers a direct analytical method to determine Burmester pairs, i.e., the combinations of a Burmester point with the center of its corresponding circle. The Burmester points are found as the intersections of two conics. In general, the configuration of the Burmester points is affinely related to that of the corresponding centers. If one Burmester point has its corresponding center at infinity, then the other Burmester points are collinear. Attention is paid to the case in which three of the five positions of the moving plane are parallel and to the cases in which all or a part of these positions are infinitesimally separated.

Finn, R.; Osserman, R. 3967

On the Gauss curvature of non-parametric minimal surfaces.

J. Analyse Math. **12** (1964), 351–364.

For a minimal surface S defined by $z=\phi(x, y)$, $x^2+y^2<R^2$, $\phi(0, 0)=0$, the authors continue the investigation of the value K of the Gauss curvature of S at the origin.

It is a result of E. Heinz [Nachr. Akad. Wiss. Göttingen Math.-Phys. Kl. Math.-Phys.-Chem. Abt. **1952**, 51–56; MR **14**, 885] that there is a universal constant c_0 such that $|K|\leq c_0/R^2$, and of E. Hopf [J. Rational Mech. Anal. **2** (1953), 519–522; MR **14**, 1119] that there is a universal constant c_1 such that $|K|\leq c_1/(R^2W^2)$, where W^2 is the value of $1+\phi_x^2+\phi_y^2$ at the origin. Further, R. Osserman [Trans. Amer. Math. Soc. **96** (1960), 115–128; MR **22** #12457] has shown that there is a universal constant c_2

such that $|K| \leq c_2/(d^2W^2)$, where d is the distance on S from the origin to the boundary of S.

It is now established that $|K| < g(W)/R^2$, where

$$g(W) = \frac{1}{2}\left(1+\frac{1}{W^2}\right)^2\left(\frac{\pi}{2}+\tan^{-1}\sqrt{\left(\frac{W^2-1}{2}\right)}\right)^2$$

and that in case $W=1$, i.e., in case S has a horizontal tangent plane at the origin, the value $g(1)=\pi^2/2$ is best possible.

As for best values for the constants c_0, c_1, c_2, it was previously known only that $c_0 \leq c_1 \leq c_2$ and that $7\frac{1}{8} \leq c_2 < 8$. The present result yields $\pi^2/2 \leq c_0 < (\pi+1/\pi)^2 < 6$, so that, in particular, $c_0 < c_2$.

Kongruenz der Gemeinlote von Erzeugenden einer rationalen windschiefen Regelfläche n-ten Grades. (Serbo-Croatian summary)

Glasnik Mat.-Fiz. Astronom. Društvo Mat. Fiz. Hrvatske Ser. II **17** (1962), 205–222 (1963).

Die Arbeit entwickelt zuerst Formeln für die Ordnung N und die Klasse M der Linienkongruenz, die von den Gemeinloten der Erzeugendenpaare einer rationalen windschiefen Regelfläche n-ten Grades gebildet wird. Man findet im allgemeinen Falle $N=(2n-1)(n-1)$ und $M=\frac{1}{2}(n-1)(3n-2)$. Die Gemeinlote der Erzeugendenpaare einer Regelschar des einschaligen Hyperboloids ($n=2$) bilden danach eine Linienkongruenz der Ordnung $N=3$ und Klasse $M=2$.

Im folgenden wird der Sonderfall der Kongruenz der Gemeinlote aller Erzeugendenpaare einer Regelschar eines einschaligen Drehhyperboloids betrachtet. Die Verfasserin geht dabei synthetisch vor und verwendet die konstruktiven Hilfsmittel der Darstellenden Geometrie, insbesondere der Perspektive. Wird eine Erzeugende e festgehalten, so bilden die sie treffenden Gemeinlote ein Plückersches Konoid, welches das Hyperboloid außer in seiner doppelten Leitlinie e und zwei Erzeugenden noch in einer Ellipse schneidet. Aus den Erzeugenden dieses Plückerschen Konoids kann die Kongruenz durch Drehung um die Hyperboloidachse gewonnen werden. Es wird noch eine weitere Zergliederung der Kongruenz in ein Büschel von Plückerschen Konoiden K, studiert und konstruktiv sowie figürlich erläutert.

Mit der Kongruenz der Gemeinlote der Erzeugendenschar eines (beliebigen) einschaligen Hyperboloids hat sich, wie der Autorin offenbar entgangen ist, schon W. Waelsch [S.-B. Math.-Natur. Cl. Akad. Wiss. Wien **96** (1887), II. Abt., 781–801] befaßt. Die große Bedeutung dieser Kongruenz für die Theorie der linearen Gewindemannigfaltigkeiten und ihre wichtigsten Eigenschaften findet man vor allem in E. Study [*Geometrie der Dynamen*, Teubner, Leipzig, 1902] entwickelt.

Dadažanov, N. 3971

Cyclic pairs of T_n complexes. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 793–803.

The author studies cyclic pairs of T_n complexes, which are generalizations of the well-known pairs of T complexes. They are introduced as follows.

Let there be given a one-to-one correspondence between the lines of two complexes G, G'. The plane π which corresponds to the point $M \in l$ in the main (normal) correlation of the G on the line l intersects the corresponding line l' in a point M'. To this point we can construct analogously a point M^* on the line l. The correspondence $\pi: M \to M^*$ is a projective transformation.

If π is the identity, the complexes G, G' form a T-pair. Cyclic pairs of T_n complexes are defined by the condition that π is a cyclic projective transformation of order $n \geq 2$.

Korovin, V. I. 3972

Stratification of two-parameter families of lines in a higher-dimensional projective space. (Russian)

Mat. Sb. (*N.S.*) **64** (**106**) (1964), 378–395.

L'ensemble formé de trois systèmes (l_i) ($i=1, 2, 3$) à deux paramètres de droites dans un espace projectif S_5 s'appelle cycle stratifiable si l'on peut attacher, à chaque système (l_i), une couche de surfaces de telle façon que les plans tangents, au points d'une droite l_i quelconque, passent par la droite l_{i+1} ($l_4 = l_1$) qui correspond à l_i dans une correspondance définie entre (l_i) et (l_{i+1}). Les cycles en question dépendent de 10 fonctions d'une variable. On démontre que les systèmes formant un cycle stratifiable sont des congruences R de droites. Les cycles qui renferment une congruence R donnée dépendent de 13 constantes arbitraires. On étudie les cycles qui admettent un système linéaire de droites ayant avec les congruences du cycle un contact du second ordre. Ces cycles dépendent de deux fonctions d'une variable. La généralité des cycles contenus dans un système linéaire en question dépendent d'une fonction d'une variable. Les transformations de Laplace des congruences d'un cycle stratifiable forment aussi des cycles stratifiables. Les cycles particuliers, définis par

l'égalité des invariants de Darboux des surfaces focales des congruences du cycle, dépendent de 26 constantes arbitraires et ils sont caractérisés par la propriété que les systèmes à deux paramètres des plans, déterminés par les triples de foyers correspondants des congruences du cycle, forment un couple stratifiable. Les recherches ultérieures sont consacrées à l'étude des transformations des systèmes à deux paramètres de droites moyennant des systèmes à un paramètre de droites situées sur une hyperquadrique. On arrive ainsi à une transformation T des congruences de droites dans S_3. A la fin du travail l'auteur donne un bref résumé des résultats relatifs à la stratification des systèmes à deux paramètres de droites dans S_{2n+1}. Quelques problèmes de ce mémoire ont été considérés dans un travail du rapporteur [Ann. Mat. Pura Appl. (4) **57** (1962), 239–255; MR **26** #4274]. *K. Svoboda* (Brno)

Picasso, E. 3980

Su certi sistemi ∞^2 di rette associati ai punti di una superficie differenziabile di un iperspazio.

Rend. Circ. Mat. Palermo (2) **12** (1963), 114–128.

The author extends in various ways Blaschke's results concerning a surface in a projective space P^4 and a hyperplane (or primal) P^3 in it; the tangent planes to the surface intersect P^3 in a congruence of lines; special properties of this congruence are projective properties of the surface and the hyperplane.

The configurations examined by the author are the following. (1) a surface V_2 in P^4 and a P^3: the congruences of the osculating planes to the curves of the conjugate system of V_2; (2) a V_2 in a P^5 and the intersections of the tangents to its parametric lines with a fixed P_4; (3) a V_2 with a double conjugate system in $P^{2\nu}$ and a fixed $P^{2\nu-1}$.

Superficie Φ e congruenze W.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **34** (1963), 620–627.

Erfüllen die inhomogenen Koordinaten $z^i = z^i(u, v)$ (mit $i = 1, 2, \cdots, n+2$) einer Fläche F des projektiven Raumes S_{n+2} $(n \geq 2)$ eine Laplacesche Differentialgleichung $z_{uv} = Pz_u + Qz_v$, so heißt die Fläche F vom (nicht parabolischen) Typus ϕ. Die Koordinatenlinien $u =$ konst. und $v =$ konst. von F bilden dann das charakteristische Netz obiger Differentialgleichung. Die Schmieg S_n, die die Linien $u =$ konst. von n-ter Ordnung berühren, schneiden einen festen S_3 allgemeiner Lage in den Strahlen einer Strahlkongruenz. Der Verfasser sucht die notwendigen und hinreichenden Bedingungen, denen die Fläche F und der S_3 genügen müssen, damit so eine W-Kongruenz erzeugt wird. Hierbei sind die Fälle n gerade oder n ungerade zu unterscheiden. *H. R. Müller* (Braunschweig)

Krasnodębski, R. 3982

A natural parameter of a curve in the symplectic space.
Ann. Polon. Math. 15 (1964), 189–194.

Nomizu's technique [Tôhoku Math. J. (2) **11** (1959), 106–112; MR **21** #5966] is used to define a natural parameter in a geometry given by an invariant form $\Omega = \sum_1^n x^i \wedge x^{n+i}$ of maximal rank n. The rank of a curve is the maximum dimension p such that the osculating spaces of dimension $k-1$ and k are in involution relative to Ω for $k \leq p$. This notion obviously is invariant in diffeomorphisms of high enough class. If the rank is constant on an arc, there is only one integral invariant θ such that

$$\Omega\left(\frac{d^p x}{d\theta^p}, \frac{d^{p+1}x}{d\theta^{p+1}}\right) = 1$$

for curves of class $\geqq 2p+1$.

Botella Raduán, F. 3984

On the proper differential of a topological space. (Spanish)
Rev. Mat. Hisp.-Amer. (4) **23** (1963), 75–83.

For the author a differential of a topological space is a sheaf of groups arising from a presheaf of local homeomorphism groups of the space. A proper differential can only occur on some special topological spaces, those which have a certain amount of local homogeneity. Proper differentials are associated with proper coordinate bundles, meaning those which have fibres homeomorphic to neighborhoods in the base space. This paper is concerned with the question of whether the sheaves depend finely on some neighborhood. However, this reviewer was unable to decipher the definition of this concept either through its statement or through the proofs. The definition as stated seems to be concerned with whether or not the part of a fibre bundle given by a coordinate function is a product bundle, but the reviewer's interpretation of a coordinate function is that it is always a representation of the part of the bundle as a product.

R. L. Bishop (Urbana, Ill.)

Botella Raduán, F. 3985

Differential connexion on a topological space and on a generalized manifold. (Spanish)
Rev. Mat. Hisp.-Amer. (4) **23** (1963), 181–188.

A presheaf of groups of homeomorphisms of neighborhoods of a topological space X prolongs to a coordinate bundle and gives a sheaf over X which is called a differential connexion with respect to the coordinate bundle. Parallel displacement in this bundle along a curve C in X is defined as being the collection of all those homeomorphisms between the fibres at the ends of C which are given by piecewise lifts of C with respect to given coordinate functions and their distortions by the local groups.

The definitions require that X be locally strongly ("fuertamente", abbreviated f) homogeneous. The definition of this concept is given in the author's paper [same Rev. (4) **22** (1962), 123–140], and here a characterization of it is given in terms of the existence of differential connexions and parallel displacement for them. In particular, a generalized manifold-α, defined in the next paper, satisfies the conditions.

R. L. Bishop (Urbana, Ill.)

Botella Raduán, F. 3986

A generalized manifold. (Spanish)
Rev. Mat. Hisp.-Amer. (4) **23** (1963), 189–193.

A generalized manifold is a separable locally strongly homogeneous topological space, which has been defined previously to be a space with a system of neighborhoods, each of which is homeomorphic to a homogeneous space A.

This paper is concerned with defining analogues to the tangent bundle, called a proper coordinate bundle, with the existence of differentials (which are certain sheaves of groups) and the existence of differentiable functions (those which induce mappings between differentials, e.g., all continuous functions). A more restrictive concept of generalized manifolds-α is defined by requiring A to be a topological ball, which means that all bundles over A are trivial, and it is pointed out that manifolds in the usual sense are generalized manifolds-α.

Quasilinears as characteristic objects of subgroups of the linear group. (Russian)
Trudy Sem. Vektor. Tenzor. Anal. **12** (1963), 63–70.

Let G be a subgroup of the full linear group $GL(n)$. Then G is isomorphic to a subgroup G of the group of all automorphisms of the centred affine n-space E_n. Hence there exists a geometric object in E_n that is the characteristic object of G (i.e., G is the group of all automorphisms of E_n preserving this object). Characteristic objects of subgroups of $GL(n)$ have been found till now in very special cases only [see, e.g., P. K. Raševskiĭ, same Trudy **10** (1956), 105–117; MR **18**, 907]. The author finds such objects for almost all one-parameter subgroups.

Let G be a one-parameter subgroup of $GL(n)$. If a coordinate system in E_n is fixed, then G is isomorphic to the group of transformations ${}^*x^\alpha = P_\beta{}^\alpha(t)x^\beta$, where x^β are coordinates of a point in E_n and t is a canonical parameter. The author introduces a special class of geometric objects in E_n—quasilinears—and proves that if the real parts of the eigenvalues of the matrix $\|dP_\beta{}^\alpha(0)/dt\|$ are not all equal to 0, then G has a quasilinear as its characteristic object. There are also found different properties of quasilinears (e.g., their Lie derivatives).

Fujimoto, Atsuo 3992

Conformal geometry of G-structures. I, II.

Tensor (*N.S.*) **15** (1964), 181–190; *ibid.* (*N.S.*) **15** (1964), 191–199.

Let M be a connected, paracompact n-dimensional manifold, G a Lie subgroup of $\mathrm{Gl}(n, R)$ with trivial intersection with R_+, where R is realized as the scalars in $\mathrm{Gl}(n, R)$, $H_s(M, G)$ a G-structure. Then the bundle $\hat{H}_s(M, \hat{G})$ obtained by enlarging the group of $H_s(M, G)$ to $\hat{G}=R_+\cdot G$ is the conformal extension of $H_s(M, G)$. G-structures $H_s(M, G)$ and $H_{s'}(M, G)$ are conformally equivalent if they have the same conformal extension, i.e., they differ by a positive C^∞ function on M. They are homothetically equivalent if the function is constant. A C^∞ transformation F of M is a conformal [homothetic] transformation of $H_s(M, G)$ if $\tilde{f}H_s(M, G)$ is conformally [homothetically] equivalent to $H_s(M, G)$, where $\tilde{f}$ is the prolongation of f to the bundle of bases ("frames" in the paper). An infinitesimal conformal [homothetic] transformation of $H_s(M, G)$ is a vector field X on M whose local one-parameter group of local diffeomorphisms consists of conformal [homothetic] transformations of $H_s(M, G)$.

A number of fairly simple results are established, including equivalent formulations of the above definitions, relations with structure tensors and connexions, and the fact that the bracket of infinitesimal homothetic transformations is an infinitesimal automorphism of the G-structure. *R. J. Crittenden* (Providence, R.I.)

de Barros, Constantino M. 3993

Espaces infinitésimaux; algèbre de Lie graduée associée à un espace infinitésimal de Cartan.

C. R. Acad. Sci. Paris **258** (1964), 3956–3959.

As the second in a series, this paper continues the algebraic construction of systems of modules, algebras, etc., derived by formal analogy from tangent vector fields, the algebra of C^∞ functions and the exterior algebra of a C^∞ manifold. The first part [same C. R. **258** (1964), 3624–3627; MR **28** #5396] deals with the more classical differential geometric structures; this second part sets up a system analogous to the theory of vector forms and derivations or differential forms of Frölicher and the reviewer [Nederl. Akad. Wetensch. Proc. Ser. A **59** (1956), 338–359; MR 18, 569].

A. Nijenhuis (Philadelphia, Pa.)

Espaces infinitésimaux; dérivée absolue.

C. R. Acad. Sci. Paris **258** (1964), 5330–5333.

In previous papers [same C. R. **258** (1964), 3624–3627; MR **28** #5396; see also #3993 above] the author developed a highly algebraic axiomatic theory of infinitesimal spaces. Here the notion of graduated infinitesimal translation is introduced, and a theory of linear connections and absolute derivation is developed in terms of the theory of infinitesimal spaces. *A. Goetz* (Wrocław)

Nguyen-Van-Hai [Nguyen Van Hieu] 3995

Conditions nécessaires et suffisantes pour qu'un espace homogène admette une connexion linéaire invariante.

C. R. Acad. Sci. Paris **259** (1964), 49–52.

The author gives a necessary and sufficient condition for a homogeneous space G/H to admit an invariant affine connection (Propositions 1 and 2). The condition is essentially the same as the one discovered by Wang [Nagoya Math. J. **13** (1958), 1–19; MR **21** #6001; see also Kobayashi and Nomizu, *Foundations of differential geometry*, Vol. I, p. 106, Interscience, New York, 1963; MR **27** #2945]. While Wang treats the general case where a Lie group is acting fibre-transitively on a principal bundle (with group K) and expresses the condition in terms of Lie algebras, the author treats the case where a Lie group G is acting fibre-transitively on the bundle of linear frames and expresses the condition in terms of Lie algebras and covariant differentiation. In Proposition 3,

the author gives a necessary and sufficient condition for G/H to admit an invariant torsion-free connection in terms of Lie algebras. *S. Kobayashi* (Berkeley, Calif.)

Kantor, I. L. 3996

A generalization of reductive homogeneous spaces. (Russian)

Dokl. Akad. Nauk SSSR **151** (1963), 1268–1270.

Let H be a subalgebra of the Lie algebra G. The homogeneous space corresponding to this pair (denoted by G/H) is said to be ν-reductive if there exists a direct sum decomposition $G=H_0+H_1+\cdots+H_\nu$ with $H_1+\cdots+H_\nu=H$ and $[H_i, H_0]\subset H_{i-1}$, for $i=1,2,\cdots,\nu$. (There seems to be a hypothesis missing, since Lemma 1, that $[H_i, H_k]\subset H_{i+k-1}$, does not always follow from the case $k=0$ when, e.g., H_0 is a direct summand of G and the H_i are renumbered.) If $\nu=1$, we have the usual reductive case, but if $\nu>1$ the bundle carries no invariant affine connection. Examples are discussed which arise from subgroups of differential groups of finite order. By "abelianizing" H_0, the author constructs an associated ν-reductive space M' and a fiber space U with base G/H and fiber M'. A canonical connection is defined in U and (following H. C. Wang [Nagoya Math. J. **13** (1958), 1–19; MR **21** #6001]) shown to be G-invariant. Projective and conformal connections are characterized among the 2-reductive canonical connections.

Libermann, Paulette 3997

Surconnexions. Propriétés générales.

C. R. Acad. Sci. Paris **258** (1964), 6327–6330.

Using the non-holonomic prolongations of the tangent bundle, the author introduces the notion of "semi-holonomic 'surconnexion' of order q" which reduces to an ordinary affine connexion if $q=1$. She also introduces the notion of geodesic of order q.

S. Kobayashi (Berkeley, Calif.)

Vanstone, J. R. 3998

Connections satisfying a generalized Ricci lemma.

Canad. J. Math. **16** (1964), 549–560.

Let $a_{ij}(x)$ be components of a tensor field of class C^1; let the symmetric and skew-symmetric parts of a_{ij} be denoted by s_{ij} and p_{ij}; let (s_{ij}) be non-singular and denote its reciprocal by (s^{ij}); define $(b^i{}_j)$ by the relation $b^i{}_j=s^{ir}p_{rj}$. The principal theorem proved is the following: There exists a connection $(\Gamma_j{}^i{}_k)$ such that the corresponding covariant derivative of (a_{ij}) vanishes if and only if the Jordan form of $(b^i{}_j)$ is constant.

T. J. Willmore (Liverpool)

Takano, Kazuo 3999

On Y. C. Wong's conjecture.

Tensor (N.S.) **15** (1964), 175–180.

An n-dimensional affinely connected space A_n for which $\nabla_m B^i{}_{jkl}=W_m B^i{}_{jkl}$ $(W_m\neq 0)$, where ∇_m denotes covariant differentiation with respect to the (symmetric) connection and $B^i{}_{jkl}$ is the curvature tensor, is called an A_n with recurrent curvature. Wong [Trans. Amer. Math. Soc. **102** (1962), 471–506; MR **24** #A3601] has conjectured that in an A_n with recurrent curvature, the tensor $\nabla_j W_k$ is symmetric if the Ricci tensor is symmetric. In the present paper, the author proves that in an A_n with recurrent curvature and symmetric Ricci tensor, $\nabla_j W_k$ is symmetric if there exists a vector ξ^i satisfying $W_i\xi^i=1$ and $W_h B^h{}_{ijk}\xi^i=0$. The proof depends upon use of the Bianchi identities and the integrability conditions of $\nabla_m B^i{}_{jkl}=W_m B^i{}_{jkl}$. *A. Fialkow* (Brooklyn, N.Y.)

Fava, Franco 4000

Connessioni composte e movimenti di ordine superiore.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 707–749.

A composed connection of order h is a system of operators, defined at each point x of a differentiable manifold V_n and associating with every ordered finite set $v_1,\cdots,v_p, v$ $(p\leq h)$ of tangent vectors at x a new tangent vector at x, denoted by $D_{v_1\cdots v_p}(v)$, which has the form

$$D_{v_1\cdots v_p}(v)^i = L^i_{jr_1\cdots r_p}v^jv^{r_1}\cdots v^{r_p},$$

where higher indices denote the components of a vector with respect to the canonical frame defined by a local coordinate system in the linear tangent space at x. Moreover, the functions L are subject to the transformation laws:

$$L^q_{mr_1}\theta^{q'}_q = \theta^{q'}_{mr_1}+L^{q'}_{m'r_1'}\theta^{m'}_m\theta^{r_1'}_{r_1}$$

$$\left(\theta^{q'}_q = \frac{\partial x^{q'}}{\partial x^q},\ \theta^{q'}_{mr} = \frac{\partial^2 x^{q'}}{\partial x^m\partial x^r},\cdots\right),$$

$$L^q_{mr_1r_2}\theta^{q'}_q = \theta^{q'}_{mr_1r_2}+L^{q'}_{m'r_1'}(\theta^{m'}_{mr_2}\theta^{r_1'}_{r_1}+\theta^{m'}_m\theta^{r_1'}_{r_1r_2})$$
$$+L^{q'}_{m'r_2'}\theta^{m'}_{mr_1}\theta^{r_2'}_{r_2}+L^{q'}_{m'r_1'r_2'}\theta^{m'}_m\theta^{r_1'}_{r_1}\theta^{r_2'}_{r_2}$$

when a coordinate transformation $x^{q'}=x^{q'}(x^1,\cdots,x^n)$ is performed.

With a composed connection certain curvature tensors are associated. The first of these is defined by

$$R^q_{mr_1r_2} = L^q_{mr_1r_2}-\partial_{r_2}L^q_{mr_1}-L^p_{mr_1}L^q_{pr_2},$$

and this tensor vanishes if and only if $D_{v_1v_2}$ coincides with the second-order absolute derivative defined by the connection $(L^q_{mr_1})$. The second curvature tensor is

$$R^q_{mr_1r_2r_3} = L^q_{mr_1r_2r_3}-\partial_{r_3}L^q_{mr_1r_2}-L^p_{mr_1r_2}L^q_{pr_3}$$
$$-L^p_{mr_1}R^q_{pr_2r_3}-L^p_{mr_2}R^q_{pr_1r_3}-L^p_{r_1r_2}R^q_{mpr_3}$$

and its vanishing is a further necessary and sufficient condition in order that $D_{v_1v_2v_3}$ also be defined by the connection $(L^q_{mr_1})$ by iteration of absolute derivation.

A composed connection defines a parallelism of tangent vectors, and a condition is given in order that the space admit a field of parallel vectors for a second-order composed connection $(L^q_{mr_1}, L^q_{mr_1r_2})$.

A family of paths is also associated with a composed connection. The paper concludes with a study of the motions of a composed connection of the second order, and it is proved that this group has a dimension at most equal to n^2+n. The projective motions are also defined.

G. Vranceanu (Bucharest)

Fava, Franco 4001

Connessioni tensoriali composte.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 773–789.

A composed tensor connection is introduced as a generalisation of the composed connections defined in the paper reviewed above [#4000]. When second-order tensors are considered, the author's generalisation is given by a system of two linear operators acting in the vector spaces of tensor squares $T_x \otimes T_x$ of the tangent vector spaces T_x of a differentiable manifold V_n, with respect to a local coordinate system. These operators are of the form

$$D_{v_1}(t)^{q_1 q_2} = L^{q_1 q_2}_{m_1 m_2 r_1} v_1^{r_1} t^{m_1 m_2},$$

$$D_{t_1}(t)^{q_1 q_2} = L^{q_1 q_2}_{m_1 m_2 r_1 r_2} t_1^{r_1 r_2} t^{m_1 m_2},$$

where $v_1 \in T_x$ and $t, t_1 \in T_x \otimes T_x$, $x \in V_n$. The functions L obey the transformation law

$$L^{q_1 q_2}_{m_1 m_2 r_1} \theta^{q_1'}_{q_1} \theta^{q_2'}_{q_2} = \partial_{r_1}(\theta^{q_1'}_{m_1} \theta^{q_2'}_{m_2}) + L^{q_1' q_2'}_{m_1' m_2' r_1'} \theta^{m_1'}_{m_1} \theta^{m_2'}_{m_2} \theta^{r_1'}_{r_1},$$

$$L^{q_1 q_2}_{m_1 m_2 r_1 r_2} = \partial_{r_1 r_2}(\theta^{q_1'}_{m_1} \theta^{q_2'}_{m_2}) + L^{q_1' q_2'}_{m_1' m_2' r_1'} \partial_{r_2}(\theta^{m_1'}_{m_1} \theta^{m_2'}_{m_2}) \theta^{r_1'}_{r_1}$$
$$+ L^{q_1' q_2'}_{m_1' m_2'} \partial_{r_1'}(\theta^{m_1'}_{m_1} \theta^{m_2'}_{m_2}) \theta^{r_2'}_{r_2}$$
$$+ L^{q_1' q_2'}_{m_1' m_2' r_2'} \theta^{m_1'}_{m_1} \theta^{m_2'}_{m_2} \theta^{r_2'}_{r_1 r_2}$$
$$+ L^{q_1' q_2'}_{m_1' m_2' r_1' r_2'} \theta^{m_1'}_{m_1} \theta^{m_2'}_{m_2} \theta^{r_1'}_{r_1} \theta^{r_2'}_{r_2}.$$

A curvature tensor is defined by

$$R^{q_1 q_2}_{m_1 m_2 r_1 r_2} = L^{q_1 q_2}_{m_1 m_2 r_1 r_2} - \partial_{r_2} L^{q_1 q_2}_{m_1 m_2 r_1} - L^{p_1 p_2}_{m_1 m_2 r_1} L^{q_1 q_2}_{p_1 p_2 r_2},$$

and also such geometrical notions are introduced as parallel transport and autoparallel curves. Similar considerations are sketched for the case when $T_x \otimes T_x$ is replaced by $T_x \otimes T_x^*$, where T_x^* is the dual vector space of T_x. *G. Vranceanu* (Bucharest)

Fava, Franco 4002

Connessioni tensoriali in spazi proiettivi curvi.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **97** (1962/63), 1064–1084.

Cet article est consacré à une étude des connexions tensorielles (c.t.) de E. Bompiani [Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) 1 (1946), 478–482; MR 8, 404], dans le sens de la possibilité d'extension à ces connexions de la notion de courbes autoparallèles pour une connexion (vectorielle) ordinaire. Après avoir rappelé quelques notions fondamentales relatives aux c.t., et notamment à celles de ces connexions de type (2, 0) [E. Bompiani, loc. cit.], l'auteur introduit des systèmes de courbes jouant, dans une variété V_n, pour la c.t. envisagée, le rôle d'autoparallèles. A partir du vecteur λ tangent à une courbe γ de V_n il construit le tenseur ξ, tangent à γ de type (2, 0) et deuxième puissance tensorielle de λ, et définit γ comme autoparallèle de V_n si le long de cette courbe est réalisé le transport parallèle de ξ. Contrairement à ce qui a lieu pour les connexions ordinaires, il n'existe généralement pas pour les c.t. de systèmes de courbes autoparallèles dont les courbes constituantes sont déterminées par un point et une direction de V_n. Mais, se plaçant dans un espace projectif courbe, l'auteur montre que de tels systèmes existent pour des classes particulières de c.t. (dites précisément associables à des espaces projectifs courbes) caractérisées par l'annulation d'un certain tenseur. L'étude de certaines de ces c.t. l'amène à établir quelques propriétés fondamentales pour l'édification d'une théorie projective des connexions tensorielles envisagées, et à donner quelques indications sur leur possibilité d'extension à des c.t. plus générales. *P. Vincensini* (Marseille)

Fulton, Curtis M. 4003

Clifford vectors.

Pacific J. Math. **14** (1964), 917–918.

In a Riemannian 3-space a Clifford vector field represented by the unit vector V^h is defined by $V_{i,j} = L\eta_{ijh} V^h$, where η_{ijh} is the covariant tensor whose components are $\sqrt{|g|}$ $[-\sqrt{|g|}]$ if (i, j, h) is an even [odd] permutation of (1, 2, 3), and zero otherwise, and L is a non-zero scalar. The author proves the theorem: The necessary and sufficient condition for a Riemannian 3-space to admit Clifford vector fields in all directions is that it be of constant positive curvature K with $K = L^2$.

R. Blum (Saskatoon, Sask.)

Zirilli, Francesco 4004

Ipersuperficie ricorrenti di uno spazio euclideo.

Ricerche Mat. **12** (1963), 181–194.

Given a Riemannian space V_n, this space is said to be recurrent (Schouten, Walker, Ruse) if we have the formulae

$$(1) \qquad R_{hijk,l} = k_l R_{hijk}$$

in which R_{hijk} is the curvature tensor and $R_{hijk,l}$ its covariant derivative. We see that for $k_l = 0$ we obtain the symmetric spaces of Cartan.

The aim of the paper is to show that if V_n is immersed in a Euclidean space E_{n+1}, then V_n is a cylinder (and can be considered as the orthogonal projection from a vertex E_{n-3} of a V_3). The proof given is a direct one by taking V_n to be defined by $z = z(x^1, \cdots, x^n)$ when $x^1, \cdots, x^n, z$ are orthogonal coordinates in E_{n+1}, and $z(x^1, \cdots, x^n)$ is of class C^4 and by using the relations of Bianchi for $k_l \neq 0$,

$$(2) \qquad k_l R_{hijk} + k_j R_{hikl} + k_k R_{hilj} = 0.$$

Nirmala, K. 4005

Curves and invariants associated with a vector field of a Riemannian V_n in relation to a curve C in a subspace V_m.

Proc. Nat. Inst. Sci. India Part A **29** (1963), 394–406.

Generalizing familiar notions of Riemannian geometry, Mishra and Krishna [Tensor (N.S.) 6 (1956), 125–131; MR 18, 761] defined the absolute curvature and normal curvature of a congruence of curves in a Riemannian manifold V_n with respect to a curve C in a subspace V_m. The definitions were given in terms of the derived vector of λ^a along C and its normal component in V_m, where λ^a is a unit tangent to a curve of the congruence. The present author considers the tangential component of this derived vector, leading to a definition of the geodesic curvature of the congruence λ^a with respect to C. Two possible generalizations of lines of curvature, principal curvatures and asymptotic lines, as well as their properties, are discussed. Finally, a general expression for the tendency of λ^a with respect to a curve C in V_m is obtained, and a number of its properties are given.

A. Fialkow (Brooklyn, N.Y.)

Nirmala, K. 4006

Differential invariants in Riemannian space.

Tensor (N.S.) **15** (1964), 282–291.

Let V_n be imbedded as a hypersurface of a Riemann space

V_{n+1} by the equations $y^\alpha = y^\alpha(x^i)$, and let $g_{ij}\,dx^i dx^j$ and $\Omega_{ij}\,dx^i dx^j$ be the first and second fundamental forms of V_n. Let (λ) be a congruence such that one curve of (λ) passes through each point of V_n, and let C be a curve in V_n. The author shows that various geometric quantities (e.g., the normal curvature and geodesic curvature of (λ) with respect to C) may be expressed by means of the two differential operators

$$\nabla = \frac{\partial y^\alpha}{\partial x^i} g^{ij} \frac{\delta}{\delta x^j}, \qquad \nabla^* = \frac{\partial y^\alpha}{\partial x^i} \Omega^{ij} \frac{\delta}{\delta x^j},$$

where $\delta/\delta x^j$ is the symbol of covariant differentiation. These operators also permit the author to generalize the Darboux functions associated with a surface to the case of a V_n in V_{n+1} and to discuss some of their properties.

Connessioni adattate a una struttura quasi prodotto.

Ann. Mat. Pura Appl. (4) **63** (1963), 133–150.

A unit tangent vector field in a Riemannian manifold gives rise to an almost product structure with perpendicular summands in each tangent space. The author chooses a special adapted connection, and she shows how covariant derivatives of vector fields with respect to this connection can be expressed very simply through the Riemannian covariant derivatives and the projection operators. Applications to relativity are anticipated.

A. Nijenhuis (Philadelphia, Pa.)

Radziszewski, K. 4009

Sur une condition de coïncidence des surfaces convexes isométriques.

Ann. Polon. Math. **15** (1964), 167–177.

Die klassische Theorie der regulären Flächen beweist den Eindeutigkeitssatz, daß zwei solche Flächen S_1 und S_2 deren erste und zweite Grundformen übereinstimmen, zueinander kongruent sind. Diese Bedingungen können durch die Forderungen abgewandelt werden, daß die beiden Flächen S_1 und S_2 zueinander isometrisch sind und in isometrisch entsprechenden Richtungen identische Normalkrümmungen haben. Bei konvexen Flächen kann die letzte Bedingung durch die Forderung ersetzt werden, daß isometrisch entsprechende Kurven gleiche Krümmungen besitzen.

In der vorliegenden Arbeit wird der obige Eindeutigkeitssatz für konvexe Flächen unter der Abänderung bewiesen, daß neben der Isometrie der Flächen die Identität der integralen Krümmungen isometrisch entsprechender Kurven gefordert wird. Der Begriff der integralen Krümmung $k(s)$ ist dabei im Sinne von A. D. Aleksandrov [Uspehi Mat. Nauk **2** (1947), no. 3 (19), 182–184] zu verstehen. Ist AB ein ebener konvexer Kurvenbogen und M einer seiner Punkte, ferner s die Länge des Bogens AM und $h(s)$ der algebraische Abstand des Punktes M von der Tangente der Kurve AB im Punkt A, schließlich $k(s)$ die integrale Krümmung des Kurvenbogens AM, so gilt dabei die Formel

$$h(s) = \int_0^s \sin k(x)\,dx.$$

Der Beweis des genannten Eindeutigkeitssatzes wird schrittweise auf 7 Hilfssätze gestützt. An verschiedenen Stellen werden dabei Ergebnisse von A. D. Aleksandrov [*Die innere Geometrie der konvexen Flächen* (russisch), OGIZ, Moscow, 1948; MR **10**, 619; deutsche Übersetzung, Akademie-Verlag, Berlin, 1955; MR **17**, 74] illustriert.

Mizusawa, Hideo 4010

On infinitesimal transformations of K-contact and normal contact metric spaces.

Sci. Rep. Niigata Univ. Ser. A No. 1 (1964), 5–18.

A K-contact space is a contact metric space with structure (ϕ, ξ, η, g), where ξ is a Killing vector with respect to the metric g. The author proves: (1) In a normal contact metric space of constant scalar curvature $R \neq n(n-1)$, $n > 3$, an infinitesimal conformal transformation is isometric; (2) Under the hypotheses of (1), an infinitesimal projective transformation is isometric if its associated vector ρ_i has the property $\xi^i\rho_i \neq 0$; (3) In a contact metric space, a vector v is an infinitesimal ϕ-transformation, $\mathfrak{L}_v\phi^i{}_j = 0$, if and only if $\mathfrak{L}_v\eta_i = \sigma\eta_i$ and $\mathfrak{L}_v g_{ij} = \sigma(g_{ij} + \eta_j\eta_i)$, and then σ is a constant; (4) In an Einstein contact space with $R \neq 0$, or in a K-contact space of constant scalar curvature $R \neq -(n-1)$, an infinitesimal ϕ-transformation is an automorphism; (5) In a K-contact space, an infinitesimal affine contact transformation is an automorphism. These are generalizations of some results in normal contact metric spaces [M. Okumura, Tôhoku Math. J. (2) **14** (1962), 398–412; MR **26** #4294].

Une propriété caractéristique des variétés kählériennes à courbure holomorphe constante.

C. R. Acad. Sci. Paris **259** (1964), 705–708.

Let V be a Kähler manifold with complex structure operator J. For every geodesic γ in V there is a Jacobi field ψ along γ such that $\psi(0) = 0$, $\psi'(0) = J\gamma'(0)$, where γ' is the tangent field to γ, and $\psi' = D_{\gamma'}\psi$, the covariant derivative of ψ. The Kähler manifold satisfies (CJ) if for every such ψ, $\psi = fJ\gamma'$ for some real-valued function f. The author shows that satisfying (CJ) is equivalent to having constant holomorphic curvature.

R. L. Bishop (Urbana, Ill.)

Hashimoto, Shintaro 4012

On differentiable manifold with almost quaternion contact structure.

Tensor (N.S.) **15** (1964), 258–268.

A quaternion almost complex structure on a $4m$-dimensional manifold was studied exhaustively by M. Obata and others [Obata, Japan. J. Math. **26** (1956), 43–77; MR **20** #1796a; J. Math. Soc. Japan **9** (1957), 406–416; MR **20** #1796b; Tôhoku Math. J. (2) **10** (1958), 11–18; MR **20** #1796c]. The author investigates almost quaternion structure on the $(4m+1)$-dimensional differentiable manifold, i.e., the (F, G, H, ξ, η)-structure on M^{4m+1}, where the tensor fields F_j^i, G_j^i, H_j^i, and the contravariant and covariant vector fields ξ^i and η_i over M^{4m+1} satisfy certain conditions. The manifold M^{4m+1} with the (F, G, H, ξ, η)-structure is said to have contact structure if there exists a 1-form $\eta = \eta_i dx^i$ over M^{4m+1} such that $\eta \wedge (d\eta)^{2m} \neq 0$. When a contact structure $\eta = \eta_i dx^i$ satisfies the relations $\partial_i \eta_j - \partial_j \eta_i = (1/\sqrt{3})(F_{ij} + G_{ij} + H_{ij})$, the (F, G, H, ξ, η)-structure is called a quaternion contact structure on M^{4m+1}. In this case the author considers the product manifold $M^{4m+1} \times R$, R a real line, and studies Nijenhuis tensors systematically, making use of the product manifold and pseudo-group of transformations. Thus he obtains 16 types of Nijenhuis tensors and many theorems concerning Nijenhuis tensors of this quaternion contact structure. His methods are analogous to those used by M. Obata and S. Sasaki [Sasaki and Hatakeyama, ibid. (2) **13** (1961), 281–294; MR **25** #1513].

T. Ohkubo (Kumamoto)

Hashimoto, Shintaro 4013

On differentiable manifold with almost quaternion contact structure. III.

Sci. Rep. Fac. Lit. Sci. Hirosaki Univ. **10** (1963), 5–9.

For the concept of an almost quaternionian contact structure (F, G, H, ξ, η), we refer to the author [same Rep. **8** (1961), 1–7; MR **27** #679a; ibid. 8 (1961), 79–87; MR **27** #679b]. By a method quite similar to that of M. Obata [Japan. J. Math. **26** (1956), 43–77; MR **20** #1796a], he shows that there is an affine connection, called an (F, G, H, ξ, η)-connection, with respect to which the tensors of the structure are covariant constant, and that the connection having a given torsion is unique. {Out of many misprints, F should be put ahead of $\mathring{\Gamma}$ in the first and second lines of the proof of Theorem 2.}

Y. Tashiro (Okayama)

Bonan, Edmond 4014

Tenseur de structure d'une variété presque quaternionienne.

C. R. Acad. Sci. Paris **259** (1964), 45–48.

An almost quaternionian (a.q.) structure (I, J, K) on V_m $(m = 4n)$ induces four projectors S, S', S'', S''' in the tangent space which are orthogonal to each other and whose sum is the identity. In $B = R^m \otimes R^{m*}$, $S(B)$ is identified with the Lie algebra $\underline{G}$ of $G = GL(n, H)$ and $\Gamma = S'(B) + S''(B) + S'''(B)$ is supplementary to $\underline{G}$ and invariant under G. Let $N_2 = B \otimes R^{m*}$, $N_G = \underline{G} \otimes R^{m*}$, $P = R^m \otimes \wedge^2 R^{m*}$, $A: N_2 \to P$, $V_G = A(N_G)$, $W = A(\Gamma \otimes R^{m*})$. Then W is a supplement of V_G in P. Applying results on G-structures due to D. Bernard [Ann. Inst. Fourier (Grenoble) **10** (1960), 151–270; MR **23** #A4094], the torsion tensor Σ of an a.q. connection is decomposed into $\Sigma = \Sigma_W + \Sigma_{V_G}$, and Σ_W is identified with the tensor T of the structure and $T = \frac{1}{2}([I, I] + [J, J] + [K, K])$. Moreover, on an a.q. Hermitian manifold, Σ_{V_G} is decomposed into its symmetric part Σ_U and its anti-symmetric part Σ_{V_g} in $\underline{G}$. $T + \Sigma_U$ is the tensor of the Sp(n)-structure.

Let γ be the Riemannian connection with respect to an a.q. Hermitian metric and ω the canonical a.q. connection. $\alpha = S\gamma$ is called the first canonical connection of Lichnerowicz and β, defined by $B_\alpha^\beta = \omega_\alpha^\beta + \frac{1}{2}g^{\beta\rho}\nabla g_{\rho\alpha}$, the second canonical connection. The torsion of β is equal to $T + \Sigma_U$. If, in a compact a.q. Hermitian manifold, an infinitesimal affine transformation with respect to α preserves the a.q. structure, the transformation is an isometry.

Y. Tashiro (Okayama)

Rizza, Giovanni Battista 4015

Strutture di Finsler di tipo quasi Hermitiano.

Riv. Mat. Univ. Parma (2) **4** (1963), 83–106.

The author studies Finsler metrics compatible with quasi-complex structures. Since the quasi-complex structure introduces almost a rotation group in the tangent planes, one expects the Finsler metrics to have special properties. In fact, the indicatrix of the Finsler metric is shown to be a complete circular domain in the terminology of Behnke and Thullen, hence in particular such a metric is symmetric (this is elementary from $J^2 = -1$). Also, there is a simple relation between the two kinds of cosines introduced in Rund's book [*The differential geometry of Finsler spaces*, Springer, Berlin, 1959; MR **21** #4462]. It follows that the Finsler metric and the quasi-complex tensor determine identical angular metrics in all two-dimensional characteristic elements. This leads immediately to quasi-hermitian Finsler structures. These structures are characterized by the symmetry of the usually unsymmetric cosine, and by a breaking up of the Euler relation for homogeneity of the metric form into complex and conjugate part. Finally, an averaging process due to Lichnerowicz is used to construct an invariant metric out of an arbitrary metric and a quasi-complex tensor. A non-trivial example is given which is invariant under a quasi-complex tensor field relative to a given field of elements of support but not relative to an arbitrary field of elements of support, and therefore is quasi-complex but not quasi-hermitian.

H. W. Guggenheimer (Minneapolis, Minn.)

Kawaguchi, Syun-ichi 4016

On a special Kawaguchi space of recurrent curvature.

Tensor (N.S.) **15** (1964), 145–158.

A special Kawaguchi space is an n-dimensional metric space in which the arc length of a curve $x^i = x^i(t)$ is given by

$$s = \int \{A_i(x, x')x''^i + B(x, x')\}^{1/p}\, dt.$$

A covariant derivative ∇ of tensors can be introduced in such a space and with it a curvature tensor $R_{jkl}^{\ \ \ \ i}$ and another tensor $K_{jk}^{\ \ \ i}$ defined by the identity

$$(\nabla_j \nabla_k - \nabla_k \nabla_j)v^i = -R_{jkl}^{\ \ \ \ i}v^l + K_{jk}^{\ \ \ l}\partial v^i/\partial x'^l$$

for an arbitrary contravariant vector v^i [see A. Kawaguchi, Trans. Amer. Math. Soc. **44** (1938), 153–167]. In this paper, the author obtains a few necessary conditions for a special Kawaguchi space to be of recurrent curvature, i.e., for it to satisfy the following condition:

$$\nabla_m R_{jkl}^{\ \ \ \ i} = v_m R_{jkl}^{\ \ \ \ i},$$

where v_m is some covariant vector. Among other results,

it is proved that in a special Kawaguchi space, (i) either v_m is a function of x^1 alone or $K_{jhk}{}^{\cdots h}x'^jx'^k=0$; and (ii) v_m satisfies

$$\nabla_q(\nabla_m v_n-\nabla_n v_m) = v_q(\nabla_m v_n-\nabla_n v_m),$$

$$v_q(\nabla_m v_n-\nabla_n v_m)+v_m(\nabla_n v_q-\nabla_q v_n)+v_n(\nabla_q v_m-\nabla_m v_q) = K_{qm}{}^{\cdots p}\partial v_n/\partial x'^p+K_{mn}{}^{\cdots p}\partial v_q/\partial x'^p+K_{nq}{}^{\cdots p}\partial v_m/\partial x'^p.$$

{Remark: The two identities in (ii) are analogous to those obtained by the reviewer for the case of linear connexions with zero torsion and recurrent curvature [ibid. **102** (1962), 471–506; MR **24** #A3601].}

Y.-C. Wong (Hong Kong)

Zaustinsky, Eugene M. 4017

Extremals on compact *E*-surfaces.

Trans. Amer. Math. Soc. **102** (1962), 433–445.

H. Busemann investigated systematically the theory of *G*-spaces (finitely compact metric spaces with locally unique geodesics) [*The geometry of geodesics*, Academic Press, New York, 1955; MR **17**, 779]. The author has extended many results of Busemann's study, which depend upon the symmetry of the metric, to the case without the assumption of symmetry [Mem. Amer. Math. Soc. No. 34 (1959); MR **22** #8462]. In the Riemannian case, if the genus of the surface is 1, the following results are known: (1) for a Euclidean straight line of the Poincaré model, there is a geodesic of the universal covering space which remains within a fixed distance of the given straight line; (2) a unique geodesic segment lies within a constant distance of the Euclidean straight line segment joining its endpoints. If the genus is >1, under the assumption of the Riemannian character of the metric, the following analogous results are known: (1′) for a hyperbolic straight line of the model, there is a geodesic which remains within a fixed distance of the straight line; (2′) a straight geodesic remains within a constant distance of some suitable hyperbolic straight line; (3′) the space possesses transitive geodesics.

In the present paper the author carries over the above results (1)–(2), (1′)–(3′) to *E*-spaces, i.e., non-symmetric Finsler spaces, using the notions of axis and axial motion (§§ 3, 4). He also proves that the universal covering space of a compact *E*-space with the divergence property is straight (§ 5). The last section is devoted to the question of the existence of transitive extremals on compact surface of higher genus, the distance being non-symmetric.

★Elementary general topology.

Prentice-Hall Mathematics Series.

Prentice-Hall, Inc., Englewood Cliffs, N.J., 1964. xi+174 *pp.* $7.95.

An undergraduate text with unusual precision, efficiency, and very good problems. The usual material is covered, and two fine chapters on nets and Peano spaces, respectively, are added. All concepts are well-motivated and studied to the extent practicable on this level.

J. Mayer (Albuquerque, N.M.)

Hammer, Preston C. 4019

Extended topology: Additive and subadditive subfunctions of a function.

Rend. Circ. Mat. Palermo (2) **11** (1962), 262–270.

The author continues his investigation of generalized closure functions. A set function f is subadditive if $f(X\cup Y)\subseteq f(X)\cup f(Y)$; it is additive if equality holds; it is isotonic if $X\supseteq Y$ implies $f(X)\supseteq f(Y)$. A function g is a subfunction of f if always $g(X)\subseteq f(X)$. Given f, it is established that maximum subadditive, additive and isotonic subfunctions of f exist. Various relations among these properties are established and high-order additivity properties are considered.

Sieber, J. L.; Pervin, W. J. 4020

Connectedness in syntopogenous spaces.

Proc. Amer. Math. Soc. **15** (1964), 590–595.

From the authors' introduction: "In his monograph [*Fondements de la topologie générale*, Gauthier-Villars, Paris, 1960; Akad. Kiadó, Budapest, 1960; MR **22** #4043], Császár introduced the notion of a syntopogenous space, which generalized the notions of a topological space, a proximity space, and a uniform space. Although Császár was able to obtain many of the usual theorems of general topology in this more general setting, the basic topological notion of connectedness was not introduced at all. Mrówka and Pervin [Proc. Amer. Math. Soc. **15** (1964), 446–449; MR **28** #4515] have discussed the concepts of $\mathscr{U}$-connectedness and δ-connectedness for uniform and proximity spaces, respectively. In this paper we shall give a definition for connectedness in syntopogenous spaces and show that it agrees with the corresponding properties in topological, proximity, and uniform spaces. Furthermore, we shall obtain some of the theorems concerning connected sets from general topology in this more general setting."

K. W. Kwun (Princeton, N.J.)

Lavallee, Lorraine D. 4021

Mosaic spaces, P_1-mappings, and property K.

Boll. Un. Mat. Ital. (3) **19** (1964), 95–97.

A collection $\{(X_a, \mathfrak{F}_a): a\in A\}$ is said to be a mosaic of topological spaces on a set X if and only if (i) each $(X_a, \mathfrak{F}_a)$ is a topological space; (ii) $X=\bigcup\{X_a: a\in A\}$; and (iii) for all subsets E of X and all $a, b\in A$, if $E\subseteq X_a$ and E is $\mathfrak{F}_a$-closed, then $E\cap X_b$ is $\mathfrak{F}_b$-closed. For a mosaic of topological spaces on X the mosaic topology $\mathfrak{F}$ is defined as follows: for all $E\subseteq X$, E is $\mathfrak{F}$-closed if and only if $E\cap X_a$ is $\mathfrak{F}_a$-closed for all $a\in A$. If each $(X_a, \mathfrak{F}_a)$ is a compact metric space, then the topological space $(X, \mathfrak{F})$ determined by the collection $\{(X_a, \mathfrak{F}_a): a\in A\}$ is called a mosaic space. An hereditary mosaic space is a mosaic space with the property that each subspace is a mosaic space.

A topological space $(X, \mathfrak{F})$ is said to have property K if for each point x and each subset E of X having x as an $\mathfrak{F}$-limit point, there exists an $\mathfrak{F}$-compact subset of $E\cup\{x\}$ which has x as an $\mathfrak{F}$-limit point.

The main theorem is that if $(X, \mathfrak{F})$ is a mosaic space, then $(X, \mathfrak{F})$ has property K if and only if $(X, \mathfrak{F})$ is hereditary. *S. Roy Schubert* (Riverside, Calif.)

Wang, Shu-tang 4022

Remarks on ω_μ-additive spaces.

Fund. Math. **55** (1964), 101–112.

A set X is called an ω_μ-additive space, where ω_μ is a regular initial ordinal number, if there is defined for every subset A of X a closure operation, $A \to \bar{A}$, satisfying the following axioms: (i) $\overline{\sum A_\xi} = \sum \bar{A}_\xi$ for every α-sequence of sets $\{A_\xi\}$, $0 \leq \xi < \alpha < \omega_\mu$; (ii) $\bar{A} = A$ for every finite subset A; (iii) $\bar{\bar{A}} = \bar{A}$ [R. Sikorski, Fund. Math. **37** (1950), 125–136; MR **12**, 727]. A topological space X is a $(U)_m$-space if its topology can be derived from a uniformity with a basis of power m, where m is the smallest possible. Definitions are also given for an ω_μ-metric and an ω_μ-metrizable topological space. The author obtains necessary and sufficient conditions for a $(U)_m$-space to be ω_μ-additive. Relationships between $(U)_m$-spaces and ω_μ-metrizable spaces are studied, and some necessary and sufficient conditions for an ω_μ-additive space to be ω_μ-metrizable are given. *E. Duda* (Coral Gables, Fla.)

Fröhlich, Otto 4023

Das Halbordnungssystem der topologischen Räume auf einer Menge.

Math. Ann. **156** (1964), 79–95.

Topologies on a set E form a subset Σ of the set $\mathfrak{B}(E)$ of sets of subsets of E. Σ is ordered ("ein Halbordnungssystem") by inclusion with the discrete topology $\mathfrak{B}(E)$ as greatest element. A maximal element of the ordered set $\Sigma - \{\mathfrak{B}(E)\}$ is called an ultraspace on E.

Let $\mathfrak{z}(a, \mathfrak{U}) = \mathfrak{B}(E - \{a\}) \cup \mathfrak{U}$ for a point a of E and an ultrafilter $\mathfrak{U}$ on E. If $\mathfrak{U} \neq \mathfrak{U}(a)$ (i.e., $\{a\} \notin \mathfrak{U}$), then $\mathfrak{z}(a, \mathfrak{U})$ is an ultraspace. All ultraspaces are obtained in this way, and a and $\mathfrak{U}$ are determined uniquely by $\mathfrak{z}(a, \mathfrak{U})$. The ultraspace $\mathfrak{z}(a, \mathfrak{U})$ is called principal if $\mathfrak{U} = \mathfrak{U}(b)$ for a point $b \neq a$ of E.

An automorphism of the ordered set Σ is determined by its action on ultraspaces. Any permutation of E induces an automorphism of Σ. If E is infinite, all automorphisms of Σ are obtained in this way. If E is finite with more than two elements, this is false.

Two ultraspaces $\mathfrak{z}(a, \mathfrak{U})$ and $\mathfrak{z}(b, \mathfrak{B})$ are homeomorphic if and only if there is a permutation of E which maps $\mathfrak{U}$ onto $\mathfrak{B}$. Homeomorphism classes of ultraspaces, and other classifications of ultraspaces, are discussed in detail; the results of this study cannot be reproduced here.

O. Wyler (Albuquerque, N.M.)

Hayashi, Eiichi 4024

Topologies defined by local properties.

Math. Ann. **156** (1964), 205–215.

Guided by certain properties of the first category sets of a topological space the author considers a family of sets $\mathfrak{p}$ of a topological space which contains the unit sets, is hereditary and finitely additive, and a set X is in $\mathfrak{p}$ if every point of X has a neighborhood U such that $U \cap X$ is in $\mathfrak{p}$. If (R, τ) is a T_1-space and $\mathfrak{p}$ is a family of subsets of R satisfying the conditions above, then, for each subset X of R, the set X^* consists of the points of R for which every neighborhood intersects X in a set not in $\mathfrak{p}$. Following a familiar procedure, the author defines a new topology τ^*, obviously containing τ, on R by taking as closed sets those sets X such that $X = X \cup X^*$.

A variant of the Cantor-Bendixson theorem is proved. Also, it is shown that, when (R, τ^*) is dense in itself, (R, τ) is connected, Hausdorff, and lightly compact if and only if (R, τ^*) satisfies the corresponding condition; and, if (R, τ^*) is regular, then $\tau = \tau^*$.

R. W. Bagley (Coral Gables, Fla.)

Levine, Norman 4025

Semi-open sets and semi-continuity in topological spaces.

Amer. Math. Monthly **70** (1963), 36–41.

A set which is a subset of the closure of its interior is defined to be semi-open. Several quite elementary properties of such sets are established (e.g., the image of a semi-open set under an open continuous map is semi-open). A function from a topological space to a topological space is defined to be semi-continuous if the inverse of each open set is semi-open. Again, some elementary properties are established (e.g., the set of points of discontinuity of a semi-continuous function from a topological space to a perfectly separable topological space is of the first category).

The choice of terminology ("semi-continuous") is unfortunate in that neither upper semi-continuous functions nor lower semi-continuous functions need be "semi-continuous". Also the term "semi-continuous" has been previously used as a property of binary relations [A. D. Wallace, Bull. Amer. Math. Soc. **51** (1945), 413–416; MR **6**, 278]. *F. Burton Jones* (Riverside, Calif.)

Bemerkungen zum Brückensatz.

Bayer. Akad. Wiss. Math.-Natur. Kl. S.-B. **1963**, *Abt. II*, 71–81 (1964).

Let X be a connected topological space such that X is normal and compact (i.e., bicompact). The author proves two "bridge" theorems: (I) If H and K are non-intersecting closed point sets (non-void), then some component of $X - (H + K)$ has a limit point in each of H and K, and (II) If H and K are non-intersecting closed point sets (non-void) and Q is a closed point set containing $H + K$ such that every limit point of a component of $X - Q$ belonging to Q must belong to $H + K$, then either $Q - (H + K)$ contains a connected point set having a limit point in each of H and K or $X - Q$ contains such a connected point set.

{The reviewer is somewhat puzzled by the interest in (II) as a "generalization" of (I). For if Q contains a continuum intersecting both H and K, then (II) follows from (I). If Q contains no such continuum, then Q is the sum of two non-intersecting closed point sets Q_H and Q_K containing H and K, respectively, and (II) again follows from (I). (Both theorems are immediate consequences of Theorems 43, 44 and 47 of Chapter I of R. L. Moore's *Foundations of point set theory* [revised edition, Amer. Math. Soc., Providence, R.I., 1962; MR **27** #709]. Moore's arguments apply without change.)}

The author also proves (I) and (II) when X is "locally

connected" instead of "normal and compact". (See the arguments for Theorems 2, 4 and 26 of Chapter II of Moore's book [loc. cit.].)

Dwinger, Ph. 4027

Amalgamation of Boolean spaces.

Nieuw Arch. Wisk. (3) **12** (1964), 25–31.

Let Y_γ, $\gamma \in \Gamma$, be a family of Boolean spaces, and let X be a Boolean space such that for every $\gamma \in \Gamma$ there exists an imbedding $h_\gamma : X \to Y_\gamma$. The author defines the "generalized Boolean topological sum of this family with the amalgamated Boolean subspace X" as a Boolean space Z such that (i) for every $\gamma \in \Gamma$ there exists an imbedding $f_\gamma : Y_\gamma \to Z$ such that for every pair $\gamma', \gamma'' \in \Gamma$, $f_{\gamma'} h_{\gamma'} = f_{\gamma''} h_{\gamma''}$, and (ii) if V is an arbitrary Boolean space and if g_γ, $\gamma \in \Gamma$, is a family of continuous maps, $g_\gamma : Y_\gamma \to V$, such that for every pair $\gamma', \gamma'' \in \Gamma$, $g_{\gamma'} h_{\gamma'} = g_{\gamma''} h_{\gamma''}$, then there exists a unique continuous map $g : Z \to V$ such that $gf_\gamma = g_\gamma$ for every $\gamma \in \Gamma$. He then proves that such a space Z always exists and is unique, as follows. Let Y be the ordinary topological sum of the Y_γ, and let Y^* be the quotient space of Y obtained by identifying those points of Y that are the images of the same point of X under the mappings h_γ. Then Z is the largest zero-dimensional Hausdorff compactification of Y^*.

Frink, Orrin 4028

Compactifications and semi-normal spaces.

Amer. J. Math. **86** (1964), 602–607.

A base Z for the closed sets of a T_1 space X is called a normal base if: (i) Z is a ring of sets, (ii) for every $F = \bar{F} \subset X$ and $x \notin F$ there exists $A \in Z$ such that $x \in A$ and $A \cap F = 0$, (iii) for any two disjoint $A, B \in Z$ there exists $C, D \in Z$ satisfying $A \subset C'$, $B \subset D'$ and $C' \cap D' = \varnothing$.

Theorem 1: A T_1 space X is completely regular if and only if there exists a normal base for the closed sets of X. Proof: In the completely regular T_1 space X the family of all zero-sets is a normal base for the closed sets of X. If Z is a normal base for the closed sets of a T_1 space X, then the family $w(Z)$ of all ultrafilters of Z with the Wallman topology [H. Wallman, Ann. of Math. (2) **39** (1938), 112–126] is a compactification of the space X. The author gives also a condition for the possibility of extending a real-valued function (and a continuous map into a compact space) from X to $w(Z)$. It is not known whether every compactification of the space X is of the form $w(Z)$.

Moors, R. 4029

Extensions d'un espace topologique associées à une famille de tamis; compactifications d'un espace topologique.

Bull. Soc. Roy. Sci. Liège **33** (1964), 59–81.

A sieve ("tamis") on a topological space $(E, \mathcal{T})$ is a nonempty subset $\mathcal{U}$ of $\mathcal{T}$, closed under finite intersections, such that $U \cup T \in \mathcal{U}$ whenever $U \in \mathcal{U}$ and $T \in \mathcal{T}$. A family $\{\mathcal{U}_i\}_{i \in I}$ of sieves on $(E, \mathcal{T})$ defines various "extensions" (K, θ) of $(E, \mathcal{T})$. In each case $K = E \cup I$, and (sample result, Theorem 2.5.2) the minimal extension has as base for θ all sets of the form $B \cup \{i : B \in \mathcal{U}_i\}$ $(B \in \mathcal{T})$.

Let $\mathcal{F}$ be a family of finite open covers for E, hereditary in a sense made precise by the author (p. 69). Each open cover i which is maximal with respect to the property $(\mathcal{V} \subset i \Rightarrow \mathcal{V} \notin \mathcal{F})$ gives rise naturally to a sieve $\mathcal{U}_i$ on E, and the minimal extension (K, θ) defined by the family $\{\mathcal{U}_i\}$ is a compactification of $(E, \mathcal{T})$. In case E admits a Wallman compactification, or a Stone-Čech compactification, these can be obtained by judicious choice of $\mathcal{F}$.

On real-valued proximity mappings.

Math. Ann. **154** (1964), 413–419.

The author defines and studies "realcompleteness" of a proximity space in analogy with realcompactness of a topological space.

L. Gillman (Rochester, N.Y.)

Dolčinov, D. 4031

A method of introducing the concept of proximity. (Russian)

C. R. Acad. Bulgare Sci. **17** (1964), 349–351.

If δ is a proximity relation on X, then a cover u of X is a δ-cover if $A\delta B$ implies that $A \cap C \neq \varnothing$ and $B \cap C \neq \varnothing$ for some $C \in u$. This note shows how the theory of proximity spaces may be axiomatized using the set of δ-covers instead of the proximity relation itself as the primitive notion.

D. Bushaw (Pullman, Wash.)

Heath, Robert W. 4032

Arc-wise connectedness in semi-metric spaces.

Pacific J. Math. **12** (1962), 1301–1319.

A semi-metric space differs from a metric space in that it need not satisfy the triangle inequality. The author studies in detail possible ways of extending to semi-metric spaces the arc theorem: A connected and locally connected Cauchy complete metric space is arc-wise connected. He shows that it cannot be generalized by replacing "metric" by "regular semi-metric" even in the presence of such properties as possessing a uniformity and being compactly connected, but can be extended to a class of spaces satisfying a more general completeness condition. In addition, topological characterizations are given for semi-metric, developable, and metric spaces. The proofs are for the most part related to R. L. Moore's proof of the arc theorem, and most results are related to their equivalent statements in terms of Moore's axioms.

L. K. Barrett (Knoxville, Tenn.)

Heath, R. W. 4033

Screenability, pointwise paracompactness, and metrization of Moore spaces.

Canad. J. Math. **16** (1964), 763–770.

Several relationships between the terms of the title are obtained, the first theorem being related to the assumption that $2^{\aleph_0} < 2^{\aleph_1}$. Some of the results proved are the following. (1) Every separable normal Moore space is metrizable if and only if every uncountable subspace M of E^1 contains a subset which is not an F_σ in M. (2) Let S be a topological space in which every closed set is a G_δ. If S is screenable, then S is pointwise paracompact. (3) A T_3-space S is a pointwise paracompact Moore space if and only if S has

a uniform base (in the sense of Aleksandrov). (4) A necessary and sufficient condition that a space S be screenable is that every open covering of S have a σ-star-countable refinement which is an open covering of S.

R. W. Bagley (Coral Gables, Fla.)

Morita, Kiiti 4034

Products of normal spaces with metric spaces. II.

Sci. Rep. Tokyo Kyoiku Daigaku Sect. A **8**, 87–92 (1964).

Part I appeared in Math. Ann. **154** (1964), 365–382 [MR **29** #2773]. The author introduces so-called basic coverings of a product $X \times Y$, and so-called special refinements of such coverings; the definitions of these concepts are too complicated to reproduce here. Some results relating these concepts to the normality of $X \times Y$ are obtained, and they have the following corollaries in whose statements the above concepts do not appear: (1) If Y is metrizable, then $X \times Y$ is paracompact and normal if and only if X is paracompact and normal and $X \times Y$ is countably paracompact and normal; (2) If Y is separable metrizable, then $X \times Y$ is regular Lindelöf if and only if X is regular Lindelöf and $X \times Y$ is countably paracompact and normal; (3) If Y is metrizable, then $X \times Y$ is normal for any countably paracompact normal space X if and only if Y is a countable union of locally compact subsets. {Note: In the author's terminology, neither paracompact nor normal imply Hausdorff.}

E. Michael (Seattle, Wash.)

Mioduszewski, J. 4035

Mappings of inverse limits.

Colloq. Math. **10** (1963), 39–44.

The author proves several generalizations for inverse systems of polyhedra of the following well-known theorem. If the sequence $f_1, f_2, \cdots$ maps the inverse sequence $\{X_m, \pi_n^m\}$ to the inverse sequence $\{Y_m, \sigma_n^m\}$ (i.e., for $m < n$, $f_m\pi_m^n = \sigma_n^m f_n$), then the induced transformation f between the inverse limits is continuous. The generalizations involve replacing equality of $f_m\pi_m^n(x)$ and $\sigma_m^n f_n(x)$ for all x in X_m with suitable uniform closeness conditions. Some of these more or less "technical" results were applied in the author's proof that every snakelike continuum is the continuous image of the pseudo-arc [Fund. Math. **51** (1962/63), 178–189; MR **26** #1859]. (A stronger result on the images of the pseudo-arc has appeared in papers by A. Lelek [Fund. Math. **51** (1962/63), 271–282; MR **26** #742] and L. Fearnley [Trans. Amer. Math. Soc. **111** (1964), 380–399; MR **29** #596].)

{Theorems 2′ and 4′ evidently need to have added to the hypothesis that for some integer pair m, n there is a map f in $\mathcal{F}$ from X_m to Y_n. On page 40, line 18 from bottom, m_{i+1} should be n_{i+1}.} *R. Bennett* (Galesburg, Ill.)

Pasynkov, B. A. 4036

On a class of mappings and on the dimension of normal spaces. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 356–376.

This paper contains numerous results (25 theorems) concerning the comparison of various notions of dimension (dim, ind, Ind), the behaviour of dimension under mappings of different types, and results concerning the dimension of quotient spaces of locally bicompact groups. The unifying concept in the paper is the notion of mappings $f: X \to Y$ of class (k, Ω), where $k \geq 0$ is an integer and Ω is a class of open coverings of the space X. These are maps with the property that, for every $\omega \in \Omega$ and every point $y \in Y$, there exists a neighborhood $O(y)$ such that $f^{-1}O(y)$ admits an open covering of order $\leq k+1$ which refines ω. The most important case is the case $(0, \Omega)$, which generalizes the uniformly 0-dimensional mappings of M. Katětov [Dokl. Akad. Nauk SSSR **79** (1951), 189–191; MR **15**, 145], the (U, V)-uniformly 0-dimensional mappings of K. Nagami [Proc. Japan Acad. **37** (1961), 207–211; MR **24** #A533] and the "disintegrating" mappings of A. Zarelua [Dokl. Akad. Nauk SSSR **144** (1962), 713–716; MR **26** #5541].

Here we can state only some of the results. Theorem 4: Let X be a normal space which admits a mapping $f: X \to Y$ of type $(0, \Omega)$ onto a metric space Y, Ω containing all finite coverings of X. Then $\dim X = \operatorname{Ind} X$. The proof depends on the theorem of M. Katětov and K. Morita that dim and Ind coincide for metric spaces, and on the fact that every mapping $f: X \to Y$ into a metric space Y admits a factorization through another metric space Z with $\dim Z \leq \dim X$ [the author, ibid. **150** (1963), 488–491; MR **27** #2955]. Theorem 7: Let X be a normal space having the property that $\dim F \leq \operatorname{ind} F$ for all closed subsets $F \subseteq X$. Furthermore, let X admit a mapping $f: X \to Y$ of type $(0, \Omega)$ onto a metric space Y, Ω being a "fine" system of coverings in the sense that, for every $x \in X$ and every neighborhood $O(x)$, there exists an $\omega \in \Omega$ such that the star $\mathrm{St}_\omega(x) \subseteq O(x)$. Then $\dim X = \operatorname{ind} X = \operatorname{Ind} X$.

The author also introduces and studies mappings called n-peripheral. $f: X \to Y$ is 0-peripheral provided it is of type $(0, \Omega)$, where Ω is a "fine" system of coverings of X. f is n-peripheral provided every point $x \in X$ can be surrounded by arbitrarily small neighborhoods with the property that f is $(n-1)$-peripheral on their boundaries. Theorem 15: If $f: X \to Y$ is n-peripheral, then $\operatorname{ind} X \leq \operatorname{ind} Y + n$. In the last section the author establishes several factorization theorems of the following type. Theorem 20: For paracompact spaces Z, every mapping $f: X \to Z$ of type $(0, \Omega)$ admits, for every $\omega \in \Omega$, a factorization into an ω-mapping $g: X \to Y$ and a mapping $h: Y \to Z$ with discrete counter-images $h^{-1}(z)$ of cardinality $k(h^{-1}(z)) \leq k(\omega)$.

Gropen, Arthur L. 403

Special homeomorphisms in the functional spac $\mathscr{C}(X, I_{2n+1})$.

Duke Math. J. **28** (1961), 629–637.

The author makes the following extensions of results o J. H. Roberts [same J. **8** (1941), 565–574; MR **3**, 138 and M. K. Fort, Jr. [Proc. Amer. Math. Soc. **7** (1956) 539–542; MR **18**, 918]. (1) Let M be a separable metri space of dimension n, n finite, and let $\{T_n^i\}_{i=1}^\infty$ be a arbitrary countable family of n-hyperplanes in I_{2n+} (the intersection of n-hyperplanes with the cube I_{2n+1} Then there exists a mapping f from M into I_{2n+1} with th following properties: (i) for any k-hyperplane T_k i I_{2n+1} $(n+1 \leq k \leq 2n+1)$, we have $\dim(f(M)^- \cap T_k)$: $k-n-1$; (ii) f is a homeomorphism from M into I_{2n+1} (iii) for every $i = 1, 2, \cdots$, $f(M)^- \cap T_n^i$ is empty. Furthe the set of functions having properties (i)–(iii) contains

dense G_δ in the functional space $\mathscr{C}(M, I_{2n+1})$ (uniform topology). (2) Let X be separable metric and A a closed subset of X such that $\dim(X-A) = m \geq n$, m finite. Then, if f is a mapping from A into I_n, there is an extension F of f over X such that $\dim(X-A) \cap F^{-1}(y) \leq m-n$ for all y. Further, the set of such extensions is dense in the space of all extensions of f over X (with uniform topology).

R. W. Bagley (Coral Gables, Fla.)

Anderson, R. D. 4038

Homeomorphisms of 2-dimensional continua.

General Topology and its Relations to Modern Analysis and Algebra (Proc. Sympos., Prague, 1961), *pp.* 55–58. *Academic Press, New York; Publ. House Czech. Acad. Sci., Prague,* 1962.

A technique for the construction of homeomorphisms between spaces is described. The ideas are then used to characterize two classes of two-dimensional homogeneous continua. The method of description is suggested by a refinement sequence of finite, closed, non-overlapping, connected partitions of the space with homeomorphic elements. The basic definitions used are the following. A triple of sequences $(\{F_i\}, \{\phi_i\}, \{\alpha_i\})$ is an inverse incidence system provided that, for each i, (1) F_i is a finite set; (2) ϕ_i is a map of F_{i+1} onto F_i; (3) α_i is a reflexive and symmetric binary (incidence) relation of F_i; and (4) if $(a, b), (b, c) \in \alpha_{i+1}$ then $(\phi_i(a), \phi_i(c)) \in \alpha_i$. The pair $(\{F_i\}, \{\phi_i\})$ is an inverse system whose inverse limit L is a zero-dimensional compact metric space.

Let R be a binary relation on L defined by $(\{f_i\}, \{f_i^0\}) \in R$ provided that, for each i, $(f_i, f_i^0) \in \alpha_i$. Using condition (4) of the definition above, it follows that R is an equivalence relation and that the set L of equivalence classes defined by R is an upper semicontinuous decomposition $\hat{L}$ of L. The collection $\hat{L}$ (topologized) is called the inverse incidence limit of (F_i, ϕ_i, α_i). It is interesting to note that only binary incidence relations are needed for this structure.

The basic problem discussed in this paper is to determine conditions on two sequences under which their inverse incidence limits are homeomorphic.

Henderson, George W. 4039

The pseudo-arc as an inverse limit with one binding map.

Duke Math. J. **31** (1964), 421–425.

A continuous function f from $[0, 1]$ onto $[0, 1]$ is constructed such that the inverse limit with f as the only binding map is a pseudo-arc. The construction is rather complex. The author states that this unusual representation may help in solving some of the open questions concerning the pseudo-arc. The assertion is made, without proof, that the construction may be modified in such a way that the map is "infinitely differential".

{There are several misprints. The statement of Lemma 1 should begin "There is a map f". On line 6 from the bottom, page 424, V should be v. It is not clear to the reviewer that the hypotheses of Lemma 2 are sufficient to imply the limit function is continuous at 1, as is stated after Lemma 2; the construction as given is sufficient, however. In the construction of $f_1, f_2, \cdots$ it appears that some further condition like $f_k^{-1}(l_k) < L_{k+1}$ needs to be imposed in choosing L_{k+1}.} *R. Bennett* (Galesburg, Ill.)

Hedrlín, Z. 4040

Remark on partial mappings.

Comment. Math. Univ. Carolinae 4 (1963), 93–97.

Let F be a semigroup of mappings under composition. For $f \in F$ and a set Y, let $f \| Y = f | (Y \cap f^{-1}(Y))$. If h is a mapping such that $h(x_1) = h(x_2)$ implies $h \circ f(x_1) = h \circ f(x_2)$ for $x_1, x_2 \in \operatorname{dom} f$, define $(h \times f)(x) = h \circ f(y)$, where $h(y) = x$. The author gives elementary conditions under which $f \to f | Y$, $f \to f \| Y$, and $f \to h \times f$ are homomorphisms.

Remark on topological spaces with given semigroups.

Comment. Math. Univ. Carolinae 4 (1963), 161–163.

A semigroup with identity that has cardinality less than the first inaccessible cardinal is isomorphic with the semigroup of all local homeomorphisms of some T_0 topological space into itself. *K. A. Ross* (New Haven, Conn.)

Baayen, P. C.; Hedrlín, Z. 4042

Commutative polynomial semigroups on a segment.

Comment. Math. Univ. Carolinae 4 (1963), 173–179.

If X is a subset of the real line R, an X-cps is, by definition, a commutative semigroup S of mappings of X into itself, all elements of which are restrictions to X of real polynomials on R. If S contains every continuous map that commutes with all $f \in S$, then S is called maximal; S is entire if it contains restrictions to X of polynomials of every non-negative degree. Semigroups S_i on X_i $(i = 1, 2)$ are equivalent if there is a homeomorphism τ of X_1 onto X_2 such that $S_2 = \{\tau \circ f \circ \tau^{-1} : f \in S_1\}$. The authors determine, up to equivalence, all entire $[0, 1]$-cps and establish which of these is maximal. Results on $[-1, 1]$-cps and R-cps are also given. *K. A. Ross* (New Haven, Conn.)

Ogurcov, N. I. 4043

A class of topological semigroups on a direct product. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 887–890.

Let $S = \prod X_\alpha$ be a product of topological Hausdorff semigroups. The author states some elementary facts relating subsemigroups, ideals, etc., in S with these objects in the factors X_α. Theorem: A topological semigroup T with underlying space $S = \prod X_\alpha$ is topologically isomorphic with a product semigroup on S if there exist continuous homomorphisms ϕ_α of T onto topological semigroups on each factor X_α that are independent. As an example, consider the manifold $A = S^{n-1} \times I$ with boundary B, where S^{n-1} is the closed unit cube in Euclidean n-space. If T is a topological semigroup with identity on A and B is a subsemigroup, then T is topologically isomorphic with a product semigroup on A.

ALGEBRAIC TOPOLOGY

Saaty, Thomas L. 4045

The minimum number of intersections in complete graphs.

Proc. Nat. Acad. Sci. U.S.A. **52** (1964), 688–690.

Let G_n denote the complete graph on n vertices. Let I_n denote the minimum number of edge intersections when G_n is drawn in the plane (in such a way that at most two edges intersect at any point other than a vertex of G_n). The author exhibits a drawing of G_n which shows that an upper bound of I_n is given by

$$M_n = n(n-2)^2(n-4)/48, \qquad n \text{ even},$$
$$= (n-1)(n-3)(n^2-4n+1)/48, \qquad n \text{ odd}.$$

He states without proof:

$$M_n' = n(n-2)^2(n-4)/64, \qquad n \text{ even},$$
$$= (n-1)^2(n-3)^2/64, \qquad n \text{ odd},$$

is a (better) upper bound; furthermore, if there exists a minimal-intersection representation of G_n which has the property that it contains a minimal-intersection representation of G_{n-k} for each even $k<n$, then $I_n = M_n'$.

Erdős, P.; Moser, L. 4046

A problem on tournaments.

Canad. Math. Bull. **7** (1964), 351–356.

The authors establish some existence theorems for tournaments. A typical result runs as follows. "Let $n > (\log 2+\varepsilon)k^2 2^k$. Then there exists a positive $\alpha = \alpha(\varepsilon)$ so that for each $l \leq k$ and every choice of l players $x_1, x_2, \cdots, x_l$, each of the 2^l classes into which the remaining $n-l$ players are divided (two players are in the same class if they perform in an identical way against the players $x_1, x_2, \cdots, x_l$) contains more than $\alpha n/2^l$ players, for all but $o(2^{n(n-1)/2})$ of the tournaments."

W. T. Tutte (Waterloo, Ont.)

Beatty, J. C.; Miller, R. E. 4047

On equi-cardinal restrictions of a graph.

Canad. Math. Bull. **7** (1964), 369–375.

The authors define a "k-equi-cardinal restriction" of a graph G as a subgraph of G which includes all the vertices, and in which each component has exactly k vertices. Their problem is to find a minimum integer d such that every regular graph of $n = mk$ vertices and degree (valency) $\geq d$ has a k-equi-cardinal restriction.

The authors obtain the following results. If m is even, then $d = (n/2)-1$. If m is odd and k is even, then $d = n/2$. If m and k are odd and $(n+1)/2$ is even, then $d = (n-1)/2$. In the remaining case $d = (n-3)/2$. They remark that "little is known of the problem if one adds the hypothesis that the graph be connected".

Harary, F. 4048

Recent results in topological graph theory.

Acta Math. Acad. Sci. Hungar. **15** (1964), 405–411.

This is an article reviewing some recent work (mostly by the author and collaborators) concerning the embeddability of graphs in surfaces. The main problems dealt with are the determination of the genus or thickness of complete graphs, complete bicolored graphs, and cubes. The results range in calibre from trivial (such as various consequences of Euler's polyhedral formula) to impressive (e.g., the theorem that the genus of a graph is the sum of the genera of its blocks). There is an abundance of interesting open questions, such as the determination of the genus of the complete graph K_n for $n \equiv 1, 2, 6, 8, 9, 11 \pmod{12}$. The bibliography lists nearly all recent work on the subject.

G. Sabidussi (Hamilton, Ont.)

Harary, Frank; Prins, Geert; Tutte, W. T. 4049

The number of plane trees.

Nederl. Akad. Wetensch. Proc. Ser. A **67** = *Indag. Math.* **26** (1964), 319–329.

A (planted) plane tree is a tree T embedded in the plane (with an end vertex of T distinguished as root). Two (planted) plane trees are considered to be isomorphic if there is an orientation-preserving homeomorphism of the plane onto itself which maps one tree onto the other (and root onto root). In the first part of the paper an explicit formula is obtained for the number of non-isomorphic planted plane trees with n vertices. This is simply another in a long series of applications of Pólya's well-known enumeration method. Contrary to the belief of the authors (if their choice of title is any indication) this reviewer feels that the second part of the paper is by far the more important. For $n \geq 2$ denote by P_n the set of all non-isomorphic planted plane trees with n vertices, and by T_n the set of all non-isomorphic planted trivalent plane trees (i.e., trees in which every vertex has degree 1 or 3). It is shown that there is a natural one-one correspondence f_n between P_n and T_n for all n. Both the construction of f_n and the proof that it is one-one and onto are too involved to be described here.

Neuer Beweis eines Tutte'schen Satzes. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 135–139.

The theorem mentioned in the title gives a necessary and sufficient condition for the existence of a 1-factor in a given finite graph G [the reviewer, J. London Math. Soc. **22** (1947), 107–111; MR **9**, 297]. A simpler condition can be given for the case in which G is bipartite [ibid. **10** (1935), 26–30].

The author shows that the general condition can be deduced from that for the bipartite case with the help of a simple auxiliary theorem about "critical graphs". A critical graph can be characterized as a graph which has

no 1-factor, but which acquires one when any vertex and its incident edges are removed.

W. T. Tutte (Waterloo, Ont.)

Palásti, Ilona 4051

On the connectedness of bichromatic random graphs. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 431–441 (1964).

The author examines the asymptotic behavior of the number of connected bipartite graphs having n and m vertices in the two vertex sets. The edges are chosen at random with one endpoint in each set. When $n=m$, the probability

$$P(n, n, N_c), \qquad N_c = [n \log n + cn]$$

that the graph with N_c edges is connected satisfies

$$\lim_{n\to\infty} P(n, n, N_c) = \exp(-2e^{-c}).$$

An analogous result is obtained when $n \neq m$.

Singularities of n-spheres in $(n+2)$-space.

Yokohama Math. J. **11** (1963), 23–39.

This paper generalizes work of Fox and Milnor [Bull. Amer. Math. Soc. **63** (1957), 406] to obtain the following theorem. Theorem 2: If a collection $\{k_1, \cdots, k_m\}$ of m $(n-1)$-knot types can occur as the collection of singularities of a 1-flat n-sphere in E^{n+2}, then the product $\prod_{i=1}^m k_i$ is cobordant to the trivial knot. Conversely, Theorem B: If $\prod_{i=1}^m k_i$ is cobordant to the trivial knot, then $\{k_1, \cdots, k_m\}$ occurs as the set of singularities of some S^n in E^{n+2}.

Isotopie von Flächen in einfachen Knoten.

Abh. Math. Sem. Univ. Hamburg **27** (1964), 116–123.

Let k be a simple closed polygon in 3-space which is such that the knot type represented is not a companion [cf. H. Schubert, Acta Math. **90** (1953), 131–286; MR **17**, 291], and let g denote its genus. Then among the polyhedral orientable surfaces of genus g that span k there can be found a finite number such that any polyhedral orientable surface of genus g that spans k is isotopic to one of them by a semilinear isotopy that does not move k. It is conjectured that the condition that k not be a companion is necessary (because of the existence of cable-braids). The proof of the theorem is accomplished by means of the Haken-Schubert machine [W. Haken, ibid. **105** (1961), 245–375; MR **25** #4519a; H. Schubert, Math. Z. **76** (1961), 116–148; MR **25** #4519b].

P. Dedecker (Rhode-St.-Genèse)

Brown, R. 4055

On Künneth suspensions.

Proc. Cambridge Philos. Soc. **60** (1964), 713–720.

Let A, A', B, B' be FD-complexes and Y a css-complex. Let N denote a normalization functor. The author shows (Theorem 1) that a css-homotopy equivalence $\lambda_1: A^Y \to A'$ is determined by a Künneth isomorphism of type $(Y, NA; NA')$. Let $\lambda_2: B^Y \to B'$ be that for the Künneth isomorphism of type $(Y, NB; NB')$. Denoting the set of cohomology operations of type (NA, NB) by $\mathrm{Op}(NA, NB)$, he defined a Künneth suspension κ: $\mathrm{Op}(NA, NB) \to \mathrm{Op}(NA', NB')$ [Proc. London Math. Soc. (3) **14** (1964), 545–565; MR **29** #604]. The main theorem (Theorem 4) says that a natural function of css-homotopy classes $\beta: [A, B] \to [A^Y, B^Y]$ is reduced to κ by canonical isomorphisms $\Phi: [A, B] \to \mathrm{Op}(NA, NB)$ and $\Phi \cdot (\lambda_1^*)^{-1} \cdot \lambda_2^*$: $[A^Y, B^Y] \to \mathrm{Op}(NA', NB')$. When Y is finite-dimensional and X is a connected css-complex, the results are used to determine the homotopy type of X^Y by induction on the Postnikov system of X. As examples, he obtains another proof for some of M. G. Barratt's results [ibid. (3) **5** (1955), 71–106; MR **17**, 290; ibid. (3) **5** (1955), 285–329; MR **17**, 395]: $\pi_{r-1}(X^Y) = Z_2$, $\pi_r(X^Y) \approx Z_4$, where $X = S^p \cup_2 e^{p+1}$ $(p>2)$, $Y = S^{p-r} \cup_2 e^{p-r+1}$.

Rutter, J. W. 4056

Relative cohomology operations.

Quart. J. Math. Oxford Ser. (2) **15** (1964), 77–88.

A relative cohomology functor Γ is a functor from the category of c.s.s. pairs with base point and c.s.s. maps to the category of Abelian groups and set-theoretic maps, having the following form: Let $\{r_i, G_i\}$, $\{s_j, G_j'\}$, $\{t_k, G_k''\}$ be finite sets of pairs, each pair consisting of a positive integer and an Abelian group. Then

$$\Gamma(X, A) = \prod H^{r_i}(X, G_i) \times \prod H^{s_j}(X, A, G_j') \times \prod H^{t_k}(A, G_k'').$$

A relative cohomology operation is a natural transformation of relative cohomology functors.

The author proves that every relative cohomology operation can be expressed in terms of absolute operations plus a few simple operations which are intrinsically relative, such as the coboundary in the sequence of a pair. The proof proceeds via Eilenberg-MacLane spaces.

Hardie, K. A. 4057

On the Hopf-Toda invariant.

Trans. Amer. Math. Soc. **112** (1964), 43–54.

Let S_r^n denote the rn-skeleton of the reduced product complex S_∞^n of the n-sphere S^n. The author discusses a homomorphism

$$H: \pi_i(S_{r-1}^n, S_{r-2}^n) \to \pi_{i+1}(S^{rn})$$

which is equivalent to a special case of the relative "Hopf homomorphism" of H. Toda [J. Inst. Polytech. Osaka City Univ. Ser. A **7** (1956), 103–145; MR **19**, 1188], and uses it to establish various interesting facts about the unstable homotopy groups of the spheres.

These computations independently confirm and slightly extend the results of Toda on the subject [see *Composition methods in homotopy groups of spheres*, Princeton Univ.

Press, Princeton, N.J., 1962; MR 26 #777]. The explicit computations are as follows: let p be an odd prime, and write $[r, n]$ for the p primary component of $\pi_r(S^n)$. Then

(a) $[2t(p-1)+2m-s, 2m+1] = 0$

$$(m \geqq 1, 1 \leqq t \leqq p, 2 \leqq s \leqq 2p-3);$$

(b) (i) $[2t(p-1)+2m-1, 2m+1] = Z_p$

$$(1 \leqq t \leqq p-1, 1 \leqq m \leqq t-1);$$

(ii) $[2t(p-1)+2m-1, 2m+1] = 0$

$$(1 \leqq t \leqq p-1, m \geqq t);$$

(iii) $[2p(p-1)+1, 3] = Z_p$;

(iv) $[2p(p-1)+2m-1, 2m+1] = Z_{p^2}$ or Z_p+Z_p

$$(2 \leqq m \leqq p-1)$$

$$= Z_p \quad (m \geqq p);$$

(c) (i) $[2t(p-1)+2m, 2m+1] = Z_p$

$$(1 \leqq t \leqq p-1, m \geqq 1);$$

(ii) $[2p(p-1)+2m, 2m+1] = Z_{p^2} \quad (m \geqq 2)$;

(iii) $[2p(p-1)+2, 3] = Z_p$.

Hudson, J. F. P.; Zeeman, E. C. 4063

On regular neighbourhoods.

Proc. London Math. Soc. (3) **14** (1964), 719–745.

This paper presents more general and streamlined versions of many of J. H. C. Whitehead's theorems [same Proc. (2) **45** (1939), 243–327]. Where Whitehead assumed a space with a specific triangulation, the authors here assume a family of piecewise related triangulations, where Whitehead proved uniqueness of regular neighborhoods up to a piecewise linear homeomorphism, the present authors prove, with appropriate hypotheses, uniqueness up to an ambient isotopy, and where Whitehead considered absolute neighborhoods, these authors consider a relative version of a regular neighborhood. The definition of the relative neighborhood is as follows. Assume X, Y, N compact subpolyhedra of a polyhedral m-manifold M. N is a regular neighborhood of X mod Y in M if (1) N is an m-manifold, (2) N is a (topological) neighborhood of $X-Y$, (3) $N \cap Y = \dot N \cap Y = \overline{X-Y} \cap Y$, (4) N collapses to $\overline{X-Y}$.

The main theorems proved are an existence theorem for relative neighborhoods and two uniqueness theorems, the second referring to neighborhoods which meet the boundary of M in a required manner.

There are eleven very interesting corollaries proved, not all of which require the relative neighborhood theorem. For example (Corollary 4), let X be a spine of M, let N be a regular neighborhood of X in $\mathring M$; then $\overline{M-N} \cong \dot M \times I$.

Using their stronger form of Whitehead's uniqueness theorem the authors prove Corollary 7: Suppose M is without boundary, then two compact polyhedra in M are of the same type if and only if their regular neighborhoods are ambient isotopic.

The authors ask several questions, some of which are well known, some of which have been partially or fully answered by now, and some of which are novel. Question 3 in particular has been answered in the affirmative by the reviewer and J. Levine independently, provided the boundary sphere pair is unknotted. One proof of an affirmative answer to question 3 in the classical case is attributed to B. Mazur. This is incorrect: the proof in question is due to R. Fox. Question 4 has been answered negatively by Hirsch and the reviewer, and J. Stallings and J. Levine. *L. Neuwirth* (Princeton, N.J.)

Some properties of foliations.

Ann. Inst. Fourier (Grenoble) **14** (1964), *fasc.* 1, 31–35.

Let M be a manifold with a C^2 foliation of co-dimension 1. A nonempty compact subset C of M is said to be minimal if, for any $x \in C$, the closure of the leaf L_x containing x is C itself. A. J. Schwartz's theorem on minimal sets for the case of dim $M = 2$ [Amer. J. Math. **85** (1963), 453–458; errata, ibid. **85** (1963), 753; MR **27** #5003] is generalized as follows: If C is minimal and if, for every $x \in C$, the first Betti number of L_x is zero, then either $C = M$ or C is a compact leaf. The author also gives another result. Let $M \to B$ be a C^2 fiber space with fiber S^1, where B is an $(n-1)$-manifold with abelian $\pi_1(B)$. If the foliation of M is transversal to the fibers, then any minimal set is either M or a compact leaf. *K.-T. Chen* (New Brunswick, N.J.)

A duality in integral geometry; some generalizations of the Radon transform.

Bull. Amer. Math. Soc. **70** (1964), 435–446.

The author begins with the following reciprocity formula due to F. John. Let f be a compactly supported C^∞ function on $\mathbf{R}^{2n+1}$. Then

$$(1) \qquad f(x) = \frac{1}{2}(2\pi i)^{-2n}\Delta^n\left(\int_\Omega J(\omega, \langle\omega, x\rangle)\, d\omega\right),$$

where $\Delta = \sum_{i=1}^{2n+1} \partial^2/\partial x_i^2$, Ω is the $2n$-sphere with surface element $d\omega$, and $J\langle\omega, r\rangle = \int_{\{y:\langle y,\omega\rangle = r\}} f(y)\, dy$. With the duality aspect of (1) in mind, the following situation is considered. Let X be a manifold, G a transitive Lie group acting on X, and let Ξ be a family of subsets of X which G permutes and which has the structure of a manifold (above, $X = \mathbf{R}^{2n+1}$, G is the Euclidean group, and Ξ is the set of hyperplanes in $\mathbf{R}^{2n+1}$). The space Ξ is called the dual of X. Given $x \in X$, set $\check{x} = \{\xi \in \Xi : x \in \xi\}$. It is assumed that each ξ and $\check{x}$ have measures μ and ν, both preserved by G; denote by $D(X)$, $D(\Xi)$ the algebra of G-invariant differential operators on X, Ξ, respectively. Define $\hat{f}(\xi) = \int_{x\in\xi} f(x)\, d\mu(x)$, $\check{g}(x) = \int_{\xi\in\check{x}} g(\xi)\, d\nu(\xi)$. The author considers the following two problems: (A) Describe the mappings $f \to \hat{f}$, $g \to \check{g}$, $f \to (\hat{f})^\vee$, etc.; (B) Do there exist maps $D \to \hat{D}$ of $D(X)$ to $D(\Xi)$ and $E \to \check{E}$ of $D(\Xi)$ to $D(X)$ such that $(Df)^\wedge = \hat{D}\hat{f}$, $(Eg)^\vee = \check{E}\check{g}$?

Example: Let X be a two-point homogeneous space (that is, a compact Riemannian manifold with group of isometries G which permutes pairs of points at equal distance). Denote by δ the diameter of X and, for $x \in X$, let $A_x = \{y \in X:$ distance $(x, y) = \delta\}$ be the antipodal manifold. Let A_x be the family of antipodal manifolds ($x \neq y$ implies $A_x \neq A_y$) with the Riemannian structure such that $x \to A_x$ is an isometry. Then $f \to \hat{f}$ is one-to-one and $(\Delta f)^\wedge = \hat{\Delta}\hat{f}$, where Δ, $\hat{\Delta}$ are the Laplacians on X, Ξ. Furthermore, with one exception, $f = P(\Delta)(\hat{f})^\vee$ for a suitable polynomial P.

This article is valuable to the non-expert, as it is expository and clearly written. *Phillip A. Griffiths* (Berkeley, Calif.)

Schwartz, Jacob T. 4069

Generalizing the Lusternik-Schnirelman theory of critical points.

Comm. Pure Appl. Math. **17** (1964), 307–315.

Results in the calculus of variations in the large are, generally speaking, of two sorts. On the one hand there are results of the Morse theory type which make strong a priori assumptions on the nature of the critical locus of a smooth function f on a manifold M (i.e., non-degeneracy of critical points or of critical submanifolds) and conclude rather precise facts (e.g., the Morse inequalities) about the relation of the critical locus of f and the homology, homotopy, or even diffeomorphism type of M. On the other hand there are results of the Lusternik-Schnirelman type, which make no a priori assumption on the nature of the critical locus of f and conclude relations between the critical locus of f and the category of M (i.e., the least integer k for which there exists a covering of M by k closed sets, each contractible in M). The reviewer [Topology **2** (1963), 299–340; MR **28** #1633] and the reviewer and S. Smale [Bull. Amer. Math. Soc. **70** (1964), 165–172; MR **28** #1634] indicated how to extend Morse theory from the classical case, where f was a proper function on a finite-dimensional manifold, to the case where M is a C^2 complete Riemannian manifold modeled on a separable Hilbert space and f is a C^2 function satisfying the following condition: If S is a closed subset of M on which f is bounded, but on which $\|\nabla f\|$ is not bounded away from zero, then there is a critical point of f in the closure of S. In the present paper the author develops a Lusternik-Schnirelman theory under the same hypotheses. In particular, for example, he proves that if such an f is bounded below, then it has at least cat(M) critical points. In addition, the author gives as an application the following theorem which he attributes to Serre: If N is a compact simply connected Riemannian manifold and p and q are

points of M, then p and q are connected by geodesics of infinitely many distinct lengths.

Über holomorphe und meromorphe Abbildungen gewisser kompakter komplexer Mannigfaltigkeiten.

Arch. Math. **15** (1964), 222–231.

The author proves the following. Let X_1 and X_2 be compact Kähler manifolds with negative first Chern class, and let $\alpha_1: X_1 \to X_2$ and $\alpha_2: X_2 \to X_1$ be meromorphic maps. Then α_1 and α_2 are in fact biholomorphic maps. This theorem implies that every meromorphic map of the complete intersection $V_n^{(a_1,\cdots,a_r)}$ onto itself is biholomorphic, provided $\sum a_i > n+r+1$.

Several more conditions are stated in order that a meromorphic or a surjective holomorphic map be biholomorphic. *H. Röhrl* (La Jolla, Calif.)

Narasimhan, M. S.; Seshadri, C. S. 4072

Holomorphic vector bundles on a compact Riemann surface.

Math. Ann. **155** (1964), 69–80.

The authors prove that the set M of equivalence classes of holomorphic vector bundles over a compact Riemann surface X of genus $g \geq 2$ that arises from an n-dimensional irreducible unitary representation of $\pi_1(X)$ forms a complex manifold. For this purpose, consider the kernel K of the homomorphism $U(n)^{2g} \to SU(n)$ that sends $(A_1, B_1, \cdots, A_g, B_g)$ into $A_1B_1A_1^{-1}B_1^{-1}\cdots A_gB_gA_g^{-1}B_g^{-1}$. The set of regular points of this real-analytic variety K corresponds precisely to the set M_0 of irreducible unitary representations of $\pi_1(X)$, whence M_0 can be given the structure of a real-analytic manifold. Since two holomorphic vector bundles over a compact complex manifold X that arise from irreducible unitary representations of $\pi_1(X)$ are isomorphic if and only if the representations are equivalent, M can be written as the orbit space of M_0 under the obvious free action of PU(n). Hence M itself can be given the structure of a real-analytic manifold. The tangent space of M at $m \in M$ can be identified canonically with $H^1(\pi_1(X), \mathrm{ad}\,\rho)$, where ρ is a unitary representations in the class m. Since for $P(\rho)$, the holomorphic principal bundle determined by ρ, the natural homomorphism $H^1(\pi_1(X), \mathrm{ad}\,\rho) \to H^1(X, \mathrm{Ad}\,P(\rho))$ is an isomorphism of real vector spaces and since $H^1(X, \mathrm{Ad}\,P(\rho))$ has a natural structure of a complex vector space, M acquires an almost complex structure. This almost complex structure in turn can be shown to be integrable.

Erdős, P.; Neveu, J.; Rényi, A. 4075

An elementary inequality between the probabilities of events.

Math. Scand. **12** (1963), 99–104.

Let n be a positive integer and let $\alpha \in (0, 1)$. Denote by $\varepsilon_n(\alpha)$ the least real number ε satisfying the inequality

$$\sum_{i=1}^{n} P(A_i) - n\alpha \leq \varepsilon$$

for any sequence of random events A_i $(i = 1, \cdots, n)$ with the condition $P(A_iA_j) \leq \alpha^2$, $1 \leq i < j \leq n$. Two equivalent definitions of $\varepsilon_n(\alpha)$ are given, and its exact value is obtained: If ν is the largest integer such that $\nu(\nu-1) \leq n(n-1)\alpha^2$, then

$$\varepsilon_n(\alpha) = \tfrac{1}{2}(1-\alpha) + (n\alpha - \nu)[(n-1)\alpha - \nu]/(2\nu).$$

The second term is zero if $n\alpha$ or $(n-1)\alpha$ is an integer: for $n \to \infty$ it is of the order $1/n$.

For any n and α there exists a sequence A_i^* $(i = 1, \cdots, n)$ such that

$$P(A_i^*) = \alpha + \varepsilon_n(\alpha)/n, \qquad P(A_i^*A_j^*) = \alpha^2 \qquad (i \neq j).$$

An example of such an extremal sequence of random events is constructed for $\alpha = \frac{1}{2}$, $n \equiv 3 \bmod 4$ by means of the theory of quadratic residues.

A particular case of this problem was investigated independently by S. Zubrzycki [Studia Math. **14** (1955), 232–242; MR **16**, 839]. *J. Kubilius* (Vilnius)

The limiting joint distribution of terms of variational series. (Chinese. English summary)
Acta Sci. Natur. Univ. Pekinensis **10** (1964), 211–226.

Authors' summary: "The following results for limiting joint distribution of variational series are obtained. (1) The limiting joint distribution of m middle terms whose limit ranks are $\lambda_1, \cdots, \lambda_m$, $0 \le \lambda_1 < \cdots < \lambda_m \le 1$, exists if and only if the limit distribution of every term exists. Therefore, by Smirnov's results, the number of types of the limiting joint distribution law of the m middle terms $\xi_{k_1}^{(n)}, \cdots, \xi_{k_m}^{(n)}$ which satisfy the regularity conditions

$$\lim_{n\to\infty} \sqrt{n}\left(\frac{k_i}{n} - \lambda_i\right) = t_i, \qquad |t_i| < \infty, \quad i = 1, \cdots, m,$$
$$0 < \lambda_1 < \cdots < \lambda_m < 1,$$

is 4^m. The fields of attraction of those types of law are obtained. (2) The limiting joint distribution of s left (or right) marginal terms of constant ranks exists if and only if the limit of every term exists. The limiting joint distribution of marginal terms of constant ranks exists if and only if: (i) The limiting distribution of one left and one right marginal term both exist; (ii) the limiting joint distribution of the m middle terms exists. If the m middle terms satisfy regularity conditions, then, by Smirnov's and Gnedenko's results, the number of types of limit law is $9\cdot 4^m$. The fields of attraction of those laws are also obtained."

Csáki, E.; Vincze, I. 4078
On some distributions connected with the arcsine law. (Russian summary)
Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 281–291 (1964).

Several results extending those of the reviewer and Feller, and generalized by E. S. Andersen, are given. The combinatorial formulae are obtained by one-to-one correspondence, from which asymptotic ones are computed. For instance, let s_i, $i = 0, 1, 2, \cdots$, be the successive sums in the coin-tossing game with stakes ± 1, $s_0 = 0$, and let $2\gamma_{2n}^{(2k)}$ denote the number of indices i ($i = 1, \cdots, 2n$) for which either $s_i > 2k$ or $s_i = 2k$ but $s_{i-1} = 2k+1$, where k is a non-negative integer; then

$$P(\gamma_{2n}^{(2k)} = g) = \frac{1}{2^{2n}}\binom{2g}{g}\binom{2n-2g}{n-g+k}, \quad g = 1, 2, \cdots, n-k,$$

$$P(\gamma_{2n}^{(2k)} = 0) = \frac{1}{2^{2n}}\sum_{j=-k}^{k}\binom{2n}{n+j}.$$

Linearkombinationen zufälliger Grössen und ihre gemeinsame Verteilung.
Math. Z. **84** (1964), 403–414.

If $\mathbf{x}$ is a random vector, $\mathbf{t}$ a constant vector and T a set of vectors $\mathbf{t}$ in R^n, denote by μ the probability distribution in R^n of $\mathbf{x}$ and by $\mu_{\mathbf{x}'\mathbf{t}}$ the probability distribution in R^1 of $\mathbf{x}'\mathbf{t}$. The following two problems are treated in the paper. (1) When does there correspond a distribution μ to arbitrarily given distributions $\mu_{\mathbf{x}'\mathbf{t}}$ for all $\mathbf{t} \in T$? It is shown that such a distribution μ always exists if and only if the vectors in T are linearly independent. (2) When is μ uniquely determined, given $\mu_{\mathbf{x}'\mathbf{t}}$ for all $\mathbf{t} \in T$? Cramér and Wold have proved the uniqueness of μ in the case $T = R^n$ [J. London Math. Soc. **11** (1936), 290–294]. If μ is known to belong to a certain class of distributions, this condition may be relaxed. The author studies the two cases where μ is purely discontinuous and μ has an analytic characteristic function, and gives conditions on T to ensure the uniqueness of μ. *C. G. Esseen* (Stockholm)

Krickeberg, Klaus 4080
Wahrscheinlichkeitsoperatoren von Verteilungen in Vektorräumen.
Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 441–452. *Publ. House Czech. Acad. Sci., Prague,* 1964.

The author develops the concept of the probability operator corresponding to a probability distribution in a topological linear space. Such operators can play the role played by characteristic functions in finite-dimensional spaces, and have analogous properties, e.g., the theorems of uniqueness, continuity and convolution are valid for them. Application: a simpler proof of Prohorov's theorem on weak convergence to Brownian motion.

On analogies between two classes of probability distributions: The class of infinitely decomposable distributions and the class of self-decomposable distributions.
Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 461–465. *Publ. House Czech. Acad. Sci., Prague,* 1964.

The class $\mathscr{L}$ is the class of limit distributions of the sum $(1/B_n)\sum_1^n \xi_k - A_n$ of independent random variables ξ_k, where A_n and $B_n > 0$ are constants and ξ_k/B_n are uniformly asymptotically negligible. $\mathscr{L}$ is characterized as the class of convolutions of a finite number of distributions from the class $\mathscr{G}$ of some special distributions and their weak limits [the author, Studia Math. **21** (1961/62), 245–252; MR **26** #1916]. The author, in the present paper, announces that the class $\mathscr{G}$ is, in a certain sense, the smallest class with the property that characterizes the class $\mathscr{L}$ in the above described sense. Also he claims that the same type of relation is true between the class of Poisson distributions and the class of all infinitely divisible distributions. He also observes the isomorphism between the class of infinitely divisible distributions and its subclass $\mathscr{L}$. These results have been proved by the author [ibid. **22** (1962/63), 197–209; MR **26** #4386].

Lukacs, Eugene 4082
A linear mapping of the space of distribution functions onto a set of bounded continuous functions.
Z. Wahrscheinlichkeitstheorie und Verw. Gebiete **3**, 1–6 (1964).

"The great usefulness of characteristic functions in probability theory is based on three properties which are stated by the uniqueness theorem, the convolution theorem and the continuity theorem."

The author considers the linear mapping $\alpha(s; F)$ of the space of distribution functions F onto a space of continuous, uniformly bounded functions of the real variable s. It is shown that the necessary and sufficient condition for $\alpha(s; F)$ to have the three above-mentioned properties is that

$$\alpha(s; F) = \int_{-\infty}^{\infty} e^{ixA(s)}\, dF(x),$$

where $A(s)$ is a continuous real-valued function such that $|A(s)|$ assumes all non-negative real values. Thus $\alpha(s; F)$ is almost a characteristic function. This generalizes an earlier result of the author where integral transforms of distribution functions were studied [Proc. Amer. Math. Soc. **3** (1952), 508–510; MR **13**, 937]. If, in addition, $\alpha(s; F)$ maps every degenerate distribution function onto a non-negative definite function, then $A(s) = Cs$, where C is a constant.

Pfanzagl, J. 4083

On the topological structure of some ordered families of distributions.

Ann. Math. Statist. **35** (1964), 1216–1228.

A new definition of order for families of distributions, including as a special case monotone likelihood ratio families, is investigated. For such ordered families convergence in the weak sense is equivalent to convergence of the measures on all subsets. Such families are, in general, homeomorphic to dominated families of distributions indexed by a real parameter.

Barndorff-Nielsen, O. 4085

Characteristic subsequences and limit laws for weighted means.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), pp. 17–27. *Publ. House Czech. Acad. Sci., Prague*, 1964.

From the author's summary: "In proving limit theorems for sequences $\{Z_n\}$ of random variables, it is a standard method to choose a suitable subsequence, $\{Z_{n_k}\}$ of $\{Z_n\}$, verify that if (and only if) the theorem holds for the subsequence then it holds for $\{Z_n\}$ (so that the subsequence is in a sense 'characteristic' for $\{Z_n\}$ with respect to the convergence property in question) and finally prove the theorem for $\{Z_{n_k}\}$. By analyzing applications of this method we have been able to establish some elementary lemmas of analytic nature, which may be used to sharpen well-known limit theorems in the theory of probability. Section 2 contains the proofs of some of the lemmas mentioned above. In Section 3 we derive strong laws of large numbers for weighted means of random variables, which are uniformly bounded or have uniformly bounded pth moments $(p > 1)$. Theorem 4.1 is an assertion about convergence in distribution for weighted means of indicators (i.e., random variables assuming only the values 0 and 1). By means of this theorem it is possible to obtain certain generalizations of the arcsine law."

Proof of existence and uniqueness of a stationary ergodic distribution in a problem on flow control. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **34** (1964), 535–540.

Independent random variables X_t, $t = 0, 1, 2, \cdots$, have common density proportional to $x^{a-1}e^{-bx}$, $x > 0$, and zero elsewhere. The process $\{Z_t\}$ is defined inductively by $Z_{t+1} = \max\{0, \min(X_t + Z_t - \alpha, \beta)\}$, α, β positive constants. The limiting distribution of Z_t is found in the case $\alpha > \beta$.

J. G. Wendel (Ann Arbor, Mich.)

Dwass, Meyer; Karlin, Samuel 4087

Conditioned limit theorems.

Ann. Math. Statist. **34** (1963), 1147–1167.

Suppose that $\{X_n\}$ is a Markov process on the line (with stationary transition probabilities) such that for some sequence of constants $a_n > 0$, $\{X_{[nt]}/a_n\}$ converges as $n \to \infty$ to a limiting process. Suppose also that the recurrent event $E_n = \{X_n = 0\}$ is persistent and not periodic. Then it is of considerable interest to study the limiting behavior of various functionals of $\{X_n\}$, given that E_n occurs, and that is the object of this paper.

Two main types of processes $\{X_n\}$ are considered. The first is sums of independent, integer-valued random variables; they are assumed to belong to the domain of a symmetric stable law of index $1 < \alpha \le 2$, so that the limiting process is a stable one. The other type is a Markov chain which has "local" character, that is, transitions are to neighboring integers only (random walk or birth-and-death). In this case the limiting process must be a diffusion of the "Bessel" type, of which (aside from the Wiener process itself) the best-known example is the radial component of two-dimensional Brownian motion. These things have been discussed by the reviewer [J. Math. Mech. **11** (1962), 749–772; MR **26** #5629; Trans. Amer. Math. Soc. **104** (1962), 62–78; MR **25** #1575] and by C. Stone [Illinois J. Math. **7** (1963), 638–660; MR **28** #1663]. {Incidentally, the reference to the reviewer's paper in Ann. Math. Statist. **33** (1962), 685–696 [MR **25** #632] in the first paragraph of the paper under review ought to have been to the first of the articles cited above.}

The method of attack is to seek relations between the distribution of a functional for the conditioned process and of the same functional for the unconditioned process. Consider, for instance, the number of times $X_m = 0$, $m \le n$, say N_n. The value of N_n for the unconditioned process is equal to N_T, where T is the time of the last zero prior to n.

Thus it is possible to write an equation relating the conditional distributions of N_m, given E_m, to the laws of T and N_n. In the cases studied it is possible to pass to the limit $n\to\infty$ and obtain an equation involving the (known) limit laws of N_n and T, which can be solved by taking Laplace transforms. The result is a statement that if the conditioned limiting law exists, it must have a certain form; the existence generally needs independent verification.

Many results, both for stable and "Bessel" processes, are obtained in more or less this way. The main functionals considered are one- and two-sided maxima, occupation time of state 0, and occupation time of half-lines. In addition to determination of the necessary form of the conditional limiting laws, proofs of existence are given in some cases, but the results here are far from complete. Applications and examples are pointed out, and some open questions are mentioned in a final section.

In the reviewer's opinion, this is a very interesting paper which treats important new questions and should stimulate much further work.

J. W. Lamperti (Hanover, N.H.)

Guiaşu, Silviu 4088

Sur la répartition asymptotique pour les suites aléatoires de variables aléatoires.

C. R. Acad. Sci. Paris **259** (1964), 973–976.

This paper is a research announcement of results stated without proof. Proofs are to appear [Rev. Roumaine Math. Pures Appl. Bucarest **10** (1965)]. The author is interested in limit laws (not necessarily central limit) for sequences of random variables when random normalization is used, and his stated theorems generalize results of Anscombe, Rényi, Blum, Hanson, Rosenblatt, Mogyoródi, and himself.

Let $\{Y_n, n\geq 1\}$ be a random variable sequence, $\{N_r, r\geq 1\}$ a positive integer-valued random variable sequence, $\{\omega_n, n\geq 1\}$ a positive real number sequence, $\{n_r, r\geq 1\}$ an increasing integer sequence with limit infinity, θ a real number and $F(\cdot)$ a distribution function. The author states conditions under which

$$\lim_{r\to\infty} \text{in prob } N_r/n_r = \lambda$$

and

$$\lim_{n\to\infty} P(\{Y_n-\theta < a\omega_n\}) = F(a)$$

imply

$$\lim_{r\to\infty} P(\{Y_{N_r}-\theta < a\omega_{N_r}\}) = F(a).$$

Some of the stated conditions are in terms of the conditional distributions of $\{Y_n, n\geq 1\}$, given the values of additional random variables $\{\nu_n, n\geq 1\}$, thus giving an added degree of generality. *R. H. Farrell* (Ithaca, N.Y.)

Bretagnolle, Jean; Dacunha-Castelle, Didier 4089

Convergence de la n-ième convoluée d'une loi de probabilité.

C. R. Acad. Sci. Paris **258** (1964), 4910–4913.

The main theorem of the paper is the following. Let $X_1, X_2, \cdots$ be a sequence of independent non-lattice distributed random variables with the characteristic function $\varphi(t)$. (D_α) is the hypothesis that there exist constants B_n such that

$$(\varphi(B_n^{-1}t))^n \to \exp(-|t|^\alpha), \qquad n\to\infty,\ 0<\alpha\leq 2,$$

i.e., the random variables belong to the domain of attraction of a symmetric stable distribution with exponent α. By (B) is meant the weak convergence of measures for all continuous functions with compact support. If F^{*n} is the distribution function of $\sum_1^n X_i$, then under (D_α),

$$B_nF^{*n}(dx) \xrightarrow{(B)} \Gamma(\alpha^{-1})(\pi\alpha)^{-1}dx, \qquad n\to\infty,$$

where dx is the Lebesgue measure. The method of proof is indicated. This theorem supplements a result due to Gnedenko [Gnedenko and Kolmogorov, *Limit distributions for sums of independent random variables*, Addison-Wesley, Cambridge, Mass., 1954; MR **16**, 52] and generalizes a theorem by Shepp [#4090 below] where the case $\alpha=2$ is treated. *C. G. Esseen* (Stockholm)

Shepp, L. A. 4090

A local limit theorem.

Ann. Math. Statist. **35** (1964), 419–423.

The results of this paper are related to those of Gnedenko concerning a local limit theorem for a sum of independent random variables [Gnedenko and Kolmogorov, *Limit distributions for sums of independent random variables*, Addison-Wesley, Cambridge, Mass., 1954; MR **16**, 52]. Let $X_1, X_2, \cdots$ be a sequence of identically distributed independent random variables with $E(X_1)=0$, $E(X_1^2)=\sigma^2<\infty$, and let $g(y)$ be a continuous function with compact support. If $H_n(y)=(2\pi n\sigma^2)^{1/2}F_n(y)$, where $F_n(y)$ is the distribution function of $\sum_1^n X_i$, and if X_1 does not have a lattice distribution, then

$$\int g(y)H_n(dy)\to\int g(y)\,dy, \qquad n\to\infty.$$

In the lattice case, let the probability mass be concentrated to $\alpha+k\beta$, $k=0, \pm 1, \pm 2, \cdots$, where β is maximal and chosen equal to one. If $\alpha=0$, then

$$(1)\qquad \int g(y)H_n(dy)\to\int g(y)\nu(dy), \qquad n\to\infty,$$

where the measure $\nu[a,b]$ is the number of integers in $[a,b]$. If α is irrational, then

$$\int g(y)H_n(dy)\to\int g(y)\,dy, \qquad n\to\infty,$$

in $(C,1)$-mean. There is a slight misstatement of the conditions under which (1) is valid.

C. G. Esseen (Stockholm)

Shepp, L. A. 4091

A limit law concerning moving averages.

Ann. Math. Statist. **35** (1964), 424–428.

Let $X_1, X_2, \cdots$ be mutually independent, identically distributed random variables with $E(e^{tX})<\infty$ for some $t>0$. The paper deals with the determination of $T=\limsup_{n\to\infty} T_n$, where $T_n=(S_{n+f(n)}-S_n)/f(n)$ and $f(n)$ is a positive integer-valued nondecreasing function, $n=1, 2, \cdots$. Then T is constant a.e. It is shown that the value of T is closely related to the radius of convergence of the

series $\sum x^{f(n)}$. A theorem of Chernoff [same Ann. 23 (1952), 493–507; MR 15, 241] on "tail" probabilities is essential for the proofs. Application is made to success runs.
C. G. Esseen (Stockholm)

Baklan, V. V. 4092

On the existence of solutions of stochastic equations in Hilbert space. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1963**, 1299–1303.

Let A be a set and $\nu(d\alpha)$, $\alpha \in A$, a measure on Borel subsets of A. Further, let $W(d\alpha \times dt)$ be a Wiener measure on $A \times [t_0, T]$, i.e., a Gaussian random measure with zero mean, values of which on disjoint sets are independent. It is supposed that $EW^2(d\alpha \times ds) = \nu(d\alpha)\, ds$. The author considers the equation

$$(1)\quad \xi(t) = \Gamma_\tau^t \xi(\tau) + \int_\tau^t \Gamma_s^t a[s, \xi(s)]\, ds + \int_\tau^t \int_A \Gamma_s^t b[s, \alpha, \xi(s)] W(d\alpha \times ds),$$

where Γ_s^t, $a[s, \cdot]$, $b[s, \alpha, \cdot]$ are families of operators in a Hilbert space H and the following holds for $\varphi \in H$, $\tau \leq s \leq t$: $\Gamma_\tau^t\varphi = \Gamma_s^t\Gamma_\tau^s\varphi$, $\Gamma_t^t\varphi = \varphi$. When $\Gamma_s^t a[s, \varphi]$ and $\Gamma_s^t b[s, \alpha, \varphi]$ are uniformly Hölder-continuous in φ and, for a positive integer j, $\int_\tau^T E\|\Gamma_\tau^t \xi(\tau)\|^{2j}\, dt < \infty$, then equation (1) has a unique solution $\xi(t)$, independent of $W(d\alpha \times ds)$ for $s > t$, satisfying $\int_\tau^T E\|\xi(t)\|^{2j}\, dt < \infty$. The proof of this theorem is based on an inequality for moments of Wiener integrals given in the paper.
Petr Mandl (Prague)

Ikeda, Nobuyuki; Ueno, Tadasi [Ueno, Tadashi]; Tanaka, Hiroshi; Satô, Kenkichi 4093

A boundary-value problem for multi-dimensional diffusion processes. (Japanese)

Sûgaku **12** (1961/62), 37–53.

Consider a bounded domain D in R^n having sufficiently smooth boundary ∂D. A Feller semi-group on $C(\bar{D})$ is a semi-group $\{T_t; t \geq 0\}$ of non-negative, linear contraction operators T_t on the Banach space $C(\bar{D})$ of all continuous functions on $\bar{D}$. In this expository note, the authors first consider the following problem. Find all possible Feller semi-groups on $C(\bar{D})$ whose infinitesimal generator $\mathfrak{G}$ satisfies

$$(*)\qquad \mathfrak{G}u(x) = \tfrac{1}{2}\bar{\Delta}u(x) \quad \text{for } x \in D, \qquad u \in \mathfrak{D}(\mathfrak{G}).$$

Here $\mathfrak{D}(\mathfrak{G})$ denotes the domain of definition of $\mathfrak{G}$ and $\bar{\Delta}$ denotes the closure of the Laplacian Δ in $C(\bar{D})$.

The authors first introduce the boundary conditions of A. D. Ventcel' which must be satisfied by functions in $C^2(\bar{D}) \cap \mathfrak{D}(\mathfrak{G})$ for such semi-groups [Teor. Verojatnost. i Primenen. 4 (1959), 172–185; MR 21 #5246]. The authors then describe the method of constructing semi-groups which satisfy (*) as well as Ventcel''s boundary conditions. This method was first obtained by T. Ueno for more general second-order elliptic operators on D and the results were announced by him in Proc. Japan Acad. 36 (1960), 533–538 [MR 26 #1926]. The authors then discuss "the Markov process on the boundary concerning the diffusion" which was introduced by T. Ueno [ibid. 36 (1960), 625–629; MR 26 #1926]. They present the result of K. Sato [ibid. 39 (1963), 69–73; MR 27 #1983] showing that, in the case of a reflecting barrier diffusion, the process on the boundary can be obtained by means of a random time substitution from the diffusion, and that "the local time on the boundary", whose existence was established by K. Sato and H. Tanaka [ibid. 38 (1962), 699–702; MR 26 #5618], can be used as the time change function in this substitution. Next, the authors show that one can construct the sample paths of the diffusion process corresponding to Ventcel''s boundary conditions using the method of stochastic integral equations. This construction is due to N. Ikeda and the result, together with detailed proofs and applications, has been published in Mem. College Sci. Univ. Kyoto Ser. A Math. 33 (1960/61), 367–427 [MR 23 #A4177].

Finally, in the last section of this note, the authors make a few remarks concerning the probabilistic solutions of Dirichlet and Neumann problems for Δ in D, excessive functions and random additive functionals, and general methods of obtaining a new Markov process out of old ones such as killing, random time change, and so on.
Yuji Itô (Providence, R.I.)

Čantladze, T. L. 4094

A stochastic differential equation in Hilbert space. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **33** (1964), 529–534.

Let H be a separable Hilbert space, $a(t, x)$, $b_k(t, x)$ $(k = 1, 2, \cdots)$ functions from $[s, t] \times H$ into H, and let $b_k(t, x)$ be mutually orthogonal. The author examines the stochastic integral equation

$$(1)\quad \xi(t; s, x) = x + \int_s^t a(z, \xi(z))\, dz + \sum_{k=1}^{\infty} \int_s^t b_k(z, \xi(z))\, dw_k(z),$$

where $w_k(t)$ are mutually independent Brownian motion processes. He gives a sufficient condition for the solvability and uniqueness of (1). We denote by $\bar{H}$ the Hilbert space of square integrable random variables with values in H. The paper contains conditions for strong differentiability of $\xi(t; s, x)$ as a function taking $x \in H$ into $\bar{H}$, conditions for the differentiability of $U(s, x) = Eg(\xi(t; s, x))$ and the backward equation

$$-\frac{\partial U}{\partial t} = \delta U(s, x; a(t, x)) + \frac{1}{2}\sum_{k=1}^{\infty} \delta^2 U(s, x; b_k(t, x), b_k(t, x)).$$

Here $\delta U(s, x; y)$ and $\delta^2 U(s, x; y, z)$ are the first and the second differentials of $U(s, x)$. One theorem concerns the absolute continuity of distributions induced by the solutions of two equations of the form (1).

Teilprozesse Poissonscher Prozesse.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 377–403. *Publ. House Czech. Acad. Sci., Prague*, 1964.

Let M be the collection of ordered pairs (t, k) with t real and k in some non-empty set K. Let X be the collection of all subsets x of M such that (i) if p_1 and p_2 are distinct points in x, then they have different first (i.e., t or time) coordinates, and (ii) the collection of t-coordinates of points in x contains no limit points. X is the collection of elementary events x. K may be thought of as a set indexing the various types of events which may occur, and (t, k) in x may be thought of as meaning that if the elementary event x occurs, then the event indexed by k occurs at time t. The author defines a point process as a (stationary) probability measure on a suitable σ-field F of subsets of X.

Let F_A (a sub-σ-field of F) be the collection of all events which are defined in terms of what occurs at time t in A. Think of P_s^x as a conditional probability measure on $F_{[0,s]}$ given $F_{(-\infty,0)}$ evaluated at the point x. Under suitable restrictions the author calls $((P_s^x))$ a chain for a point process.

In special cases the author (i) obtains the existence of a unique chain satisfying certain conditions, (ii) obtains a unique point process with a given chain, and (iii) obtains uniform convergence (as s goes to infinity) of the distribution on $F_{[s,\infty)}$, which is induced by an arbitrary distribution on $F_{(-\infty,0)}$ and a given chain, to the unique stationary distribution on $F_{[s,\infty)}$.

The author's model is both interesting and unusual.

Nisio, Makiko 4100

On the representation of strictly stationary processes. (Japanese)

Sûgaku **13** (1961/62), 58–64.

In Section 1 of this expository note, the author describes without giving details the results of approximating a strictly stationary process, continuous in probability, by so-called polynomial processes. These results were first obtained by N. Wiener [Amer. J. Math. **60** (1938), 897–936] and then reproved by the author. A detailed account of these results has been published by the author [J. Math. Soc. Japan **12** (1960), 207–226; MR **22** #6019]. In Section 2, the results obtained by the author on the so-called canonical representation of strictly stationary processes are presented. These, together with detailed proofs, have appeared [J. Math. Kyoto Univ. **1** (1961/62), 129–146; MR **26** #7020]. Finally, in Section 3, the author considers the case of strictly stationary time series and describes in a slightly rephrased form the results of M. Rosenblatt [J. Math. Mech. **8** (1959), 665–681; MR **22** #5073].

Priestley, M. B. 4101

The spectrum of a continuous process derived from a discrete process.

Biometrika **50** (1963), 517–520.

Let $\{X_n, n=0, \pm 1, \cdots\}$ be a stationary stochastic process. The author shows that the $\{X_n\}$ process can be embedded in a continuous-parameter, stationary process by defining $X_t = X_{i+1}$ if $i \leq t-\varphi < i+1$, where φ is an observation on a random variable distributed uniformly on $[0, 1]$. He also derives an expression for the spectral density of the new process.

Rozanov, Ju. A. 4102

On the stability of solutions of linear problems for stationary processes. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 528–530.

Author's summary: "Let $\xi(t)$ be a stationary process with spectral function $F(\lambda)$, prediction error

$$\sigma^2 = \inf \int |e^{i\lambda s} - \sum_{t \in T} c(t) e^{i\lambda t}|^2 \, dF(\lambda)$$

and let

$$\delta(G)^2 = \inf \int |e^{i\lambda s} - \sum_{t \in T} c(t) e^{i\lambda t}|^2 \, dF_1(\lambda),$$

where $F_1(\lambda) = F(\lambda) + G(\lambda)$, $dG(\lambda) \geq 0$ and $\int dG(\lambda) \leq h^2$. Then $\lim_{h \to 0} \sup_G \delta(G) = \sigma$. Other linear problems similar to the prediction one have solutions with the same properties."

Some problems for stationary processes on a finite interval reducing to integral equations of Wiener-Hopf type. (Russian)

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 605–609. *Publ. House Czech. Acad. Sci., Prague,* 1964.

Let $\xi(t)$ be a stationary process with spectral measure $F(d\lambda)$. There are many statistical problems based on $\xi(t)$ given only on a finite interval $[0, T]$. Such problems are reduced to solving the Wiener-Hopf integral equation

$$(1) \qquad \int_{-\infty}^{\infty} e^{-it\lambda} \varphi(\lambda) F(d\lambda) = A(t), \qquad 0 \leq t \leq T,$$

where $A(t)$ is known, and $\varphi(\lambda)$ is unknown but should belong to the space $L^2(F(d\lambda))$, spanned by $e^{it\lambda}$, $0 \leq t \leq T$.

Linear prediction of $\xi(s)$, $s < 0$ or $s > T$, construction of the least mean-square-error estimates of regression coefficients, and a certain kind of smoothing in automatic regulation are such examples. When $\xi(t)$ is Gaussian, the author also states that for absolute continuity of the probability measure of $\xi(t) + A(t)$, $0 \leq t \leq T$, with respect to that of $\xi(t)$, $0 \leq t \leq T$, it is necessary and sufficient that the solution to (1) exist. *G. Maruyama* (Fukuoka)

Stetigkeitseigenschaften der Realisierungen Gauss'scher zufälliger Felder.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 831–839. *Publ. House Czech. Acad. Sci., Prague,* 1964.

Entsprechend ihrer Bedeutung in der statistischen Turbulenztheorie werden besonders homogene, bzw. homogene und isotrope, zufällige Felder untersucht. Die homogenen, zufälligen Felder stellen eine Verallgemeinerung des Begriffs des stationären zufälligen Prozesses dar. Für sie wird eine Spektraltheorie entwickelt. Sowohl vom theoretischen Standpunkt als auch vom Standpunkt der Anwendungen ist es wichtig, Bedingungen dafür zu kennen, unter welchen die Realisierungen eines zufälligen Feldes mit Wahrscheinlichkeit 1 stetige Funktionen sind, bzw. einer Lipschitzbedingung genügen. In dieser Arbeit werden insbesondere Gauss'sche zufällige Felder in Hinblick auf die Stetigkeitseigenschaften ihrer Realisierungen untersucht. *E. A. Robinson* (Uppsala)

Csáki, Péter; Fischer, János 4106

On the general notion of maximal correlation. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 27–51.

The authors introduce a functional $S(H_1, H_2)$ on pairs of subspaces H_1, H_2 of a Hilbert space, and characterize it by means of $S(H_1, H_2) = \sup\{(x, y) : x$ and y of norm one, $x \in H_1, y \in H_2\}$. In probabilistic contexts subspaces arising naturally consist of square-integrable functions orthogonal to constants and measurable with respect to specified subalgebras of the basic σ-algebra. Then S is called the maximal correlation of the subalgebras. The authors compute it for a number of examples, and prove the interesting Theorem (5.1): If two such subalgebras are generated by random variables ξ, η, respectively, then the maximal correlation equals $\sup(u, v)$, where u and v range over univalent functions of ξ and η, $(u, 1) = (v, 1) = 0$, $\|u\| = \|v\| = 1$. *J. G. Wendel* (Ann Arbor, Mich.)

Lion, Georges 4107

Principe complet du maximum et semi-groupes sous-markoviens.

C. R. Acad. Sci. Paris **258** (1964), 3621–3623.

Let C_K and C_0 be the spaces of real continuous functions with compact support and continuous functions vanishing at infinity, respectively, on a separable locally compact space X. The author considers a positive linear transformation V which maps C_K into C_0. The author first shows that the complete principle of the maximum and the weak principle of the positive maximum are equivalent for such operators. That the first implies the second is due to G. A. Hunt [Illinois J. Math. **1** (1957), 316–369, esp. pp. 351–357; MR **19**, 951]. Assuming that the operator V satisfies these two principles, a family of positive operators $\{V^\lambda; \lambda > 0\}$ on C_0 is constructed satisfying (1) $(I - \lambda V^\lambda) V = V^\lambda$, $\lambda > 0$; (2) $V^\lambda - V^\mu = (\mu - \lambda) V^\lambda V^\mu$, $\lambda, \mu > 0$; (3) $\|\lambda V^\lambda\| \leq 1$, $\lambda > 0$; (4) if $f \in C_K$, then $\|V^\lambda f - Vf\| \to 0$ as $\lambda \to 0$. $V(C_K)$ is not assumed to be dense in C_0. Letting H denote the closure of the range of V^λ, which is independent of λ, it is shown that there is a semi-group of sub-Markovian transition operators $\{P_t : t \geq 0\}$ taking elements of C_0 into Borel measurable functions such that $Vf(x) = \int_0^\infty P_t f(x)\, dt$ for $f \in C_K$, assuming H separates the points of the Alexandroff compactification of X. This result is a generalization of a theorem due to Hunt in which $V(C_K)$ is assumed to be dense in C_0.

Chung, Kai Lai 4108

The general theory of Markov processes according to Doeblin.

Z. Wahrscheinlichkeitstheorie und Verw. Gebiete **2**, 230–254 (1964).

The paper deals with discrete-time Markov chains on a general state space X and transition probability $P(X, E)$. When X is countable only the classification and periodicity properties of states are well known [W. Feller, *An introduction to probability theory and its applications*, Vol. I, Chapter 15, second edition, Wiley, New York, 1957; MR **19**, 466]. Here the analogous problems are treated for general X, and even though Doeblin [Ann. Sci. École Norm. Sup. (3) 57 (1940), 61–111; MR **2**, 3] already gave definitive results for this general case, they are not widely known, perhaps because Doeblin's article was not very clear in many places. The present paper simplifies, cleans up and extends Doeblin's paper. There are too many propositions to give a detailed description of the contents, so that we only state a sample result.

A set C is called closed if the Markov chain cannot leave C once it enters C, i.e., $P(x, C) = 1$ for all $x \in C$. X is called indecomposable if it does not contain two disjoint closed sets. A set E is called inessential if the probability of visiting E infinitely often is zero for each starting point. Otherwise it is called essential. Finally, E is called absolutely essential if it is essential but not a countable union of inessential sets. With these definitions the following is the analogue of the decomposition of an irreducible state space into a transient set and a class of persistent states each with the same period. Theorem: If X is indecomposable and absolutely essential, then there exists an integer D such that X can be written as the disjoint union $X = F \cup \bigcup_{i=1}^{D} E_i$, where F is not absolutely essential but the E_i are, and, moreover, $P(X, E_{i+1}) = 1$ for all $x \in E_i$ ($i = 1, \cdots, D$, $E_{k+1} = E_1$). D is maximal with this property and the E_i cannot be broken up further in a certain sense (Propositions 33, 44 and Definition 13).

Maruyama, Gishirô; Tanaka, Hiroshi 4109

On recurrent stationary Markoff processes. (Japanese)

Sûgaku **13** (1961/62), 30–37.

The main part of the results presented in this expository note has been published by the authors [Mem. Fac. Sci. Kyushu Univ. Ser. A **13** (1959), 157–172; MR **22** #3030]. In the first four sections of the present note, the authors reproduce almost word for word (but in Japanese) the results and proofs of the paper quoted above, except that they now follow the method of R. Z. Has'minskiĭ [Teor. Verojatnost. i Primenen. 5 (1960), 196–214; MR **24** #A3695] in constructing the invariant measure, which is somewhat simpler than the method given in the original paper. In the last section, the authors make the following remarks: (1) Some of the hypotheses made on the processes in consideration are satisfied by strong Feller processes with some additional properties; (2) If the hypotheses of the paper are satisfied by a strong Feller process, then the transition probabilities of the process are necessarily absolutely continuous with respect to the invariant measure which can be constructed by the method of the paper; (3) For a strong Feller process satisfying the hypotheses of the paper, $\lim_{t\to+\infty} T_t f(a) = (1/m(R^N)) \int f\,dm$ holds for every $f \in C(R^N)$ if it is known that the invariant measure m is finite and that the transition probabilities of the process satisfy one additional condition; (4) For diffusion processes on R^N having Brownian hitting probabilities, the speed measure (the canonical measure in the sense of Feller) is the invariant measure for the process.

Some theorems on functionals of Markov chains.

Ann. Math. Statist. **35** (1964), 1275–1290.

This paper deals with recurrent events in discrete time. It is shown that the expected waiting time, which determines whether the recurrent event is persistent, transient, or positive, may be expressed in terms of the sequence $E(Y_n)$, where Y_n is the time between n and the last occurrence before n. Subsequently, the author extends results of Dynkin and Lamperti concerning joint limit distributions for some of the functionals usually associated with recurrent events.

Port, Sidney C. 4111

Escape probability for a half line.

Ann. Math. Statist. **35** (1964), 1351–1355.

The main result, for the Markov process $S_n = S_0 + X_1 + \cdots + X_n$ of sums of the identically distributed independent random variables X_i, concerns the following escape and hitting probabilities. Let $e(x)$ denote the probability that $S_n > 0$ for all $n \geq 1$, given that the process starts at $S_0 = x$, and let Z be the place of the first visit to $(0, \infty)$, given that $S_0 = 0$. Then if $E|X_1| < \infty$ and $E(X_1) > 0$, $e(x)/E(X_1) = P[Z > -x]/E(Z)$, and $\int_{-\infty}^{\infty} e(x)\,dx = E(X_1)$. (Remark: The integral of $e(x)$ is the capacity of the set $(-\infty, 0]$, and it may be shown that $\int_{-\infty}^{\infty} e_A(x) = |E(X_1)|$ when e_A is the escape probability of any set A of infinite Haar measure, with the property that $P_x[S_n \in A$ infinitely often$] = 0$ for all x. Here $E(X_1)$ may be positive or negative, and when $E|X_1| = \infty$, the above capacity is infinite.)

Les processus de Markov et les phénomènes d'attente.

Bull. Soc. Math. Belg. **15** (1963), 45–68.

This is an expository paper about the notion of a Markov process in its elementary form. Birth-and-death processes are discussed in detail; applications to queueing theory are given. The modern notion of a Markov process in the sense of E. B. Dynkin is not mentioned.

H. Bauer (Hamburg)

Neveu, Jacques 4115

Deux remarques sur la théorie des martingales.

Z. Wahrscheinlichkeitstheorie und Verw. Gebiete **3**, 122–127 (1964).

This paper treats two distinct aspects of martingale theory. In the first part, the ergodic theorem of E. Hopf [J. Rational Mech. Anal. **3** (1954), 13–45; MR **15**, 636] is used to prove that $E[f|\mathfrak{A}_n]$ converges in the mean and with probability 1 to $E[f|\mathfrak{A}_\infty]$, where $\mathfrak{A}_\infty$ is the intersection of the decreasing sequence of Borel fields $\{\mathfrak{A}_n\}$ and f belongs to L^1 over a probability measure space (∞, Ω, P). The second part is concerned with a method of constructing a supermartingale by piecing together two supermartingales as follows. Let $\{X_t^{(i)}, \mathfrak{A}_t : t \in T\}$, $i = 1, 2$, be two supermartingales relative to the same family of Borel fields $\mathfrak{A}_t$ and let τ be a stopping time defined on $\Omega_\tau \subset \Omega$ relative to the family $\mathfrak{A}_t$. If $X_\tau^{(2)} \leq X_\tau^{(1)}$ on Ω_τ, then the process X_t equal to $X_t^{(1)}$ on the complement of $\{\tau \leq t\}$ and equal to $X_t^{(2)}$ on $\{\tau \leq t\}$ is again a supermartingale relative to the family $\mathfrak{A}_t$. This method is used to obtain an elementary derivation of an inequality due to L. E. Dubins [Illinois J. Math. **6** (1962), 226–241; MR **25** #5538] for the probability distribution of the number of upcrossings of an interval by a supermartingale.

L. L. Helms (Urbana, Ill.)

Harlamov, B. P. 4116

Some theorems on probabilistic search in a deterministic field. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **19** (1964), no. 3, 69–74.

The author considers asymptotic properties of sequences of points in an affine metric Euclidean space. The sequences are constructed according to a "search" rule that determines the statistical sampling of each next point depending on $m+1$ $(m \geqslant 0)$ immediately preceding points and on $m+1$ real numbers corresponding to these points. The correspondence between the numbers and the points is defined by a nonrandom real-valued function which is constant with respect to time. Boundedness conditions are formulated for the region of the most probable "hit" of the points of the sequence having sufficiently large indexes. Some sufficient conditions are given under which the above are fulfilled.

H. P. Edmundson (Pacific Palisades, Calif.)

Borovkov, A. A. 4117

Analysis of large deviations in boundary-value problems with arbitrary boundaries. II. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 750–767.

Part I appeared in same Ž. **5** (1964), 253–289 [MR **29** #645]. In this second part the author continues the asymptotic analysis of the first exit probabilities from a given region of a random path with vertices $(k/n, S_k/x)$, where S_k is a sum of identically distributed independent random variables. The first passage distribution is considered simultaneously with the distribution of the magnitude of the first jump from the region or with the distribution of S_n/x. In the last paragraph the hypothesis $x \sim n$ is replaced by $x = o(n)$.

Petr Mandl (Prague)

Kesten, Harry 4118

On the number of self-avoiding walks. II.

J. Mathematical Phys. **5** (1964), 1128–1137.

This is a sequel to a recent study [same J. **4** (1963), 960–969; MR **27** #2006] of the number $\chi_n(d)$ of distinct self-avoiding (s.a.) paths of length n, starting at the origin, on the lattice points of d-dimensional Euclidean space. Similarly, $\gamma_n(d)$ is the number of self-avoiding polygons (i.e., paths starting at 0 and ending at a point a distance one from 0 after n steps). The emphasis here is on estimates for the limits $\beta(d) = \lim_{n\to\infty} [\chi_n(d)]^{1/n} = \lim_{n\to\infty} [\gamma_n(d)]^{1/n}$ which are sharp when the dimension d is large. Thus, let $\chi_{n,2r}(d)$ be the number of s.a. paths of length n which do not contain any loops of lengths $2r$ or less (i.e., such paths may visit the same point more than once, but only if there are more than $2r$ steps between consecutive visits). Let $\beta_{2r}(d)$ denote the limit of the nth root of $\chi_{n,2r}(d)$. Then it is shown that $\beta_{2r}(d) - \beta(d) = O(d^{-r})$ as $d \to \infty$, and, in particular, it follows that $\beta(d) = 2d - 1 - 1/(2d) + O(1/d^2)$ as $d \to \infty$. The existence of such an asymptotic expansion was surmised by M. E. Fisher and D. S. Gaunt [Phys. Rev. (2) **133** (1964), A224–A239]. It is also shown that, for suitable constants c_1, c_2,

$$\chi_n(d) \leq [\beta(d)]^n \exp[c_1 n^{2/(d+2)} \log n]$$

and

$$[\beta(d)]^{2n-1} \exp[-c_2 n^{2/(d+1)} \log n] \leq \gamma_{2n-1}(d).$$

Dolci, Alba; Bellu, Giuseppina 4119

Il metodo della funzione generatrice nella risoluzione di problemi stocastici. (English summary)

Rend. Sem. Fac. Sci. Univ. Cagliari **33** (1963), 424–432.

The two stochastic problems considered are (i) the determination of transition probabilities and the mean and variance of their distribution, in the "simplest traffic system": Poisson input to an infinite number of exponential servers, and (ii) the determination of the same variables for the same system with Poisson input replaced by limited traffic sources. In the authors' terminology, the first problem is regarded as a birth-and-death process, the second as a machine repair problem. All results given are well known and have been given in the reviewer's book [*Stochastic service systems*, Wiley, New York, 1962; MR **24** #A3703].

J. Riordan (Murray Hill, N.J.)

Dreze, Jean-Pierre 4120

Files d'attente à plusieurs priorités relatives.

Cahiers Centre Études Recherche Opér. **4** (1962), 30–51.

Author's summary: "Cet article est consacré à l'étude des files d'attente à un guichet avec priorités relatives dont la définition et certains principes généraux sont

donnés dans l'introduction. Les arrivées de clients suivent une loi de Poisson et la durée du service, une loi exponentielle. Pour des raisons méthodologiques, nous avons cru préférable d'aborder le problème transitoire par le cas de files à trois priorités relatives pour lequel nous établissons en détail le bilan des probabilités d'états et dont nous esquissons la technique de résolution. Ensuite, nous envisageons le phénomène général à un nombre quelconque de priorités relatives en régime transitoire; la solution théorique de ce problème est présentée sous forme de fonctions génératrices des transformées de Laplace des probabilités d'état. Ces derniers résultats permettent l'étude aisée de la file en régime stationnaire: ici, nous obtenons les fonctions génératrices des probabilités d'états stationnaires, les nombres moyens de clients et, pour terminer, la moyenne et la variance du temps d'attente de chaque type de clients."

Finch, P. D. 4121

On partial sums of Lagrange's series with application to the theory of queues.

J. Austral. Math. Soc. **3** (1963), 488–490.

The author considers the partial sum of Lagrange's expansion series [Whittaker and Watson, *A course of modern analysis*, fourth edition, p. 133, Cambridge Univ. Press, Cambridge, England, 1950].

$$\phi^n(x) = \phi(x) + \sum_{m=1}^{n} (y^m/m!) D^{m-1}[(k(x))^m D\phi(x)],$$

$$D = d/dx,$$

where $k(z)$ is analytic in and on a region C surrounding x, y is such that $|yk(z)| < |z-x|$ for any z on C and $\phi(z)$ is any analytic function in and on C. He gives a recurrence relation for $\phi_j^n(x)$ which is $\phi^n(x)$ with $\phi(x) = x^j$ (the series on the right-hand side of (2.4) must be read as $\sum_{m=1}^{n+1}$). This relation with $x=0$, $y=1$ is seen to be exactly the same, including initial conditions, as one which the probability Q_j^n that the $(n+1)$st arrival finds j or more customers in the queueing system $GI/M/1$ should satisfy. The author then gives an elegant proof of

$$Q_j^n = j \sum_{j}^{n} m^{-1}[(m-j)!]^{-1}[D^{m-j}(k(x))^m]_{x=0}$$

$$(n \geq j \geq 1).$$

The right-hand sides of (2.7) and (3.3) must be replaced by this expression, where

$$k(z) = \sum_{0}^{\infty} k_m z^m \quad \text{and} \quad k_m = (m!)^{-1} \int_0^{\infty} (\mu x)^m e^{-\mu x} dA(x),$$

$A(x)$ being the distribution function of the interarrival time and μ being the parameter of exponential distribution of service time. This result was conjectured by the author [J. Austral. Math. Soc. **3** (1963), 220–236; MR **27** #4298] and was proved by Brockwell [ibid. **3** (1963), 249–256; MR **28** #5490] in a different way.

Queues with batch departures. II.

Ann. Math. Statist. **35** (1964), 1147–1156.

This is a sequel to a paper by the first author and K. M. Nyunt [same Ann. **32** (1961), 1324–1332; MR **25** #629]. The system $E_k/G/1$ is analysed in these papers in a novel way by dissecting each inter-arrival interval into k independent identically negative-exponentially distributed phases, by supposing that a sub-unit arrives at the end of each phase, and by postulating that the sub-units are aggregated as they arrive into batches of size k and served as such, with an arbitrarily specified batch-service-time. This new system is called $E_1/G^k/1$, and it differs from $E_k/G/1$ only in the way in which "the number of customers present in the system" is measured. For $E_1/G^k/1$, this random variable (called $\xi(t)$) is the number of sub-units present, while for $E_k/G/1$ the corresponding random variable (called $\zeta(t)$) is the number of complete batches present, so that $\zeta(t)$ is the integer part of $\xi(t)/k$. Thus $\zeta(t)$ can be studied if enough is known about $\xi(t)$, and the authors carry out this programme in some detail. In particular (for both systems) they compare the limiting distributions (after the lapse of a long time) of "the number present" (i) just before an arrival, (ii) just after a departure, and (iii) at an arbitrary time. For further information on the topics treated in this paper see L. Takács [Trans. Amer. Math. Soc. **100** (1961), 1–28] and R. R. P. Jackson and D. G. Nichols [J. Roy. Statist. Soc. Ser. B **18** (1956), 275–279; MR **18**, 681].

An application of the methods of statistical decision functions to a question of optimal parameters in a control problem. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **35** (1964), 23–28.

Decision-theoretic treatment of a problem arising in queueing theory. *J. G. Wendel* (Ann Arbor, Mich.)

Greenberg, Irwin 4124

The distribution of busy time for a simple queue.

Operations Res. **12** (1964), 503–504.

In a queue with a single channel, Poisson arrival times and exponential service times, let t be the busy time in an interval of given duration. The author proposes to infer the distribution of t by reducing the queueing process to a two-state process, in which the states are "busy" and "idle", and then applying some known results. Unfortunately, this two-state process is not Markovian, and this seems to invalidate the author's method.

The formula for the distribution of the first busy period starting with a queue of length q, cited from Takács [*Introduction to the theory of queues*, p. 38, Oxford Univ. Press, New York, 1962; MR **24** #A3704], can be expressed more simply: see the reviewer's derivation [discussion of Kendall, J. Roy. Statist. Soc. Ser. B **13** (1951), 151–185, pp. 182–183; MR **13**, 957]. *I. J. Good* (Oxford)

Hasofer, A. M. 4125

A dam with inverse Gaussian input.

Proc. Cambridge Philos. Soc. **60** (1964), 931–933.

This paper studies the dam of infinite capacity, with input $X(t) \geq 0$ in time t following an infinitely divisible distribution, and subject to release at constant unit rate ceasing when the dam is empty.

The author points out that for the previously studied

Gamma type input of this kind, functions describing the transient behavior of the content $Z(t)$ of the dam are known, but cannot be calculated in closed form [J. Gani and N. U. Prabhu, same Proc. **50** (1963), 417–430; MR **26** #4425]. He shows that for the inverse Gaussian input with the density function

$$\frac{t}{\sigma\sqrt{(2\pi)}}\left(\frac{\rho}{x}\right)^{3/2}\exp\left\{-\frac{\rho}{2\sigma^2 x}(x-\rho t)^2\right\}$$

it is possible to obtain explicit results for (1) the distribution of time to first emptiness, (2) the probability of emptiness, (3) the expectation of the content, and (4) the Laplace transform of the content $Z(t)$ of the dam.

J. Gani (E. Lansing, Mich.)

Freund, John E. 4126

★Mathematical statistics.

Prentice-Hall, Inc., Englewood Cliffs, N.J., 1962. xiii + 390 *pp.* $10.35.

This admittedly non-rigorous textbook is written for an introductory two-semester course with the prerequisite of undergraduate knowledge in calculus. Thus it is destined for a specific age public. The fourteen chapters starts with statements of the problems, followed by a small number of logically well-separated paragraphs and clearly formulated theorems and end with stimulating exercises, some taken from quality control and operations research (without mentioning this name). Solutions for one half of the exercises are shown at the end (why only one half?). References, but in insufficient number, are given after most of the chapters. Articles from journals are only rarely cited. An appendix contains the usual statistical tables and the binomial probabilities. Thus the book tries to be self-contained. Lengthy discussions which would deter from the main point are omitted. On the whole, it meets its aims.

After a short introduction on set theory come three chapters on discrete variables, binomial, multinomial, hypergeometric and Poisson's distributions and their moments. As usual, the binomial distribution is used to obtain the law of large numbers. However, its different forms and philosophical implications are not stated. The discrete uniform, the geometric and the negative binomial distributions are mentioned only in the exercises. Quite late, in the fifth chapter, continuous variables, the uniform, the exponential, the Gamma and the normal distributions are stated. The derivation of the normal distribution from the binomial one is given only in the next chapter. The Pearson system should merit a systematic treatment, not only a notice in the exercises. The logarithmic normal distribution and the use of probability papers are not mentioned. The sums of random variables in Chapter 7 lead to the central limit theorem obtained by the moment-generating function. The next chapter, dealing with sampling distributions, studies the mean, variance, the chi-square, and the F- and t-distributions. The important proof for the independence of mean and variance is left to the reader.

Maximum likelihood method and confidence intervals form Chapters 9 and 10. Two chapters follow on the test of hypothesis against a single alternative. Only one chapter is devoted to regression and correlation and the final one to the analysis of variance. Many bivariate distributions, not only the usual normal one, are studied. This has definite merit, but the conditions for a bivariate function to be a bivariate distribution are not sufficiently clearly stated. In some graphs only one of the regression curves is shown.

The distinction between the probability function $F(x)$ (distribution) as opposed to the density function $f(x)$ is not sufficiently clear because sometimes a density function is also called a distribution. To make things worse, the probability of a certain value for a discontinuous variable is designated by the same symbol as the density of probability. It is sad that such time-dishonored impurities persist in a new book. On page 226, the reader is asked to find the (non-existent) maximum likelihood estimates for the two parameters of a curtailed exponential distribution.

E. J. Gumbel (New York)

Brittain, John A. 4127

Interpolation of frequency distributions of aggregated variables and estimation of the Gini concentration measure.

Metron **22** (1962), 98–109.

Economic research sometimes deals with empirical frequency distributions with gaping unequal class intervals but also with information about the aggregate of the variable within the interval. Consider a basic variable, X, representing income level. Let $F=F(X)$ be the number of incomes greater than X, and let A be the aggregate income accruing to the F incomes greater than X. First, with unequal class intervals of X, the Newton expansion using divided differences for observed F_i can be used in obtaining an approximating polynomial for estimating A for any F, $A(F)$, and this can be differentiated to estimate the X associated with that F, $X(F)$. Second, an adaptation of Simpson's rule can be used in obtaining an approximation to the Gini coefficient. Numerical illustrations are given.

P. S. Dwyer (Ann Arbor, Mich.)

Sevast'janov, B. A.; Čistjakov, V. P. 4128

Asymptotic normality in the classical problem of balls. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 223–237.

Consider a scheme of independent sampling, with replacement, of n objects from a population of size N; μ_r is the number of objects in the population selected exactly r times. (For example, if n balls are dropped into N boxes, μ_r is the number of boxes containing exactly r balls.) The principal result of this paper is a multivariate local limit theorem for $\mathbf{P}(\mu_{r_1}=k_1,\cdots,\mu_{r_s}=k_s)$ as $n, N\to\infty$. With the provision that $0<\alpha_0\leq n/N\leq\alpha_1<+\infty$ for all n, N, the authors show that $\mathbf{P}(\mu_{r_1}=k_1,\cdots,\mu_{r_s}=k_s)=\Phi(k_1,\cdots,k_s)\cdot(1+O(N^{-1/2}))$, where $\Phi(k_1,\cdots,k_s)$ is a multivariate normal density whose covariance structure is determined by N and n/N.

R. F. Gundy (Ann Arbor, Mich.)

Abrahamson, I. G. 4129

Orthant probabilities for the quadrivariate normal distribution.

Ann. Math. Statist. **35** (1964), 1685–1703.

Author's summary: "Let x_1, x_2, x_3, x_4 be jointly distributed with a quadrivariate normal distribution with mean 0, and correlation matrix $\{\rho_{ij}\}$. The orthant probability, i.e., the probability that all the x_i's will be simultaneously positive, is not, in general, given by a closed expression, but is easily computed in a special class of cases, here called orthoscheme probabilities. It is explicitly shown how the general orthant probability can be expressed as a linear combination of six orthoscheme probabilities. Orthoscheme probabilities have been tabulated by the author and instructions for the use of this table are given. In addition, an abridged table is appended."

Beckmann, Petr 4130

Rayleigh distribution and its generalizations.

J. Res. Nat. Bur. Standards Sect. D **68D** (1964), 927–932.

In many problems in radio wave propagation the resultant field is formed by the superposition of a number of elementary vectors:

$$Ee^{i\theta} = \sum_{j=1}^{n} E_j e^{i\phi_j}.$$

The distribution of (E, θ) is considered under various assumptions on the vectors (E_j, ϕ_j) and n, including the following cases: (a) the distributions of phases, θ_j, are not uniform, (b) one or more vector terms predominate, (c) n is a random variable. The arguments are informal and non-rigorous (sometimes erroneous).

Feigel'son, T. S. 4131

On a simple method of establishing the independence of statistics. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **19** (1964), no. 3, 157–158.

Author's summary: "Let **P** be a family of distributions of X. The statistic $f(X)$ is named zonal if its distribution is the same for all $P \in \mathbf{P}$. It is proved that if a family of distributions of a sufficient statistic T for **P** is complete, no zonal statistic depends on T. n-dimensional random variables

$$X_i = \begin{vmatrix} X_{i1} \\ \cdot \\ \cdot \\ \cdot \\ X_{in} \end{vmatrix}, \qquad i = 1, \cdots, N;\ N \geq 4n;\ X_i \in N(A, \Lambda),$$

are considered, and a zonal statistic independent of the system of sufficient statistics is constructed."

J. Wolfowitz (Ithaca, N.Y.)

Gebhardt, Friedrich 4132

Generating normally distributed random numbers by inverting the normal distribution function.

Math. Comp. **18** (1964), 302–306.

Polynomial approximations of the inverse function, $\psi(t)$, of the cumulative normal distribution function are provided for use in transforming uniformly distributed random numbers into normally distributed ones. Table 1 gives values, a_n and b_n, of the linear approximation $a_n + b_n t$ of $\psi(t)$ having maximum error $\varepsilon_M = 0.0004$ for $8 \leq n \leq 15$ and $\varepsilon_M = 0.0001$ for $16 \leq n \leq 49$, with $n/100 \leq t \leq (n+1)/100$. Table 2 presents approximations of $\psi(t)$ by polynomials of second, third, and fourth degree. Explanatory comments lead to a statement about the computer program.

Guenther, William C. 4133

Another derivation of the non-central chi-square distribution.

J. Amer. Statist. Assoc. **59** (1964), 957–960.

The author uses spherical coordinates to give a new and relatively short derivation of the non-central chi-square distribution. *H. B. Mann* (Madison, Wis.)

Gumbel, E. J.; Goldstein, Neil 4134

Analysis of empirical bivariate extremal distributions.

J. Amer. Statist. Assoc. **59** (1964), 794–816.

Two types of bivariate distributions whose marginal distributions are extremal are discussed: independent and homotopically dependent. A graphical test of each of these special cases is proposed; $mm'/(n+1)^2$ is plotted against the values $k/(n+1)$ of the cdf of p, where m and m' are the marginal ranks, k is the rank of mm', n is the sample size and the cdf of p is $p(1-\ln p)$ for independence, while it is $1/(2\sqrt{p})$ for the case of homotopic dependence $(m = m')$. Two chi-square tests of independence, one based on the octants about the medians and the other based on equiprobable regions, are presented. These ideas are illustrated by (a) the distribution of oldest ages at death of the two sexes and (b) floods of the same river recorded at two stations. The marginal distributions are extremal of the first type; (a) illustrates independence, while (b) illustrates homotopic dependence. An appendix contains a proof (due to Pickands) that asymptotic independence of the relative ranks implies independence of the variables themselves. *D. R. Barr* (Dayton, Ohio)

Nadaraja, È. A. 4135

Some new estimates for distribution functions. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 550–554.

Given a sequence of independent, identically distributed random variables $x_1, x_2, \cdots, x_n$ with the common distribution function F and continuous density f, the author examines estimates of the form $F_n(x) = \int_{-\infty}^{x} f_n(x')\,dx'$ for $F(x)$, where

$$(*) \qquad f_n(x) = \frac{1}{nh(n)} \sum_{i=1}^{n} K\left(\frac{x - x_i}{h(n)}\right)$$

and K is a density function.

Under suitable conditions on h and K the asymptotic unbiasedness and consistency of the $F_n(x)$ are proved and sufficient conditions on h, K, and f insuring the consistency and asymptotic normality of sample quantiles ζ_p of the form $F_n(\zeta_p) = p$ are found.

Although it is not mentioned explicitly in the Russian text, this paper is based on and follows closely E. Parzen's paper [Ann. Math. Statist. **33** (1962), 1065–1076; MR **26** #841], where a corresponding but more detailed examination of estimates f_n of the form (*) for the density function and sample mode is presented.

{The Lemma of the paper is a corollary of "Scheffé's convergence theorem" [ibid. **18** (1947), 434–438; MR **9**,

83] but only if the asymptotic unbiasedness of f_n, proved in Parzen's paper [loc. cit.], is assumed.}

Rider, Paul R. 4136
Distribution of product and of quotient of maximum values in samples from a power-function population.
J. Amer. Statist. Assoc. **59** (1964), 877–880.
The function

$$\begin{aligned} F(x) &= 0 && \text{for } x<0, \\ &= (x/\xi)^{k+1} && \text{for } 0 \le x \le \xi, \\ &= 1 && \text{for } x \ge \xi \end{aligned}$$

is called by the author the power function distribution. He considers the maxima L_1 and L_2 of two independent samples of size m and n, respectively. The author determines the distribution of the product $u = L_1 L_2$ and of the quotient $v = L_2/L_1$ and discusses also the estimation of the parameters. *E. Lukacs* (Washington, D.C.)

Siddiqui, M. M. 4137
Statistical inference for Rayleigh distributions.
J. Res. Nat. Bur. Standards Sect. D **68D** (1964), 1005–1010.
The content of this paper can be summed up as follows. The Rayleigh distribution, $F(r) = 1-e^{-r^2/\alpha^2}$, $r \ge 0$, is transformed into the exponential distribution $G(z) = 1-e^{-z/\alpha^2}$, $z \ge 0$, by the change of variable $z = r^2$. Hence methods of statistical inference for the exponential distribution are directly translatable into methods for the Rayleigh distribution.
Benjamin Epstein (Palo Alto, Calif.)

Jones, Richard Hunn 4138
Spectral estimates and their distributions. I, II.
Skand. Aktuarietidskr. **1962**, 39–69 (1963); *ibid.* **1962**, 135–153 (1963).
Much of the material in both of these papers is expository and historical. That which is novel is outlined in the author's summary: "Methods of choosing spectral windows for estimating the spectral density of a stationary time series are discussed, and a generalization of the 'hanning' and 'hamming' spectral windows presented. By using the concept of spectral window bandwidth, 'optimal' discrete spectral windows are derived. Spectral estimates are given for stochastic processes, the time points of which are chosen using an additive random scheme, and a method suggested for handling any unequally spaced data. It is shown that when estimating the two-dimensional spectral density of a harmonizable stochastic process (non-stationary), nothing is gained by smoothing the periodograms. Also, a test for stationarity of a periodic harmonizable stochastic process is given. Two methods are presented for the numerical calculation of the frequency function of a quadratic form in normal variates. A modified Laguerre series using a Type III approximation as its weight is used when the eigenvalues of the matrix are non-negative and closely grouped. The second method uses the saddle-point approximation and method of steepest descent to invert the characteristic function, and is useful for any real eigenvalues. An asymptotic expression for the frequency function for large values of the argument is given, which can be used to obtain an upper confidence limit of an estimate."

Hannan, E. J. 4142
The general theory of canonical correlation and its relation to functional analysis.
J. Austral. Math. Soc. **2** (1961/62), 229–242.
In der klassischen Theorie der kanonischen Korrelation wird die lineare Abbildung A eines Raumes von p zufälligen Variablen $x_1, \cdots, x_p$ in einen Raum von q zufälligen Variablen $y_1, \cdots, y_q$ untersucht. Durch Hauptachsentransformation von A gewinnt man sogenannte kanonische Variable. Für A, lineare Funktionen der Variablen x bzw. y und deren Skalarprodukte gelten bestimmte Zerlegungssätze. Diese Ergebnisse werden mit Hilfe von Spektralzerlegungen linearer Operatoren im Hilbertraum verallgemeinert: Es werden zwei Familien $\{x_s, s \in S\}$, $\{y_t, t \in T\}$ von Zufallsgrößen und die kanonische Korrelation zwischen Funktionen dieser Zufallsgrößen betrachtet. Sind die Indexmengen S und T endlich und ist die gemeinsame Verteilung $H(x, y)$ bezüglich der marginalen Verteilungen $M(x)$ und $N(y)$ absolut stetig, so läßt sich der lineare Operator A durch die Radon-Nikodymsche Ableitung $A(x, y) = \partial H(x, y)/\partial M(x)\partial N(x)$ ausdrücken. Die

im Falle Gaußscher Prozesse bekannte Formel für die in den x-Variablen enthaltene Information über die y-Variablen wird verallgemeinert. Für den Fall unendlicher Indexmengen wird die Theorie für stationäre Gaußsche Prozesse und aufeinanderfolgende Beobachtungen eines vektoriellen stationären Gaußschen Prozesses entwickelt.

Khatri, C. G. 4143
Some more estimates of circular probable error.
J. Indian Statist. Assoc. 1 (1963), 40–47.

Let $\{X_i\}$ ($i=1, \cdots, n$) be NID with mean zero, variance σ^2, and let $F(r)$ denote the distribution of $r=(\sum_{i=1}^n X_i^2)^{1/2}$. The circular probable error (CEP) is given by the root of the equation $F(r)=0.5$ and is therefore a linear function of σ. The author lists eight estimates of CEP that have previously been given; in this paper, two additional estimates are given. These depend on (1) Gini's mean difference, and (2) mean square successive differences of the X_i.

For the second of these new estimates, the author derives the distribution of the estimate, obtaining it in infinite series form involving Laguerre polynomials, thus enabling him to determine the appropriate multiplier so that the estimator is unbiased. He then tabulates the variance and efficiencies (relative to the minimum variance unbiased estimate) of these two estimates.

Pratt, John W. 4144
Robustness of some procedures for the two-sample location problem.
J. Amer. Statist. Assoc. 59 (1964), 665–680.

Author's summary: "The level of ordinary two-sample procedures is not preserved if the two populations differ in dispersion or shape. The effect of such differences, especially differences in dispersion, on the t, median, Mann-Whitney, and normal scores procedures is investigated asymptotically, and tables are given comparing the four procedures." *W. Hoeffding* (Calcutta)

Rothenberg, Thomas J.; Fisher, Franklin M.; Tilanus, C. B. 4145
A note on estimation from a Cauchy sample.
J. Amer. Statist. Assoc. 59 (1964), 460–463.

In the estimation of the centre of the Cauchy distribution, it is well known that the sample-mean is an inconsistent estimator, the sample-median is consistent but inefficient, and the maximum likelihood estimator is asymptotically efficient but difficult to calculate.

The authors propose a class of estimators based on the sample order statistics. Each estimator in the class is the arithmetic average of a central subset of the sample of order statistics. Although the sample-median is a member of the proposed class, it is not the most efficient. It is shown that the average of roughly the middle quarter of the ordered sample has the lowest asymptotic variance, and that the use of this estimator in place of the median eliminates nearly half of the efficiency loss.
V. S. Huzurbazar (Poona)

Meredith, William 4146
Canonical correlations with fallible data.
Psychometrika 29 (1964), 55–65.

The canonical correlation coefficient measures the extent to which a linear form of the p variables, x, can be correlated with a linear form of the q variables, y. Even though this correlation for the linear forms of x and y were unity, appreciable errors in the observed x and y would presumably result in a correlation less than unity. In an attempt to compensate for this shrinkage, a correlation coefficient is said to be corrected for attenuation when it is divided by the product of the square roots of the two reliabilities. The author determines sets of weights so as to maximize the correlation between the linear composites after correction for attenuation in the composites and finds that the results may be obtained by determining the canonical correlations and canonical regression weights between the true score components of the measures making up the two sets. In addition, formulae are developed for calculating the correlations between the canonical variates and original measures, both corrected and uncorrected for attenuation. A numerical illustration is provided.

Nadaraja, È. A. 4147
On a regression estimate. (Russian. English summary)
Teor. Verojatnost. i Primenen. 9 (1964), 157–159.

For the bivariate random variable (X, Y), the regression of Y on X is $\bar{y}(x)=E(Y|x)$. Starting with the family of estimators for a probability density studied by Parzen [Ann. Math. Statist. 33 (1962), 1065–1076; MR 26 #841], the author proposes the estimator $\bar{y}_n(x)=\sum_1^n c_i(x)y_i/\sum_1^n c_i(x)$, where $c_i(x)=K((x-x_i)/h(n))$, $K(x)$ is a density function satisfying conditions similar to Parzen's, and $h(n)\to 0$ as $n\to\infty$. Three theorems on asymptotic properties of $\bar{y}_n(x)$ are stated.
J. R. Rosenblatt (Arlington, Va.)

Telser, Lester G. 4148
Iterative estimation of a set of linear regression equations.
J. Amer. Statist. Assoc. 59 (1964), 845–862.

This paper deals with the problem of estimating a set of interdependent linear regression equations. It has been assumed that the explanatory variables are nonstochastic and the disturbances of at least one pair of equations are correlated. Koopmans-Rubin-Leipnik's one-at-a-time least squares estimates are efficient if exactly the same explanatory variables (with the same observations) enter into each of the equations. In case the explanatory variables are different in at least one pair of equations and for this pair the disturbances are correlated, Zellner proposed an estimator based on Aitken's generalized least squares method. He has shown the gain in efficiency by use of this method.

The author considers the case when either (a) different explanatory variables enter various equations or (b) if the same explanatory variables enter, then the observations are different. An iterative method of deriving the coefficient estimates is proposed. The iterative estimates obtained in this way possess the same asymptotic properties as the estimates given by Zellner. Although Zellner's estimates are computationally simpler, the analysis of the iterative

procedure shows how the relations among the residuals of various equations can be exploited to obtain asymptotically efficient estimates. *A. L. Nagar* (Delhi)

Rossberg, Hans-Joachim 4149

Über das asymptotische Verhalten der Rand- und Zentralglieder einer Variationsreihe. I. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. 8 (1963), 463–468 (1964).

The author proves the following result. Two order statistics x_h and x_k of a continuous variable are asymptotically independent if $\lim_{n\to\infty} (h/k) = 0$. The same holds for x_{n+1-h} and x_{n+1-k}. The proof follows a method of Rényi [Acta Math. Acad. Sci. Hungar. 4 (1953), 191–231; MR 15, 885] and is based on the exponential distribution of $y = -\lg[1-F(x)]$. It eliminates the condition on the initial variable made previously by this reviewer [Ann. Math. Statist. 17 (1946), 78–81; MR 7, 464]. *E. J. Gumbel* (New York)

Krem, Alajos 4150

On the independence in the limit of extreme and central order statistics. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. 8 (1963), 469–474 (1964).

This paper gives another proof for the statement in the previous review [#4149]. The asymptotic independence of the order statistics does not hold for the central members of a normal distribution. *E. J. Gumbel* (New York)

Snow, Barbara A. S. 4151

The distribution of Kendall's tau for samples of four from a normal bivariate population with correlation ρ.

Biometrika 50 (1963), 538–540.

The only possible values of tau, in samples of four, are the seven values -1 (1/3) 1. The permutations of 1234 having values are shown in Table 1. The frequencies of positive tau as a power series in $\theta_1 = \sin^{-1}\rho$ and $\theta_2 = \sin^{-1}\frac{1}{2}\rho$ are given in Table 2, and the power series in ρ in Table 3, where the population is normal bivariate. A sampling experiment with $n=4$, $\rho = 1/\sqrt{2}$ is used as an illustration. *P. S. Dwyer* (Ann Arbor, Mich.)

Pearson, E. S.; Stephens, M. A. 4152

The goodness-of-fit tests based on W_N^2 and U_N^2.

Biometrika 49 (1962), 397–402.

The authors give some results on the performance in small samples of the Cramér-von Mises-Smirnov type of statistics

$$W_N^2 = N\int_{-\infty}^{\infty} [F_N(x)-F(x)]^2\,dF(x),$$

$$U_N^2 = N\int_{-\infty}^{\infty}\left\{F_N(x)-F(x)-\int_{-\infty}^{\infty}[F_N(y)-F(y)]\,dF(y)\right\}^2 dF(x),$$

the latter being a statistic introduced by G. S. Watson [Biometrika 48 (1961), 109–114; MR 24 #A1777; ibid. 49 (1962), 57–63; MR 25 #1626], in discussing goodness-of-fit tests on a circle. In the expressions above, $F(x)$ is the theoretical cumulative distribution function (c.d.f.) of the random variable x, and $F_N(x)$ the sample c.d.f. for a sample of size N.

Percentage points of W_5^2 and W_{10}^2 have been obtained from Johnson's four-parameter S_B curves having the correct first four moments. Large-scale Monte Carlo sampling has been used to derive percentage points of W_{10}^2 and U_{10}^2. These are compared, respectively, with the percentage points of W_∞^2 and U_∞^2. A relationship between the cumulants of W_∞^2 and U_∞^2 has been established. *I. M. Chakravarti* (Chapel Hill, N.C.)

The distribution of the goodness-of-fit statistic U_N^2. I.

Biometrika 50 (1963), 303–313.

The goodness-of-fit statistic

$$U_N^2 = N\int_{-\infty}^{+\infty}\left\{F_N(x)-F(x)-\int_{-\infty}^{\infty}[F_N(y)-F(y)]\,dF(y)\right\}^2 dF(x)$$

introduced by Watson [Biometrika 48 (1961), 109–114; MR 24 #A1777] is independent of the origin and hence can also be used to test the randomness on a circle. On the null hypothesis that $F(x)$ is the true probability function, U_N^2 is distribution-free. Therefore, $F(x)$ may be assumed to be the uniform distribution (0, 1). For the computation the sample value $F_N(x_i)$ is replaced by $(i-0.5)/N$, where i is the rank. {This reviewer objects, and prefers the expected value $i/(N+1)$ of $F_N(x_i)$.} The author gives the first four moments of U_N^2 for any N, the exact probability function for $N = 1, 2, 3$, its lower tail for $N > 3$ and associated tables of moments and significance points. They indicate rapid convergence to the asymptotic distribution. The derivations, based on geometric interpretations, are very complicated. *E. J. Gumbel* (New York)

Pearson, E. S. 4154

Comparison of tests for randomness of points on a line.

Biometrika 50 (1963), 315–325.

This article is a sequel to the preceding one [#4153]. In addition to U_N^2, it lists three other similar goodness-of-fit tests, namely,

$$W_N^2 = N\int_{-\infty}^{+\infty}[F_N(x)-F(x)]^2\,dF(x),$$

$$D_N = \sup_{-\infty\le x\le\infty} |F_N(x)-F(x)|,$$

$$V_N = \sup_{-\infty\le x\le\infty}\{F_N(x)-F(x)\} - \inf_{-\infty\le x\le\infty}\{F_N(x)-F(x)\}.$$

Their distribution on the null hypothesis is distribution-free. Therefore, it is sufficient to consider the distribution of points on a line. The assumption for $F_N(x)$ is the same as in the previous article. The results of the four tests are compared for different sets of data which are not independent, warp breaks on a loom, times of road accidents, fatal explosions in a coal mine, and the lengths of reigns of English kings and queens; finally, artificial series with changing expectations. The U_N^2 and V_N tests turn out to

be more sensitive for departures from randomness than $W_N{}^2$ and D_N. However, as the author states, such numerical work cannot establish anything final.

Čibisov, D. M. 4155

On the asymptotic power of goodness-of-fit tests for near alternatives. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 561–562.

Let $G_n{}^*(u)$ be the empirical distribution function (df) of a sample of size n from a df $G_n(u)$ on $[0, 1]$, and let $\beta_n(u) = n^{1/2}(G_n{}^*(u) - u)$. Let $\beta(u)$ be the Gaussian process with $M\beta(u) = 0$, $M\beta(u)\beta(v) = \min(u, v) - uv$. Suppose that $n^{1/2}(G_n(u) - u) \to \delta(u)$ as $n \to \infty$. Sufficient conditions are given for $\beta_n(u)$ to converge to $\beta(u) + \delta(u)$, in a sense defined by Prohorov [Teor. Verojatnost. i Primenen. 1 (1956), 177–238; MR 18, 943].

Lindley, Dennis V. 4158

The Bayesian analysis of contingency tables.

Ann. Math. Statist. **35** (1964), 1622–1643.

The author describes how data from a multinomial distribution, and, in particular, data in the form of a contingency table, may be studied by using a prior distribution of the parameters and expressing the results in the form of a posterior distribution, or some aspects thereof, of the parameters. The analysis used depends on the prior distribution, and the form given in Theorem 1 only applies to a certain type of prior knowledge. Theorem 1: If the random variables $n_1, n_2, \cdots, n_k$ have a multinomial distribution with parameters $\Theta_1, \Theta_2, \cdots, \Theta_k$; and if the prior distribution of the Θ_i has density proportional to $(\prod \Theta_i)^{-1}$ over the region $\Theta_i \geq 0$, $\sum \Theta_i = 1$; then if the constants a_{pi} ($p = 1, 2, \cdots, m$; $i = 1, 2, \cdots, k$; $m < k$) satisfy $\sum_i a_{pi} = 0$, the joint posterior distribution of the contrasts $\sum_i a_{pi} \ln \Theta_i$ ($p = 1, 2, \cdots, m$) is approximately normal with means $\sum_i a_{pi} \ln n_i$ and covariances $\sum_i a_{pi} a_{qi} n_i{}^{-1}$. The author gives reasons for believing the type of prior distribution used to be of frequent occurrence. For application to contingency tables the author proves Theorem 2: If the prior distribution of Θ_{ij} ($i = 1, 2, \cdots, r$; $j = 1, 2, \cdots, s$) is proportional to $\prod_{ij} \Theta_{ij}{}^{-1}$, then the prior distribution of Θ_i and $\Phi_{ij} = \Theta_{ij}/\Theta_i$ is proportional to $\prod_i \Theta_i{}^{-1} \prod_{i,j} \Phi_{ij}{}^{-1}$. The author examines the connection between the methods he proposes and the analysis of variance, particularly with a view to simplifying the analysis of contingency tables involving three or more factors.

Shrikhande, S. S. 4162

Generalized Hadamard matrices and orthogonal arrays of strength two.

Canad. J. Math. **16** (1964), 736–740.

The author indicates some relationships among generalized Hadamard matrices, group divisible designs, affine resolvable balanced incomplete block designs and orthogonal arrays of strength two. Several theorems which pertain to the construction of orthogonal arrays are also presented.

S. Addelman (Durham, N.C.)

Paulson, Edward 4163

Sequential estimation and closed sequential decision procedures.

Ann. Math. Statist. **35** (1964), 1048–1058.

A sequential procedure for estimating the mean of a normal distribution is given and the results applied to the problem of deciding which of k disjoint intervals contains the mean. Sequential confidence limits are derived for the variance and the ratio of variances of normal distributions.

The results are applied to get closed decision procedures in (a) testing a hypothesis on the mean or variance of a normal distribution, (b) comparing the means or variances of k experimental categories with a standard, (c) testing hypotheses about the ratio of variances. A discussion about the construction of confidence intervals for a parameter after a decision has been reached is provided.
M. Katz (Detroit, Mich.)

Phatarfod, R. M. 4164

Large sample sequential analysis of Markovian observations.

J. Indian Statist. Assoc. 1 (1963), 152–160.

Asymptotic sampling properties of Wald's sequential probability ratio test are obtained where (a) the two hypotheses are close, requiring a large sample for discrimination, and (b) the successive observations form an ergodic Markov chain. Hypotheses depending on one and two parameters are discussed. The results extend those of Bartlett [Proc. Cambridge Philos. Soc. **42** (1946), 239–244; MR 8, 471], who derives properties assuming that the observations are independent. *M. Katz* (Detroit, Mich.)

Grettenberg, Thomas L. 4165

The ordering of finite experiments.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 193–206. *Publ. House Czech. Acad. Sci., Prague*, 1964.

The author considers the expected-loss criteria in decision problems for comparing experiments with a common input space and with different input spaces. Of the two experiments P and Q, suitably defined in terms of a Markov matrix with a common input space, P is preferred to Q if each loss vector attainable with Q is also attainable with P. If P and Q are comparable, then the expected values of their information measures I_P and I_Q are also comparable. Several equivalent conditions are reviewed relating to a common input space and also to input spaces of unequal dimensions. Then various implications of the expected-loss comparison are discussed. In particular, it is shown that a discriminatory-information inequality may also be obtained from the expected loss comparison.
M. Atiqullah (Dacca)

Pathak, P. K. 4166

On sampling schemes providing unbiased ratio estimators.

Ann. Math. Statist. **35** (1964), 222–231.

Ratio estimators are valuable in sampling problems where the value of an auxiliary variable is known for the entire population. Thus, if one samples Y and W, where W is the auxiliary random variable, an estimate of the ratio $R=\sum Y/\sum W$, where the sums are taken over the entire population, together with the known value $\sum W$, can be used to estimate $\sum Y$. The author extends a result of Nanjamma, Murthy, and Sethi [Sankhyā **21** (1959), 299–314; MR **22** #3086], who discussed a ratio estimator $\hat{R}=F/G$ which is a ratio of estimates of $\sum Y$ and $\sum W$ and would be biased under the original sampling scheme, but is unbiased if the sampling scheme is modified slightly. A uniformly better unbiased estimator, the conditional expectation of $\hat{R}$ given a sufficient statistic, is shown to be equal to F_T/G_T, where F_T and G_T would be the conditional expectations of F and G under the original sampling scheme. This result is applied with sophistication to a number of sampling schemes, including sampling with equal and unequal probabilities (with replacement), stratified sampling and two-stage sampling. The key to the easily derived result and its main contribution lies in the set-up which, partly because of its generality, is vaguely stated and was difficult for the reviewer to comprehend. For example, it is not made clear in the original description of the set-up that the sample ω may be described by the frequencies with which each element of the population is observed, ignoring the order in which they are observed. But this is precisely the case for the simplest applications. The main idea seems to have considerable potential value. *H. Chernoff* (Stanford, Calif.)

Roberts, Charles DeWitt 4167

An asymptotically optimal fixed sample size procedure for comparing several experimental categories with a control.

Ann. Math. Statist. **35** (1964), 1571–1575.

Author's summary: "The basic problem considered here involves k experimental categories. The experimenter must decide none of the k categories is better than the control or decide a certain category is better. For this problem a fixed sample size procedure δ_n^* is given. With a definite loss function and a cost $c>0$ per observation, δ_n^* and other fixed sample size procedures are compared in a certain asymptotic sense as $c\to 0$. In particular, δ_n^* is shown to be an optimal fixed sample size procedure in this asymptotic sense. By appealing to asymptotic results the procedure δ_n^* is compared with sequentially designed procedures."

Seber, G. A. F. 4168

The linear hypothesis and large sample theory.

Ann. Math. Statist. **35** (1964), 773–779.

Let us consider n independent observations $x_1, \cdots, x_n$ from a population with a density $f(x, \theta)$, where $\theta=(\theta_1, \theta_2, \cdots, \theta_s)$ is an unknown vector with real parameters belonging to a subset Ω of s-dimensional Euclidean space. Further, let ω_1, ω_2 be $(s-r)$-dimensional subsets of Ω and suppose that the hypotheses $\theta\in\omega_i$ have to be tested. Following Aitchison [J. Roy. Statist. Soc. Ser. B **24** (1962), 234–250; MR **25** #3586] the author calls the hypotheses ω_1, ω_2 separable with respect to Ω if and only if the critical region for testing $\omega_i\cap\omega_j$ against $\omega_j-\omega_i\cap\omega_j$ is the same as that for testing ω_i against $\Omega-\omega_i$. Assuming that the sets ω_i are defined in terms of freedom equations, i.e., $\omega_i=\{\theta:\theta\in\Omega, \theta=\theta_i(\beta_i)\}$, where $\theta_i(\beta_i)$ is a function of an $(s-r_i)$-dimensional vector β_i, the author demonstrates asymptotic equivalence of the hypotheses considered as certain linear hypotheses and derives sufficient conditions for the separability of ω_1 and ω_2.

Gardner, L. A., Jr. 4169

Adaptive predictors.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 123–192. *Publ. House Czech. Acad. Sci., Prague*, 1964.

When the covariance function of a second-order stationary time series is known, then the optimum linear predictor based on the "last" p observations is known and the p coefficients can be obtained by inverting an appropriate matrix. The author is concerned with estimating the optimum coefficients when the covariance function is unknown and observations are taken sequentially. He discusses the asymptotic behavior of three methods, the first of which is to estimate at time n the covariance function and then use it as if it were the "true" covariance function, while the other two are recursive schemes which avoid the complexity of matrix inversion. These recursive schemes are stochastic approximation procedures which are closely related to the generalizations of the Robbins-Monro procedure in p-dimensions (see, for example, this reviewer [Ann. Math. Statist. **29** (1958), 373–405; MR **20** #4886]) but differ, primarily, in that the errors are not conditionally independent as they usually are in the literature of stochastic approximation. However, the author is able to successfully adapt the methods of previous authors, such as in the above reference, to prove convergence and asymptotic normality in the present context.

J. Sacks (Evanston, Ill.)

Jorgenson, Dale W. 4170

Minimum variance, linear, unbiased seasonal adjustment of economic time series.

J. Amer. Statist. Assoc. **59** (1964), 681–724.

The time series $\{y_t\}$ is assumed to satisfy the model $y_t = d_t + s_t + \varepsilon_t$, $t = 1, \cdots, N$, where $\{d_t\}$ is a deterministic trend, $\{s_t\}$ is a seasonal component and $\{\varepsilon_t\}$ is a series of uncorrelated errors with zero mean and constant variance. One method of estimating the seasonal component is to filter the series by means of a filter L designed to eliminate as much of the trend as possible. The filtered seasonal component $\{Ls_t\}$ is efficiently estimated by Aitken's generalised least squares, and from this an estimate of the original component $\{s_t\}$ is obtained. An alternative method is to fit the model $y_t = d_t' + s_t + \varepsilon_t$, where d_t' is the general solution of the difference equation $Ld_t' = 0$, by ordinary least squares. The paper demonstrates that the two estimates are identical and discusses some implications.

J. Durbin (London)

Šeff', O. [Šefl, O.] 4171

Some questions of automatic control of processes with unknown characteristics. (Russian)

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), pp. 611–620. *Publ. House Czech. Acad. Sci., Prague*, 1964.

The author discusses some well-known examples of efficient estimates and obtains such estimates for the unknown parameters a_1 and a_2 defined by the model $E(Y_i) = x_{i-1} + a_1 + ia_2$ $(i = 1, \cdots, n)$, where the Y_i's are independent normal random variables with a common variance and the x_i's are the observed (input) values. These estimates are then used for estimating the optimal control values in a special type of discrete control process.

NUMERICAL METHODS

See also 3445, 3674, 3675, 3676a–b, 3808, 3809a–b, 3846, 3883, 3892, 4236, 4282, 4637.

★Numerical methods and programming. I 4172

[Вычислительные методы и программирование. I].

A collection of papers from the Computing Center of Moscow University. Edited by N. P. Trifonov, G. S. Rosljakov, and E. A. Žogolev.

Izdat. Moskov. Univ., Moscow, 1962. 350 pp. 1.30 r.

This collection is in three parts: (I) 13 papers on some questions of a mathematico-computational sort, relating mostly to problems cast as differential equations with finite differences figuring prominently in many of the numerical solution methods; (II) 8 papers describing standard numerical algorithms and programs commonly used for solving typical problems on the STRELA at the Moscow State University Computing Center; and (III) 5 notes on standard routines for the computation of five elementary functions. The book's style is primarily expository with the emphasis on "how to do it", with the more theoretical papers, with a few exceptions, having more of a physics or engineering physics computational, rather than a mathematical, flavor with definitions, theorems, and the like. Much of the work is reasonably standard in computing circles, although the material in Part I seems to be more up to date than in the other parts and is definitely much more sophisticated and mathematical. Most of the papers cite results of computational work done on the STRELA.

The titles of the papers of Part I (and the other parts) describe quite well their contents therefore and, because of the number of papers as well, comments will be brief. B. M. Budak and A. D. Gorbunov, "On Multipoint Difference Methods for the Solution of the Cauchy Problem" for the equation $y' = f(x, y)$, discuss and present in the form of theorems questions of convergence and bounds on errors in the use of these methods (cf. P. Henrici [*Discrete variable methods in ordinary differential equations*, Wiley, New York, 1962; MR **24** #B1772], with this and part of the following two papers). N. S. Bahvalov, "On the Accumulation of Computational Errors in the Numerical Solution of Differential Equations", sketches error estimation procedures for the numerical solution of the Cauchy problem for ordinary differential equations, a two-point boundary-value problem, and the one-dimensional heat diffusion problem. In his second paper, "On the Determination of the Initial Step and an Estimate of the Principal Error Term in Numerical Integration with Automatic Step Selection", Bahvalov applies this type of analysis to the Cauchy problem for ordinary differential equations with particular interest in the use of one-step methods such as those of Runge-Kutta type. N. M. Korobov, "On an Application of Number-Theoretic Grids", is concerned with the evaluation of multiple integrals of periodic and non-periodic functions by finite sums of the integrand evaluated at non-uniformly spaced points determined by number-theoretic considerations which enhance the reduction of the order of the truncation error. Numerical results with several examples in 4 dimensions with a method of non-uniform nets and a method of "optimal coefficients" are compared with Monte Carlo computations.

A. B. Bakušinskiĭ and V. K. Vlasov, "Computation of

Exciton Energy Levels with the Aid of a Continuum-dimensional Integral", are concerned with the application of concepts of M. Kac [Proc. Second Berkeley Sympos. Math. Statist. and Prob. (1950), pp. 189–215, Univ. California Press, Berkeley, Calif., 1951; MR 13, 568] and R. P. Feynman [Rev. Modern Phys. 20 (1948), 367–387; MR 10, 224] to the estimation of the lower quantum-mechanical energy levels of exciton (of interest in the study of semiconducting crystals). Monte Carlo methods to obtain random paths for Feynman integrals are used. Details of the method and program as well as numerical results are given. In a second paper, "On a Method of Numerical Solution of the Dirichlet Problem for Laplace's Equation", they apply an approximation to some old formulas of Krylov and Bogoljubov [Dokl. Akad. Nauk SSSR A 1929, 283–288] which solve the interior and exterior Dirichlet problems where the boundary is a smooth convex curve. Some numerical results on examples with circular and elliptical boundaries with relatively simple boundary functions were obtained on a STRELA computer and are reported in the paper. (See also L. V. Kantorovič and V. I. Krylov [*Approximate methods of higher analysis* (Russian), third edition, GITTL, Moscow, 1950; MR 13, 77; English transl., Interscience, New York, 1955; MR 21 #5268] for a very similar but more detailed description of the same method.)

R. M. Džabar-zade, "The Schwarz Alternating Method for the Solution of the Dirichlet Problem for Nonlinear Equations", establishes the validity of the method for the sum of two regions, and then applies some results of Motzkin and Wasow [J. Math. and Phys. 31 (1953), 253–259; MR 14, 693] to the question of difference equation analogues of the problem, closing with an application to a system of Monge-Ampère type arising in weather prediction. The paper is thoroughly mathematical with no numerical results. N. P. Židkov, A. A. Kornelčuk, A. L. Krylov, and S. B. Mostinskaja, in "Plane-Parallel Flow of a Viscous Fluid Between Rotating Cylinders" considering the cylinders to be infinite in the axial direction, introduce finite-difference approximations to the Navier-Stokes equations which are to be solved by the "metod progonki" (sweep method, or driving-through method) [see Berezin and Židkov, *Computational methods* (Russian), Vol. 2, Fizmatgiz, Moscow, 1959; MR 22 #12685]. Some STRELA-obtained work is discussed. I. Ju. Brallovskaja and L. A. Čudov, in "The Solution of Boundary Layer Equations by Difference Methods", apply standard techniques to a computationally relatively difficult (because of a boundary condition at infinity) problem and present the most extensive numerical results in the entire book.

S. M. Belonosov, A. P. Pavlenko, B. M. Pavlov, and G. S. Rosljakov, in "A Transverse Blow on a Membrane with a Circular Hole", present primarily an engineering type of paper featuring the basic partial differential equations describing the transverse wave motions, the equations of the characteristics, numerical results, diagrams and graphs. E. A. Žogolev, N. P. Trifonov, and D. N. Šahsuvarov, "Computation of Electromagnetic Fields in Laminar Media", investigate the steady field of a dipole in a sheaf of a homogeneous, isotropic, flat plates of varying thickness. The solution involves extensive calculation of infinite integrals whose integrands contain Bessel functions. Derivations, some description of the program, numerical results, graphs, and discussion are given. A. G. Svešnikov, I. P. Kotik, and Ju. S. Černyšev, "On a Method for Calculating the Matchings of Plane Waveguides", are concerned with numerical methods for solving Maxwell's equations with boundary conditions for radio waves traveling in a region determined by two semi-infinite waveguides in the shape of rectangular parallelepipeds joined by a piecewise smooth non-regular coupler. The technique is to use essentially a variation-of-parameters method to determine ordinary differential equations for the longitude varying amplitudes of the component waves. Again, some numerical results are cited. V. V. Voevodin in the final paper of this section, "Computation of the First Eigenfunction and Eigenvalue of the Hill Operator", is concerned with the equation

$$y'' + (\lambda - 2\phi(Z))y = 0,$$

where ϕ is given as a convergent Fourier cosine series simplified for computation purposes to only three terms, leading to an infinite positive definite symmetric matrix with only seven centrally clustered non-vanishing diagonals, which is truncated to one of 19th order for computation.

Part II concerns descriptions of standard algorithms for determining roots of polynomials, determining the characteristic polynomial of a matrix, determining the eigenvalues and eigenvectors of a symmetric matrix by the Jacobi rotation method, integration of ordinary differential equations by the Runge-Kutta method, and, for those of second order, by Störmer's method, interpolation and numerical differentiation, Aitken interpolation, and the computation of Bessel functions.

Part III deals with standard algorithms for computing e^x, $\ln x$, $\sin x$, $\tan x$, and $\arcsin x$, essentially by approximations using Chebyshev polynomials rather than Taylor series to economize on the number of terms needed.

M. L. Juncosa (Santa Monica, Calif.)

Henrici, Peter 4173

★**Elements of numerical analysis.**

John Wiley & Sons, Inc., New York-London-Sydney, 1964. xv + 328 *pp.* $8.00.

This book marks a new level of excellence for introductory texts in numerical analysis. One reason for this is that the author does not try to squeeze in a large number of techniques, but rather takes a few selected topics and studies them with care and in some depth and detail. One may perhaps quibble with the particular selection, but this approach is especially sound in numerical analysis. More fundamental, however, is that the development is placed on scientific and mathematical foundations. Thus a clear distinction is made between algorithms and things we know about them and, more generally, between things we can prove and things we suspect are true.

It is significant that the first section is entitled "What is numerical analysis?". The author obviously believes that it is a science and not an art. He notes that this is not generally the impression given by many otherwise excellent texts and by many instructors who are not primarily numerical analysts. Nor is this belief widespread among mathematicians. Thus a major contribution of this book is to go down toward the foundations that this science must have. Few mathematicians or even numerical analysts seem to be aware of how deep these foundations are or how far we are from them. The author points out

the gross inadequacy of classical and modern mathematics to describe many phenomena in computation. Such fundamental things as stability, conditioning, error propagation and numerical convergence are still not well-defined and hence not understood.

In spite of the fact that this book is entitled "elements", it reaches the frontiers of knowledge with supriaing frequency. This is not done artificially and it is symptomatic of the youth of this science that so many basic, but unanswered, questions present themselves in an elementary text. The author has exploited this fact to present "research problems" at the end of some chapters. A reasonably bright student can actually explore the frontiers of knowledge and gain a taste of the excitement of research. One can only regret that there are not more of these problems. There is also some recent material in the text. Such things as Romberg integration, Müller's method, round-off propagation, Steffensen iteration and the QD algorithm are fitted naturally into the presentation.

In view of the above discussion, one wonders if the prerequisites suggested in the preface are adequate. The development does not depend on any body of material beyond the suggested analytical geometry, calculus and differential equations (though Dedekind cuts are mentioned near the end). However, the student must have enough maturity to handle the concepts of limit and convergence from the beginning.

Among the special features of this book is the widespread and natural use of extrapolation to the limit. This is well done and is placed in its proper perspective. This reviewer heartily applauds the deëmphasis of the difference calculus. It is used only where it is useful and natural, which is to say, not too often. Some authors tend to develop this calculus for its own sake, far beyond the point of usefulness or interest span of the students. The treatment of differential equations is made entirely with Taylor's series. Finally, the author discusses and encourages the experimental study of numerical analysis. This approach is in disrepute among mathematicians, but so little is known about numerical analysis that it is essential to the rapid development of this science. He notes that this is a standard tool in many sciences. Indeed, when a patient takes a drug, no one can prove it will not kill him, one can merely point to the fact that it did not kill the first 1000 people to take it.

For use as a text, the exposition is generally clear and well motivated. There are frequent pertinent examples. There is a large number of problems in addition to the "research" problems. There is an adequate index and bibliography. The book has a pleasant appearance, good figures and the usual number of misprints. The quality of printing is less than one would expect from this publisher. There are several instances in the reviewer's copy of print showing through the back of a page to an objectionable extent and there is an instance of badly broken type on page 188.

A brief description of the contents follows. The introduction contains three chapters. The second presents an elementary account of the properties of complex numbers, polynomials in the complex field and the complex exponential function. The third considers first-order difference equations.

Part One—Solution of Equations—contains five chapters. Chapter 4 considers one equation in one unknown and presents the method of successive substitutions, Newton's method, Steffensen's method and related topics. The next chapter considers systems of equations and the development of the material in parallel with Chapter 4 is well done. Contraction mappings are introduced to discuss successive substitutions. Chapter 6 considers linear difference equations of second order in detail and then neatly extends the results to nth-order systems. Some instructors will find more material on difference equations in this book than they would want to present in a course. The next two chapters present two methods for solving polynomial equations. The first, Bernoulli's method, is analysed in detail. The second, the QD algorithm, seems out of place. Not that it is unimportant, but the author simply cannot analyse it at the level of this book. Although proofs of stated facts are carefully referenced, it does go counter to the general philosophy of the book. The author feels that the algorithm is important enough to warrant its presentation even though its theoretical background cannot be fully exposed. This material illustrates vividly the closeness of the frontiers of numerical analysis. This chapter also discusses briefly the fusing of two (or more) algorithms to obtain an algorithm which is efficient for a large class of problems. Such fusing deserves more attention in numerical analysis.

Part Two—Interpolation and Approximation—considers interpolation by polynomials and approximation of derivations, integrals and differential equations. Chapter 9 considers classical interpolation theory, and though a deep analysis is not possible at this level, the possible pitfalls of interpolation by polynomials of high degree are pointed out. One wonders why a better reference was not suggested for further reading on this topic. It is refreshing to see an author differentiate between a polynomial and its representations. The next two chapters develop various methods of computing interpolating polynomials, using either ordinates or differences. There is a nice discussion of throwback. Chapter 11 presents approximations for derivatives and contains a nice presentation of the general method of extrapolation to the limit. The research problem is especially pertinent and is the type of problem which practicing numerical analysts should consider more frequently. Several of the classical integration formulas are derived in Chapter 12 and then two methods, the trapezoidal rule with end correction and Romberg integration, are discussed in detail. The exposition is good. The next chapter develops difference methods for ordinary differential equations using developments in Taylor series. The discussion of the Runge-Kutta method is brief and leaves the wrong impression of the method. The predictor-corrector methods are nicely done. Some of the pitfalls of instability are neatly illustrated by an example.

Part Three—Computation—considers two topics, number representations and their arithmetics and the propagation of round-off error. The characteristics of fixed-point and floating-point computations are discussed in some detail, as well as the effect of rounding errors in each case. The final chapter discusses the two approaches to round-off error analysis, that of finding strict bounds and statistical estimates. Both have conceptual and practical difficulties. The presentation ends with five stimulating examples of the various possibilities in the nature of round-off error propagation.

In spite of the many good qualities of this book, there is a class of potential users (perhaps the majority) who

will not find this book to their taste. Those who want an exposition of "how-to-do-it" rather than "why-it's-done" will perhaps prefer one of the other books available. Those students who intend to study numerical analysis more than superficially will find this book rewarding.

Kronmal, Richard 4174

Evaluation of a pseudorandom normal number generator.

J. Assoc. Comput. Mach. **11** (1964), 357–363.

This is a report on some tests for randomness of pseudorandom normally distributed numbers. Two independent random variables $X_1 = A\cos 2\pi U_2$, $X_2 = A\sin 2\pi U_2$, where $A = |2\log U_1|^{1/2}$, were studied. They are normally distributed with mean zero and variance unity in case U_1 and U_2 are uniformly distributed in (0, 1). The U's were generated by a method suggested by Rotenberg [same J. 7 (1960), 75–77; MR 22 #8642], namely, $U = r_i 2^{-35}$, where

$$(1)\qquad r_{i+1} \equiv (2^n+1)r_i + c \pmod{2^{35}}.$$

After some experimenting, n was taken as 12 for U_1 and 7 for U_2, and every other term in U_2 was discarded. Eight samples of size 10^6 were tested for serial correlation, runs up and down, runs above and below zero, tests for normality, and order statistics with all data duly tabulated. All tests seem adequately satisfied. The generation of one of the X's requires 200 machine cycles.

{The reviewer would like to question the use of the coefficient 2^n+1 in (1). He realizes that the purpose of this coefficient is to cheapen the cost of producing the r's by eliminating a multiplication; but this also may fail to "stir up" adequately the digits of r_i in the production of r_{i+1} in a binary arithmetic unit. Almost any other large coefficient would be better. If one is going on to calculate X_1 and X_2, one extra multiplication of 14 cycles is almost negligible.}

Elliott, David 4176

The evaluation and estimation of the coefficients in the Chebyshev series expansion of a function.

Math. Comp. **18** (1964), 274–284.

The efficient computation of the coefficients a_n in the Chebyshev series expansion $f(x) = \sum' a_n T_n(x)$ is often easier if there is prior knowledge of their behaviour with increasing n. The author shows how such knowledge may be obtained for certain classes of functions by studying a contour integral definition of a_n. His estimates are supported by examples of (i) a function with poles in the complex plane, (ii) an entire function, (iii) a function regular except at $x = \pm 1$, and (iv) a function with a branch point on the real axis.

Jaech, J. L. 4177

A note on the equivalence of two methods of fitting a straight line through cumulative data.

J. Amer. Statist. Assoc. **59** (1964), 863–866.

Author's summary: "When measurements are made on the same experimental item at successive stages of an experiment, the experimental errors include components which are cumulative in nature, and are hence not independent. This dependence may be removed by using incremental changes in the experimental item as the yield variable, and then using a weighted least squares approach to estimate the parameters of the model, assumed to be linear. Alternately, the original cumulative data may be used directly, and Aitken's method of weighted least squares applied to obtain the parameter estimates. These estimates are shown to be identical."

G. Elfving (Helsinki)

Fisher, Donald D. 4178

Minimum ellipsoids.

Math. Comp. **18** (1964), 669–673.

Author's introduction: "A well-known statistical problem is to determine an ellipsoid R_S^e in E_n which contains a certain fraction of the points from a set S. Here we use the word 'contains' to mean that a point $p_i \in S$ is either in the interior or on the surface of the ellipsoid R_S^e. Although the determination of R_S^e is easy computationally, the determination of the ellipsoid of minimum volume, say, which contains all the points of S is quite difficult. In this note we give a method for determining ellipsoids satisfying a certain minimum property and compare these with ones obtained by statistical methods."

Wetterling, W. 4180

Anwendung des Newtonschen Iterationsverfahrens bei der Tschebyscheff-Approximation, insbesondere mit nichtlinear auftretenden Parametern. II.

Math.-Tech.-Wirtschaft **10** (1963), 112–115.

The author gives further applications of his adaptation of Newton's method to the Čebyšev approximation of a function $f(x)$ by a family $F(x, \mathbf{a})$ (where $\mathbf{a}$ is a real n-vector) [see I. Teil, Math.-Tech.-Wirtschaft 10 (1963), 61–63; MR 28 #704]. The case when $F(x, \mathbf{a})$ is a family of rational functions is discussed in some detail. One instance of an exponential polynomial family, $F(x, \mathbf{a}) = a_1 e^{a_2 x^2} + a_3$, and two instances of a function $f(x, y)$ approximated by families $F(x, y, \mathbf{a})$ of quadratic polynomials, are briefly worked out. Each method is accompanied by a numerical example.

Hsieh, H. C. 4181

An on-line identification scheme for multivariable nonlinear systems.

Computing Methods in Optimization Problems (*Proc. Conf., Univ. California, Los Angeles, Calif.*, 1964), *pp.* 193–210. *Academic Press, New York*, 1964.

Author's summary: "The multivariable nonlinear system considered here is assumed to be characterized by a truncated functional power series. The system is to be identified under normal operating conditions. Least square error criterion is used to estimate the system weighting function matrix and a steepest descent method is employed for solving this problem. A recursive estimation scheme is devised for up-dating its estimation. An 'adjoint space approach', which has the advantage of reducing the dimensionality of the identification problem is explored."

★Numerische Methoden der linearen Algebra.

Mathematik für Naturwissenschaft und Technik, Band 10.

VEB Deutscher Verlag der Wissenschaften, Berlin, 1964. 771 *pp.*

This is a translation of the second edition. The first edition appeared in 1960 [*Computational methods of linear algebra* (Russian), Fizmatgiz, Moscow, 1960]; the second in 1963 [second, augmented edition, Fizmatgiz, Moscow, 1963; MR 28 #4659]; and an English translation of the first appeared also in 1963 [Freeman, San Francisco, Calif., 1963; MR 28 #1742]. By contrast with the English translation, this translation into German is excellent. Clearly the translator understands the subject as well as the language.

A six-page index has been added. The bibliography has been rearranged, names given in Cyrillic in the original and listed separately are here transliterated and placed accordingly. Some errors in the bibliography that remained in the second edition are corrected, and throughout the proofreading has been most painstaking. It is regrettable that not more English translations are of this quality.

A. S. Householder (Oak Ridge, Tenn.)

Bittner, L. 4183

Über ein mehrstufiges Iterationsverfahren zur Lösung von linearen Gleichungen.

Numer. Math. **6** (1964), 161–180.

For solving the system $Ax = y$, the iteration

$$x_n = \sum_1^q C_k x_{n-k} + \sum_1^q D_k(Ax_{n-k} - y)$$

is considered, with special attention to the case where C_k and D_k are polynomials in A. The fundamental lemma states that convergence for arbitrary initial x_i occurs when the determinant of $-\lambda^q I + \sum \lambda^k (C_{q-k} + D_{q-k}A)$ vanishes for no λ with $|\lambda| \geq 1$. The author obtains an estimate of error of a given iterate, and applies the method to the solution of nonlinear systems.

Fiedler, M.; Pták, V. 4184

On aggregation in matrix theory and its application to numerical inverting of large matrices.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. 11 (1963), 757–759.

The authors describe some methods of reducing the problem of inverting a large matrix to the inversion of a smaller one. These methods can be applied to the inversion of badly conditioned Leontiev matrices.

Let $N = N_1 \cup \cdots \cup N_r$ be a decomposition of the numbers $1, \cdots, n$, where N_i has n_i members. If A is an (n, n) matrix, then $c(A)$ is the (r, r) matrix whose i, k element is $(1/n_i n_k) \sum_{p \in N_i, q \in N_k} a_{pq}$. The summation operator $s(A)$ is defined like the contraction operator $c(A)$, omitting the factor $1/n_i n_k$. $\mathscr{L}$ denotes the set of all (n, n) matrices whose elements are constant on each block $N_r \times N_s$.

The main result proved is that if H and S are two (n, n) matrices, H being non-singular and $S \in \mathscr{L}$, then $H - S$ is non-singular if and only if the (r, r) matrix $E - s(H^{-1})c(S)$ is non-singular, and in this case,

$$(H-S)^{-1} = H^{-1} + H^{-1}BH^{-1},$$

where $c(B) = c(S)[E - s(H^{-1})c(S)]^{-1}$, $B \in \mathscr{L}$, and E is the identity matrix.

This and some related results are proved by applying the following lemma. Let H be a non-singular (r, n) matrix and U', V two (r, n) matrices. Then

$$\det(H - U'V) = \det H \det(E - VH^{-1}U'),$$

and

$$(H - U'V)^{-1} = H^{-1} + H^{-1}U'(E - VH^{-1}U')^{-1}VH^{-1},$$

provided $(E - VH^{-1}U')$ is non-singular.

A Leontiev matrix x has the form $E - A$, where A has non-negative elements and row sums smaller than 1. To apply the theorem given above, choose $S \in \mathscr{L}$ (with suitable N_i) such that $Y = A - S$ is small enough (according to the norm $\|Y\| = \max_i \sum_k |y_{ik}|$), and take $H = E - Y$. If $E - A$ is badly conditioned, i.e., $\|A\|$ is not much less than 1, then H will be better conditioned, and the difficulties of inverting an ill-conditioned matrix are transferred to a smaller matrix. *A. M. Duguid* (London)

Hageman, Louis A.; Varga, Richard S. 4185

Block iterative methods for cyclically reduced matrix equations.

Numer. Math. **6** (1964), 106–119.

Bei Anwendung des Differenzenverfahrens auf Randwertaufgaben für elliptische Differentialgleichungen zweiter Ordnung erhält man gewöhnlich lineare Gleichungssysteme der Form

$$(*) \qquad \begin{bmatrix} I_{1,1} & -B_{1,2} \\ -B_{2,1} & I_{2,2} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} k_1 \\ k_2 \end{bmatrix},$$

wobei $I_{1,1}$ und $I_{2,2}$ Einheitsmatrizen bedeuten. Bei einem solchen Gleichungssystem kann man der Vektor x_1 auch als Lösung des reduzierten Systems

$$(I_{1,1} - B_{1,2}B_{2,1})x_1 = k_1 + B_{1,2}k_2$$

und anschliessend x_2 aus (*) berechnen. Im Falle der Differenzengleichungen enthält dieses reduzierte System

etwa halb so viel Unbekannte, es kann ohne Matrizenmultiplikation aufgestellt werden, und das Gauss-Seidel-Verfahren konvergiert für das reduzierte System schneller [siehe Referent, Z. Angew. Math. Mech. **34** (1954), 241–253; MR **16**, 406; R. S. Varga, *Matrix iterative analysis*, Prentice-Hall, Englewood Cliffs, N.J., 1962; MR **28** #1725]. Für Differenzenverfahren der erwähnten Art (*) sind verschiedene verbesserte Iterationsverfahren entwickelt worden, z.B. die "successive over-relaxation iterative method" [S. P. Frankel, MTAC **4** (1950), 65–75; MR **13**, 692; D. M. Young, Trans. Amer. Math. Soc. **76** (1954), 92–111; MR **15**, 562] und die "cyclic Chebyshev semi-iterative method" [G. H. Golub und R. S. Varga, Numer. Math. **3** (1961), 147–156; MR **26** #3207; ibid. **3** (1961), 157–168; MR **26** #3208], gekoppelt mit "block or multi-line techniques". Die Verfasser definieren nun diesen Verfahren zugehörige "induzierte" Iterationsverfahren für das reduzierte System und untersuchen deren Konvergenz. Die zugehörigen Iterationsmatrizen besitzen einen kleineren Spektralradius. Im Falle eines Modellproblems wird der erforderliche Rechenaufwand genauer verglichen. Numerische Beispiele bestätigen, dass die induzierten Verfahren weniger Zeit und Iterationsschritte benötigen.

Kublanovskaja, V. N. 4186

A numerical scheme for the Jacobi process. **(Russian)**

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 732–733.

The author gives descriptions of algorithms, based on sequences of right multiplications of A by two-dimensional rotation matrices, $T^{(k)}$, which generate sequences of matrices $A^{(k)}$ such that $A^{(k)'}A^{(k)}$ tends to a diagonal matrix and such that $T_k = \prod_0^k T^{(i)}$ tends to the modal matrix of $A'A$. Thus a solution of the complete eigenvalue problem for $A'A$ is obtained without actually forming $A'A$. Acceleration of the process is discussed, and an application to the orthogonalization, with respect to a given metric, of a system of vectors, is mentioned.

Lietzke, Marjorie P.

A comparison of several methods for inverting large symmetric positive definite matrices.

Math. Comp. **18** (1964), 449–456.

The $n \times n$ matrices of diagonal 2's and super- and sub-diagonal -1's and a few of its low powers are inverted numerically for various n in order to compare four methods of inversion: Gauss-Jordan, Choleski, congruent transformation, and rank annihilation. The Gauss-Jordan reduction seems to fare somewhat the best.

H. S. Wilf (Philadelphia, Pa.)

Yamashita, Shin-ichiro 4188

Numerical solution of algebraic equations.

Information Processing in Japan **2** (1962), 13–16.

This paper first appeared in Japanese in the Journal of the Information Processing Society of Japan **2** (1961), no. 5, 249–252. The version reviewed in the following has obscurities but is still fairly easy to read.

A part of the paper considers a method for computing roots of polynomials. The author's description of the method is as follows: $f(x) = (x+p_n)Q(x) + R$, $Q(x) = (x+p_n)Q'(x) + S$, $p_{n+1} = p_n + R/S$, convergence test: $|R/p_{n+1}S|$. Here $f(x)$ is the given polynomial but the author does not define or discuss any other symbols. He omits any discussion of procedure or of what he means by convergence test. No derivation is given nor is an example worked out. The method appears to be a variant of Hitchcock's method designed to extract linear factors from $f(x)$.

The remainder of the paper is concerned with polynomials having ill-conditioned roots. The paper calls such polynomials "bad-charactered". Two examples are given to illustrate the difficulties in computing such roots, using a fixed number of digits.

Nothing new is presented in the discussion of ill-conditioned roots. A more thorough discussion of the problem is given, for example, by Wilkinson [Numer. Math. **1** (1959), 150–180; MR **22** #321].

{The paper suffers from a lack of preciseness. Statements occur which vary from the ambiguous to the incorrect.}

Kowel, Stephen T. 4189

Absolute iteration and the solution of transcendental equations.

J. Franklin Inst. **278** (1964), 210–218.

To solve the equation $\theta(x) = 0$, it is proposed that the equation be rewritten in the form $f(x) = g(x)$ and the iterative scheme $f(x_{n+1}) = g(x_n)$ be used. Under appropriate conditions it is shown that a sufficient condition for convergence is $f'(x) > g'(x)$ for x in a neighborhood of a solution. The ratio $f'(x)/g'(x)$ is a measure of the rapidity of convergence. Some examples are given.

L. W. Ehrlich (Silver Spring, Md.)

Našul', A. B. 4190

Improving the convergence of methods of successive approximation for linear equations. **(Russian)**

Dokl. Akad. Nauk SSSR **158** (1964), 279–280.

The author describes a method for improving the convergence of the process of successive approximation $x_n = Bx_{n-1} + b$ for the solution of linear algebraic equations $x = Bx + b$. Noting that, for $n = 2^{s-1}$,

$$U_n \equiv (I + B + B^2 + \cdots + B^{n-1}) =$$

$$(I + B^{2^{s-2}})(I + B^{2^{s-3}}) \cdots (I + B^2)(I + B),$$

the author suggests the use of the iteration process $x_{2^{s-1}} = B^{2^{s-1}}x_0 + U_{2^{s-1}}b$ in which $U_{2^{s-1}}$ and $B^{2^{s-1}}$ are successively computed by the formulas

$$U_{2^{s-1}} = (I + B^{2^{s-2}})U_{2^{s-2}}, \quad U_1 = 1, \quad B^{2^{s-1}} = (B^{2^{s-2}})^2.$$

In this way, s steps with the improved process are equivalent to $n = 2^{s-1}$ steps with the ordinary process.

W. V. Petryshyn (Chicago, Ill.)

Obreškov, Nikola 4191

On the numerical solution of equations. **(Bulgarian. French summary)**

Annuaire Univ. Sofia Fac. Sci. Phys. Math. Livre 1 Math. **56** (1961/62), 73–83 (1963).

In the first part of this paper the author discusses the

Laguerre method for determining a root of an algebraic equation of nth degree, $f(x)=0$, with n real roots. Consider a sequence of successive approximate values $a_1, a_2, \cdots$ of a simple root α, obtained by the Laguerre method. It is known that in this case the process of approximation is of third order. The author shows that if α is a root of multiplicity $p>1$, then the Laguerre method gives only a first-order process. For improving the order of approximation the author modifies the Laguerre method:

$$a_{n+1} = a_n - \frac{nf(a_n)}{f(a_n) \pm \sqrt{((n/p-1)[(n-1)f'(a_n)^2 - nf(a_n)f''(a_n)])}}$$

and shows that this gives a third-order process.

In the second part of the paper the author makes similar considerations in the case of Newton's method. He shows that if α is a root of multiplicity $p>1$, then the Newton method represents a first-order procedure. In this case he presents a modification of Newton's method:

$$a_{n+1} = a_n - \frac{2pf(a_n)f'(a_n)}{(p+1)f'(a_n)^2 - pf(a_n)f''(a_n)},$$

which is a third-order process of approximation. Finally, he gives a generalization of the Chebyshev method.

Spiridonov, V. 4196

On a quadrature formula of S. N. Bernstein. (Russian)

C. R. Acad. Bulgare Sci. **17** (1964), 339–342.

The concern here is with quadrature formulas

$$\int_{-1}^{1} f(x)\,dx \doteq \sum_{i=1}^{l-1} p_i[f(x_i)+f(-x_i)] + p_0 f(0)$$

having the following properties: (i) they are exact for all polynomials of degree $2l-1$; (ii) all coefficients p_i are positive; (iii) the abscissas x_i are rational numbers in $[-1,1]$ which can be represented by fractions with denominators not exceeding 10. S. N. Bernšteĭn [*Collected Works* (Russian), Vol. II, pp. 228–230, Izdat. Akad. Nauk SSSR, Moscow, 1954; MR **16**, 433] showed that such formulas exist if $l \le 7$, but do not exist if $l \ge 9$. The case $l=8$ remained undecided. The author now settles this case in the negative.

Walter Gautschi (Lafayette, Ind.)

Adrianova, L. Ja. 4197

A strict error bound for the integration of differential equations by Störmer's method. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **19** (1964), no. 3, 5–17.

The author deals with systems of the form $d^2x/dt^2 = f(t,x)$, $x(t_0)=x_0$, $x'(t_0)=x_0'$, where x and $f(t,x)$ are real vectors from E_n and t is a scalar variable. The object is to get an a priori estimate for the truncation error of Störmer's method. To this end she uses the method of Lozinskiĭ [Izv. Vysš. Učebn. Zaved. Matematika **1958**, no. 5 (6), 52–90; errata, ibid. **1959**, no. 5 (12), 222; MR **26** #3191] which was used by Lozinskiĭ for deriving a priori estimates for the truncation error when solving systems of the first order by the Adams method. The theorem proved by the author is too lengthy to be stated here.

M. Zlámal (College Park, Md.)

Axelsson, Owe 4198

Global integration of differential equations through Lobatto quadrature.

Nordisk Tidskr. Informations-Behandling **4** (1964), 69–86.

Zur numerischen Integration von $y'=f(x,y)$, $y(-1)=y_0$ im Intervall $-1\leq x\leq 1$ wird ein System von nichtlinearen Gleichungen

$$y_{i,n}=y_0+\sum_{k=1}^{n}A_{i,k}^{(n)}f(x_{k,n},y_{k,n})\qquad (i=1,2,\cdots,n)$$

gelöst. Die $A_{ik}^{(n)}$ werden durch Integration von Interpolationsformeln gewonnen; ihre Matrix ist wertemäßig nahezu eine Dreiecksmatrix; für große n streben die Elemente oberhalb der Hauptdiagonalen gegen 0; das nichtlineare Gleichungssystem ist daher bequem mit Iterationen zu behandeln. Nimmt man als Teilpunkte $x_{k,n}$ die Nullstellen von $P_n(x)-P_{n-2}(x)$ (mit $P_n(x)$ als Legendresche Polynome), so wird

$$\operatorname*{Max}_i |y_{i,n}-y(x_{i,n})|\to 0\quad \text{für } n\to\infty$$

gezeigt. Aus den Werten $f(x_{i,n},y_{i,n})$ für $i=1,\cdots,n$ werden Approximationspolynome $y_n(x)$ konstruiert, die in $\langle -1,1\rangle$ gleichmäßig gegen $y(x)$ konvergieren. Speziell am Intervallende ist der Fehler verhältnismäßig klein.

Es wäre schön gewesen, wenn der Autor bei seinen Sätzen die Voraussetzungen angegeben hätte, die er beim Beweis gelegentlich braucht, wie z.B. Beschränktheit vom f_{yy}. In der Einleitung wird gesagt: Die Stellen des maximalen Fehlers sind bekannt; auch hier wäre die Angabe der speziellen Voraussetzungen, unter denen dies gilt, sehr erwünscht. *L. Collatz* (Hamburg)

Krylov, V. I.; Monastyrnyi, P. I. 4199

The sweep method for solving a fourth-order differential equation. (Russian)

Vesci Akad. Navuk BSSR Ser. Fiz.-Tèhn. Navuk **1964**, no. 2, 5–11.

The authors consider the fourth-order differential equation

$$(1)\qquad y^{(4)}+\sum_{k=1}^{4}P_k(x)y^{(4-k)}=F(x)$$

subject to the boundary conditions

$$(2)\qquad \sum_{k=1}^{4}a_{ik}y^{(4-k)}(a)=A_i,\qquad \sum_{k=1}^{4}b_{ik}y^{(4-k)}(b)=B_i\qquad (i=1,2).$$

The method of solution discussed here derives from the observation that the general solution of (1), subject to the boundary conditions at $x=a$, coincides with the general solution of

$$(3)\qquad y''-p(x)y'-q(x)=r(x),$$

where p, q, r are obtainable from a nonlinear Cauchy problem with initial data at $x=a$. The desired solution of (1), (2) may then be found by solving a Cauchy problem for (3), with initial data given at $x=b$. This data depends on the values at $x=b$ of p, q, r and their derivatives. Possible singularities in the first Cauchy problem can be handled by working with new dependent variables defined by $p(x)=\tan\alpha(x)$, $q(x)=\tan\beta(x)\sec\alpha(x)$, $r(x)=r_1(x)\sec\alpha(x)\sec\beta(x)$. *Walter Gautschi* (Lafayette, Ind.)

Meshaka, P. 4200

Deux méthodes d'intégration numérique pour systèmes différentiels.

Rev. Française Traitement Information (Chiffres) **7** (1964), 135–148.

First, a stable, implicit, linear 5-step method, $p=k=5$, is suggested, the characteristic feature of which is that no values of y' need to be stored, $\sigma(\zeta)=\zeta^5$. (The 4-step Adams-Moulton method, $\rho(\zeta)=\zeta^4-\zeta^3$, has a similar merit, and the reviewer cannot find in what respect it is inferior to the author's method.) Next, an implicit, stable method for systems of the first order is suggested, which requires the computation of y''. The corrector is based on the relation

$$7y_{n+1}=(8y_n-y_{n-1})+2h(y'_{n+1}+2y_n')+2h^2y_n''+O(h^5).$$

It is not mentioned why this particular formula is preferable to other, more accurate, formulas based on essentially the same information. *G. Dahlquist* (Stockholm)

Pelczar, A. 4201

On a modification of the method of Euler polygons for the ordinary differential equation.

Ann. Polon. Math. **15** (1964), 195–202.

To solve the ordinary differential equation

$$(1)\qquad y'=f(x,y),\qquad y(a)=c,\qquad a\leq x\leq\xi,$$

the author constructs a sequence of functions which converge to its solution. Let $Z_0(x,\xi)=c$. Let $Z_n(x,\xi)$, $n=1,2,\cdots$, be the Euler polygon constructed for the interval (a,ξ) and the division of this interval into points

$$a_j=a+\frac{j}{n}(\xi-a),\qquad j=0,1,\cdots,n.$$

Define $\phi_n(x)=Z_n(x,x)$, $n=0,1,2,\cdots$. Provided that $f(x,y)\in C$ and is bounded in $a\leq x\leq b$, $|y-c|\leq M$, where $b-a<1$, and a unique solution $y(x)$ to (1) exists in $[a,b]$, then the sequence $\phi_n(x)$ converges uniformly to $y(x)$. Further theorems are given which give conditions under which the derivatives of $\phi_n(x)$ converge uniformly to $y^{(n)}(x)$ in $[a,b]$. *A. O. Garder, Jr.* (St. Louis, Mo.)

v. Sanden, H. 4202

Eine Bemerkung zur numerisch-tabellarischen Integration gewöhnlicher Differentialgleichungen nach Runge-Kutta.

Z. Angew. Math. Mech. **43** (1963), 561.

The presentation of the classical Runge-Kutta method in a course is discussed. The author first gives a short proof that the error in one step is $O(h^5)$ for $y'=f(x,y)$, $y(0)=0$, if $f(0,0)=0$. In the extension to the general case it is tacitly assumed that the relation $y(h)=z(h)+rh$ holds exactly for the approximate solutions of the problems $y'=r+f(x,y)$, $y(0)=0$ and $z'=f(x,z+rx)$, $z(0)=0$. This is correct, though not self-evident. *G. Dahlquist* (Stockholm)

Veliev, M. A. 4203

A study of the stability of the Bubnov-Galerkin method for non-stationary problems. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 16–18.

For the equation $Au=f$, where A is a positive definite operator defined on a Hilbert space, Mihlin proved stability of the Ritz method provided the system of coordinate functions is "strongly minimal" [same Dokl. **135** (1960), 16–19; MR **27** #4362; Vestnik Leningrad. Univ. **16**

(1961), no. 13, 40–51; MR 25 #2698]. In the present paper the author announces analogous results for the Bubnov-Galerkin method when applied to the Cauchy problem for the second-order differential equation $Au''(t)+Bu'(t)+Cu(t)=f(t)$ with constant operator coefficients.

Walter Gautschi (Lafayette, Ind.)

Zee, Chong-Hung 4204

On solving second order nonlinear differential equations.

Quart. Appl. Math. **22** (1964), 71–73.

In solving the equation $y''=f(x, y, y')$ by power series using n terms, the author proposes to treat the points at which derivatives are evaluated in the expressions for the remainders of y, y', and y'' as if at all three points the $(n+1)$st derivative of y has the same value. Then if R_{n0}, R_{n1}, R_{n2} are the remainders in the series for y, y', and y'', respectively, we can write

$$R_{n1}=\frac{n+1}{\Delta X}R_{n0}, \qquad R_{n2}=\frac{n(n+1)}{\Delta X^2}R_{n0}.$$

If the three truncated series with remainders are then substituted into the differential equation, it may be solved for the one unknown, R_{n0}. Unfortunately, the author makes no effort to investigate how good this approximation is. It would seem natural to test it on simple equations where remainders are known exactly.

Dynamic programming, invariant imbedding and quasilinearization: Comparisons and interconnections.

Computing Methods in Optimization Problems (Proc. Conf., Univ. California, Los Angeles, Calif., 1964), pp. 135–145. *Academic Press, New York*, 1964.

Authors' introduction: "In this paper we shall treat a simple class of variational problems from three different points of view: quasilinearization, dynamic programming, and invariant imbedding. Our aim is to adumbrate the point of view that leads to the various equations associated with each method. Primary emphasis is upon the computational aspects, though the development of effective numerical schemes requires significant analytical advances. The general theme is the computational solution of nonlinear two-point boundary value problems via a direct assault and via conversions into initial-value problems."

Bhargava, R. D.; Radhakrishna, H. C. 4206

Numerical solution of two-dimensional Laplace's equation.

Proc. Nat. Inst. Sci. India Part A **29** (1963), 283–293.

Green's formula gives a singular linear integral equation from which the boundary values of a harmonic function or its normal derivative can be solved when the boundary values of the other (or of a linear combination of them) are given. The value at an interior point can then be obtained by quadrature. A technique for numerical integration of this equation is applied to a symmetric Dirichlet problem with four arcs in a quadrant.

The numerical aspects of the technique are not extensively discussed. {It is worth mentioning that the integral equation method requires little storage compared to finite-difference methods, and that it can be applied when the boundary conditions are complicated.}

G. Dahlquist (Stockholm)

Zenkin, O. V. 4207

On the relation between the algorithms for constructing solutions of certain equations of parabolic and elliptic types. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 23–26.

The author considers the following boundary-value problem

$$au_t = u_{xx}+u_{yy}+f(x, y), \qquad a>0,$$

when initially $u(x, y, 0)=0$, and when on the boundary $u=0$. The author assumes that the solution is in the form

$$u(x, y, t) = U(x, y)+v(x, y, t),$$

which, when substituted in the original problem, leads to two new boundary-value problems, one determining v, another determining U. The problem for v can be solved in series, but the one for U requires a numerical solution.

The author solves numerically the original problem for $u(x, y, t)$ and the modified problem for $U(x, y)$ using finite differences with the subsequent application of the Gauss-Seidel process. Comparing the two solutions, the author shows that the modified problem needs only half of the number of iterations as compared with the original one.

T. Leser (Aberdeen, Md.)

Bramble, J. H.; Hubbard, B. E. 4208

Approximation of derivatives by finite difference methods in elliptic boundary value problems.

Contributions to Differential Equations **3** (1964), 399–410.

The authors consider the problem of approximating the solution of the Dirichlet problem for

$$Lu \equiv au_{xx}+2bu_{xy}+cu_{yy}+du_x+eu_y+fu = F$$

in a connected region R with smooth boundary C in the (x, y)-plane, where $|b|<a, c$; $f<0$ and the coefficients and data are smooth. Results are obtained for problems in this class which have solutions with bounded fifth derivatives.

A finite-difference analogue $L_hU(p)=F(p)$, where h is the grid size and where p is a point of the difference mesh, is constructed in such a way that L is approximated no worse than $O(h)$ at points near and on the boundary C and $O(h^2)$ in the interior. Then if $e(p)=U(p)-u(p)$ and p and p' are neighboring points with $\overline{pp'}$ the distance from p to p', it is shown that

$$|e|_{R_h} = \max_{p\in R_h}|e(p)| = O(h^2),$$

where R_h is the set of mesh points each having its eight nearest neighbors in R. Also

$$\left|\frac{e(p)-e(p')}{\overline{pp'}}\right| = O(h^2).$$

Using the Laplace operator, an example is constructed to show that a uniform estimate of the latter type cannot hold if the approximation is $O(1)$ on the set of points which have at least one horizontal or vertical neighbor not in R.

At interior points, however, it is further shown that, in

spite of poorer convergence near the boundary, one may still have an approximation of order $O(h^2)$. In fact, if D_h^n is an nth-order difference quotient, it is shown that, at interior points,

$$|D_h^n e(p)| \leq K_n |e|_{B_h} + O(h^2),$$

provided b does not change sign in the region and the coefficients of L and the solution u are sufficiently smooth.

A. O. Garder, Jr. (St. Louis, Mo.)

Johansson, Olov; Kreiss, Heinz-Otto 4209

Über das Verfahren der zentralen Differenzen zur Lösung des Cauchyproblems für partielle Differentialgleichungen. (English summary)

Nordisk Tidskr. Informations-Behandling **3** (1963), 97–107.

Difference methods are investigated for the Cauchy problem for a system of n partial differential equations in s space variables,

$$(*) \qquad \partial u/\partial t = P(u), \qquad u(x, 0) = f(x),$$

$$x = (x_1, x_2, \cdots, x_s) \in R_s, \qquad u = (u_1, u_2, \cdots, u_n) \in S_n,$$

$$Pu = \sum_{i=1}^{s} [\partial_i(A_i(x)\partial_i u) + \tfrac{1}{2}(B_i(x)\partial_i u + \partial_i(B_i(x)u))] + C(x)u,$$

where the $u_i = u_i(x, t)$ are complex-valued. The A_i, B_i, C are complex matrix-valued, twice differentiable, bounded functions of x such that the $A_i^* + A_i$ are positive semi-definite and the B_i are hermitian for all $x \in R_s$. If for all $w \in L_2(R_s)$,

$$\operatorname{Re}(w, Pw) \leq \operatorname{Re}(w, Cw) \leq \delta\|w\|^2,$$

then the solutions of (*) which belong to $L_2(R_s)$, together with their derivatives of second order, satisfy the inequality

$$(**) \qquad \|u(\cdot, t)\| \leq e^{\delta t}\|u(\cdot, 0)\| \qquad (t > 0).$$

Let $P = P_0 + P_1$, where P_0 and P_1 are selfadjoint and anti-selfadjoint operators in $L_2(R_s)$, respectively.

The authors suggest difference methods of the form

$$(I - kQ_0)v(\cdot, t+k) = (I + kQ_0)v(\cdot, t-k) + 2kQ_1 v(\cdot, t),$$

where Q_0, Q_1 are difference operators defined on the grid $\{(\nu_1 h^{(1)}, \nu_2 h^{(2)}, \cdots, \nu_s h^{(s)})\}$ in R_s (ν_i integers) which converge formally to P_0, P_1, when $h = (h^{(1)}, h^{(2)}, \cdots, h^{(s)}) \to 0$. The characteristic requirement of this paper is that there should exist a sequence $S = \{(h_i, k_i)\}_{i=0}^{\infty}$ converging to $(0, 0)$, such that for all $(h, k) \in S$ and for all $t = \nu k$, $\nu = 0, 1, 2, \cdots$,

$$(***) \quad \|v(\cdot, t)\|_h^2 \leq$$
$$K \exp(2\delta t(1 + O(k^2\delta^2)))(\|v(\cdot, 0)\|_h^2 + \|v(\cdot, k)\|_h^2).$$

(The norm $\|\cdot\|_h$ converges to the L_2-norm as $h \to 0$.)

The authors prove a convenient sufficient condition for (***) and apply it to the case where Q_0, Q_1 are the simplest central difference operators consistent with P_0, P_1. If the $A_i(x)$ are hermitian for all x, then (***) holds provided that $k/|h|$ does not exceed a certain bound, otherwise a bound for $k/|h|^2$ is also required. (All $h^{(i)}$ are assumed to be equal.)

Finally, it is remarked that if a first-order term is given in the form $B_i(x)\partial_i u$, then its anti-selfadjoint part, $-\tfrac{1}{2}(B_i\partial_i u) + \tfrac{1}{2}\partial_i(B_i u) = \tfrac{1}{2}(\partial B_i)u$, is a bounded operator which has to be added to C, and hence included in P_0, in order to warrant the validity of (***).

G. Dahlquist (Stockholm)

Kreiss, Heinz-Otto 4210

On difference approximations of the dissipative type for hyperbolic differential equations.

Comm. Pure Appl. Math. 17 (1964), 335–353.

Let $(M_h u)(x) = \sum c_j(x)u(x + jh)$ define an explicit difference operator M_h with bounded, Lipschitz continuous, Hermitian matrix coefficients c_j. Suppose the eigenvalues $\lambda_k(x, \xi)$ of $\sum c_j(x)e^{ij\xi}$ satisfy $|\lambda| \leq 1 - \delta|\xi|^{2r}$, with fixed positive δ and r, and suppose $u(t+h) = M_h u(t)$ approximates some symmetric hyperbolic system with local accuracy $2r-1$ or $2r-2$. Then the author establishes $\|M_h\| \leq 1 + O(h)$ in a norm equivalent to the L_2 norm, so that M_h is stable in L_2. Although simplifications have since been found for the proof, the result itself is the climax of the theory of symmetric hyperbolic difference methods.

Konoval'cev, I. V. 4211

A difference boundary-value problem for a self-adjoint parabolic system. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. 4 (1964), 765–771.

Bounds are derived for the difference solution of the first initial boundary value problem for the parabolic system

$$\frac{\partial u}{\partial t} = \sum_{i=0}^{p} \frac{\partial^{p-i}}{\partial x^{p-i}}\left(a^{(i)}(x, t)\frac{\partial^{p-i}u}{\partial x^{p-i}}\right) + f$$

in $\{x, t : 0 \leq x \leq \varepsilon,\ 0 \leq t < \infty\}$ with

$$u\bigg|_{t=0} = \phi(x), \quad \frac{\partial^k u}{\partial x^k}\bigg|_{x=0} = \psi^{(k)}(t), \quad \frac{\partial^k u}{\partial x^k}\bigg|_{x=\varepsilon} = \chi^{(k)}(t),$$
$$k = 0, 1, \cdots, p-1,$$

which prove that the principle of non-growth mesh ratio is also applicable in this case. The asymptotic behaviour of the solutions for $\varepsilon \to 0$ as well as for $t = \infty$ is considered.

Konovalov, A. N. 4212

Application of the splitting method to the numerical solution of dynamics problems in the theory of elasticity. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. 4 (1964), 760–764.

A finite-difference technique is employed to solve the following dynamical problem in the theory of isotropic elasticity. In the cylinder

$$D = Q \times [0 \leq t \leq T],$$
$$Q = \{[\alpha_1 \leq x_1 \leq \beta_1] \times [\alpha_2 \leq x_2 \leq \beta_2]\},$$

it is required to find the displacement vector $\mathbf{u}(x_1, x_2)$ which (a) is a solution of the equation

$$\frac{\partial^2 \mathbf{u}}{\partial t^2} = \mu\Delta\mathbf{u} + (\lambda + \mu)\operatorname{grad}\operatorname{div}\mathbf{u} + \mathbf{f};$$

(b) at $t = 0$ satisfies the conditions

$$\mathbf{u}(x_1, x_2, 0) = \boldsymbol{\varphi}(x_1, x_2), \qquad \frac{\partial \mathbf{u}}{\partial t}(x_1, x_2, 0) = \boldsymbol{\psi}(x_1, x_2);$$

and (c) attains on the lateral surface S of the cylinder the given value

$$u(x_1, x_2, t)|_S = g(x_1, x_2, t) \qquad (x_1, x_2, t) \in S.$$

A direct method for increased accuracy in solving boundary-value problems for the Helmholtz equation on a grid of points in a rectangle. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 771–773.

This note improves the first author's solution of the Helmholtz equation by the grid method [same Ž. **2** (1962), 418–436; MR **27** #4372] in that, instead of central differences, the formula

$$\varphi(x_{j+1}) - 2\varphi(x_j) + \varphi(x_{j-1}) = \tfrac{1}{12} h^2[\varphi''(x_{j+1}) + 10\varphi''(x_j) + \varphi''(x_{j-1})] + O(h^6)$$

is used to approximate the second derivative in the differential equation and the formula

$$2h\varphi'(x_i) = \varphi(x_{i+1}) - \varphi(x_{i-1}) - \tfrac{1}{3}h^3\varphi'''(x_i) + O(h^5),$$

the first derivative in the boundary conditions. Use of the differential equation eliminates $\varphi'''(x)$. This method yields a higher order of accuracy without complicating the algorithm or increasing the number of arithmetical steps.

R. N. Goss (San Diego, Calif.)

Pavljuk, I. A. 4214

Asymptotic representation of the solution (by the method of lines) of a mixed problem for an hyperbolic equation. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 726–729.

The following mixed problem is considered in the region $0 \le x \le l$, $0 \le t \le L$:

$$(1) \qquad \begin{gathered} \frac{\partial^2 u}{\partial t^2} - b(x, t)\frac{\partial^2 u}{\partial x^2} = f(x, t), \qquad b(x, t) > 0, \\ u(x, 0) = p_1(x), \qquad u_t(x, 0) = p_2(x), \\ u(0, t) = r_1(t), \qquad u(l, t) = r_2(t). \end{gathered}$$

Using the method of lines the author transforms the equation (1) into the system of linear differential equations

$$u_k'' - h^{-2}b_k(t)[u_{k+1} - 2u_k + u_{k-1}] = f_k(t) + O(h^2),$$

where $u_k(t) = u(kh, t)$, $f_k(t) = f(kh, t)$, $b_k(t) = b(kh, t)$ and $k = 0, 1, \cdots, n+1$, $h = l/(n+1)$. By examining the asymptotic form of the solution of this system he derives the asymptotic formula of the form $u(t, h) = A(t)z_1(t, h) + hA(t)z_2(t, h) + O(h^2)$, where $u(t, h)$ is the solution-vector, i.e., the vector whose components are the functions $u_1(t)$, $u_2(t)$, $\cdots$, $u_n(t)$, and $A(t)$ is a certain square matrix and $z_1(t, h)$ and $z_2(t, h)$ certain column-vectors.

M. Zlámal (College Park, Md.)

Strang, Gilbert 4215

Accurate partial difference methods. II. Non-linear problems.

Numer. Math. **6** (1964), 37–46.

Part I appeared in Arch. Rational Mech. Anal. **12** (1963), 392–402 [MR **26** #4489]. Consider the initial-value problem for a quasilinear hyperbolic system

$$(1) \qquad \frac{\partial u}{\partial t} = \sum_{i=1}^{d} A_i(u, x, t)\frac{\partial u}{\partial x_i}, \qquad u(0, t) = u_0(x), \qquad -\infty < x_i < +\infty,$$

and approximate it by a difference approximation which, in its linearized form, is stable in the sense of Lax and Richtmyer. Assuming that (1) has a sufficiently smooth solution $u(x, t)$, the author shows that the solutions of the difference approximation converge to $u(x, t)$. Then he applies this theorem to approximations of the Runge-Kutta and Lax-Wendroff type. *H.-O. Kreiss* (Göteborg)

Tee, G. J. 4216

A new technique for solving elliptic partial differential equations.

J. Soc. Indust. Appl. Math. **12** (1964), 311–347.

By replacing a nine-point difference equation with a pair of equations of the form

$$(1) \qquad \phi_{i,k} = \alpha_{i,k}\phi_{i-1,k} + \beta_{i,k}\phi_{i-1,k-1} + \gamma_{i,k}\phi_{i,k-1} + h^2\delta_{i,k},$$

$$(2) \qquad v_{i,k} = a_{i,k}v_{i+1,k} + b_{i,k}v_{i+1,k+1} + c_{i,k}v_{i,k+1} + \phi_{i,k},$$

the author explores the possibility of approximating the solution of a linear elliptic boundary-value problem by a method of sweeping up and to the right by means of (1) and then down and to the left by means of (2). A large portion of the paper is devoted to the determination of $\alpha, \beta, \gamma, a, b$, and c for various boundary conditions and to various computational considerations. No convergence criteria are established, and the boundary of the region is severely restricted in shape. The method is applied in detail to a specific Dirichlet problem for the Laplace equation on a rectangular region, a problem for which, of course, there is no need for a numerical method.

Wynn, Peter 4217

Partial differential equations associated with certain non-linear algorithms. (German summary)

Z. Angew. Math. Phys. **15** (1964), 273–289.

In this paper are discussed certain algorithms (for example, the qd-algorithm) that relate four quantities connected by rational non-linear relationships and lying at the vertices of a rhombus. When the dimension of this rhombus is made infinitesimally small, these algorithms lead to systems of two simultaneous partial differential equations of the first order. These partial differential equations are derived for the algorithms given here.

The epsilon algorithm is a computational device for the acceleration of the convergence of a slowly convergent sequence. Here it is applied to slowly convergent vector sequences, and ALGOL programs are given for the procedures. *E. Frank* (Chicago, Ill.)

Volkov, E. A. 4221

The method of nets for boundary-value problems with skew and normal derivatives. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **1** (1961), 607–621.

The author considers the numerical solution of

$$\Delta\varphi = f(x_1, x_2), \qquad (x, y) \in G,$$

$$\frac{\partial\varphi}{\partial\rho} = \alpha, \qquad (x, y) \in \partial G.$$

He assumes that G is simply connected and contains the origin. Also, he assumes that ∂G, f, $\alpha(s)$, and $\rho(s)$, where s is the arc length on ∂G, satisfy regularity conditions and that $\varphi \in C^4(G^-)$. He imposes a square lattice on the region and divides the grid points in G into interior grid points D and points D_0 near the boundary. His difference equation is of the form

$$w_{0,0} = 0,$$

$$\Delta_h w_{ij} = f_{ij}, \qquad (x_i, y_j) \in D - \{(0, 0)\},$$

$$l_h w_{ij} = \sum_r \mu_{ijr}\alpha(s_r) + h\left[\sum_r \zeta_{ijr} \frac{\partial\alpha}{\partial s}(s_r) + \nu_{ij} f_{ij}\right],$$

$$(x_i, y_j) \in D_0,$$

where Δ_h is the usual five-point difference analogue and l_h has the form

$$l_h w_{ij} = h^{-1}\left[\sum_{(i-\xi)^2+(j-\eta)^2 \neq 0} \lambda_{ij\xi\eta} w_{\xi\eta} - w_{ij}\right].$$

The parameters satisfy the relations

$$\lambda_{ij\xi\eta} \geq 0, \quad \lambda_{ij\xi\eta} = 0 \quad \text{if } (i-\xi)^2 + (j-\eta)^2 \geq C_0^2,$$

$$\sum_{(\xi,\eta)\in D\cup D_0} \lambda_{ij\xi\eta} = 1, \qquad \sum_{(\xi,\eta)\in D} \lambda_{ij\xi\eta} \geq C_1, \qquad C_1 > 0,$$

and can be chosen so that

$$l_h\varphi_{ij} = \sum_r \mu_{ijr} \frac{\partial\varphi}{\partial\rho}(s_r) + h\left[\sum_r \zeta_{ijr} \frac{\partial^2\varphi}{\partial\rho\,\partial s}(s_r) + \nu_{ij}\Delta\varphi(x_i, y_j)\right] + h^2\vartheta_{ij}\varphi_{ij}^{(3)},$$

where

$$\mu_{ijr} \geq 0, \quad \sum_r \mu_{ijr} \geq C_2, \quad \sum_r |\zeta_{ijr}| + |\nu_{ij}| < C_3, \quad |\vartheta_{ij}| < C_4,$$

and $\varphi_{ij}^{(3)}$ bounds all third derivatives of φ in the neighborhood of (x_i, y_j). The boundary condition is called starlike with respect to a point $p \in G$ if $\cos(\rho, R) \leq -C_5$, where R is the radius vector from p, on all of ∂G. He proves that $|\varphi - w| = O(h^{2-2/|\log h|}(\log h)^2)$ for starlike regions under the smoothness conditions mentioned above. He then shows that the same estimate holds if the requirement that G be starlike is replaced by the requirement that $\cos(n, \rho) \leq C_6 < 1$, where n is the interior normal, be valid on ∂G. He follows these results with a number of remarks on weaker hypotheses and higher dimensions.

Nikolaev, P. V. 4222

On the representation of equations by nomograms of the second kind. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1293–1296.

The author indicates that the conditions for a function $t_3 = f(t_1, t_2)$ to be represented by a nomogram in which the scale t_3 is on a straight line, notwithstanding the great number of papers published on this subject, have never been stated. {T.-H. Gronwall [J. Math. Pures Appl. (6) 8 (1912), 59–102] considered the general conditions and analysed the nomograms with three and two scales along a straight line, as well as those with two scales on the same conic. He showed that for nomograms in which two scales are on straight lines the representation problem can be solved without quadratures.} The author proves, starting with the equation of Massau, that the conditions given by him in his paper are necessary and sufficient for a function to be represented by the required nomogram. He solves the representation problem by quadratures, the general formulas being explicitly given, and shows that, but for a collineation, the representation is unique.

A machine method of designing junctions. (Russian)

Vyčisl. Sistemy No. 6 (1963), 32–40.

The author prescribes machine methods for joining pairs of distinct cells of a lattice diagram by a minimum path if (a) certain preassigned cells of the diagram are not to

contain segments of the path, and (b) the number of intersections with a preassigned path is the least possible.
E. J. Cogan (Bronxville, N.Y.)

Hillsley, R. H.; Robbins, H. M. 4225

A steepest-ascent trajectory optimization method which reduces memory requirements.
Computing Methods in Optimization Problems (*Proc. Conf., Univ. California, Los Angeles, Calif.*, 1964), *pp.* 107–133. *Academic Press, New York*, 1964.

From the authors' introduction: "This paper describes an iterative process for steepest-ascent optimization of orbit transfer trajectories. The method is designed to minimize storage requirements, at the expense of a small amount of additional computation. The reduced memory requirements eliminate the need for tape operations on the IBM 7090 when the method is used to compute nominal trajectories. In-flight use, by a guidance computer of limited memory, appears feasible."

Hrapčenko, V. M. 4226

An error bound for binary multiplication. (Russian)
Problemy Kibernet. No. 10 (1963), 165–177.

In the multiplication of two n-place numbers in a machine with a register of length $2n$, roundoff can be accomplished after the multiplication, and the error is easily calculated. Under some conditions, however, it is preferable to round at the end of each product of the multiplicand by a digit of the multiplier. This paper is a study of the error resulting from the second process.

Let $A=\sum_{i=1}^n a_i 2^{-i}$ be the multiplier and $B=\sum_{j=1}^n b_j 2^{-j}$ the multiplicand, with each a_i, b_j equal to 0 or 1. Consider roundoff, by the usual rule, of the product $Ba_i 2^{-i}$ for each i, $1\leqq i\leqq n$, to $n+p$ bits, where $p<n$. The total error in the product is $2^{-(n+p)}\delta$, where

$$\delta = 2^{-1}\sum_{i=p+1}^{n} a_i b_{n+p-i+1} - \sum_{i=p+2}^{n}\sum_{k=2}^{i-p} a_i b_{n+p-i+k} 2^{-k}$$

and $k=i+j-n-p$. It is proved that δ attains its greatest value when $a_{p+1}=a_n=1$, the sequence $a_{p+2}\cdots a_{n-1}$ is either $101010\cdots$ or $010101\cdots$, and the bits $b_{p+1},\cdots,b_n$ are related to the a's by the equation $a_i=b_{n+p-i+1}$, $p+1\leqq i\leqq n$. This largest value is $[3(n-p)+7-2^{p-n+1}]/18$. Analogous results are obtained for min δ. The inequality $n-p+2<3\cdot 2^p$ is derived for the determination of p when the error is given in advance. A comparison is made between the smallest value of p obtained for a given error under true roundoff of each product $Ba_i 2^{-i}$ (as above) and under truncation of this product at the $(n+p)$th place.

Gilbert, Elmer G. 4227

The application of hybrid computers to the iterative solution of optimal control problems.
Computing Methods in Optimization Problems (*Proc. Conf., Univ. California, Los Angeles, Calif.*, 1964), *pp.* 261–284. *Academic Press, New York*, 1964.

From the author's introduction: "This paper explores certain programming aspects of hybrid computation as they pertain to the iterative solution of time optimal control problems. After reviewing the iterative procedures due to Eaton [J. Math. Anal. Appl. 5 (1962), 329–344; MR 25 #4214] and Neustadt [ibid. 1 (1960), 484–493; MR 23 #B1612; 'On synthesizing time optimal control systems', Second Congr. Internat. Federation of Automatic Control (Basel, 1963)], related procedures are derived which are better suited to hybrid computation. Then the programming of these procedures is described, along with a brief discussion of the characteristics of hybrid computers. Finally, some computer results are presented."

★The variational principles of mechanics.
Second edition. Mathematical Expositions, No. 4.
University of Toronto Press, Toronto, Ont., 1962 (*reprinted* 1964). xxv + 367 *pp.* $7.50.

This is an excellent book which covers a great deal of information on variational methods. The brilliant accomplishments as explained in the text would definitely be welcomed by students and teachers of analytical mechanics.

This book is a corrected edition of the previous (1949) edition [MR 11, 549] with the excellent addition of a chapter on relativity. The author traces the historical development, beginning from the basic ideas of mechanics to the more powerful and advanced methods of D'Alembert, Lagrange, Hamilton, canonical transformations and the Hamilton-Jacobi equation. A number of clear specific examples are presented and terse, clear summaries are given in each section. The fundamental results explained in each section enable the readers to follow the trend and general line of thought in a most clear and lucid fashion. A good illustration is Chapter V (50 pages) entitled, "The Lagrangian Equations of Motion". Using the principles in the previous chapter entitled "D'Alembert Principle", the reader is introduced to the "Hamilton's Principle". This method is the most

direct and most natural transformation of D'Alembert into a minimum principle or, more generally, the stationary value of a definite integral. The step-by-step procedure leads from the Hamilton principle to the Lagrange equation, Jacobi's principle and Lagrangian multiplier. The holonomic and scleronomic systems, i.e., the Lagrangian L which does not contain the time explicitly, are explained very clearly. The final portion of this chapter concludes with the application of the principles to the theory of small vibrations. The last chapter (IX) is an excellent introduction to relativistic mechanics. Based upon the previous Hamiltonian formulation, additional information on Einstein's observations plus Minkowski's classic paper on the four-dimensional world and Lorentz transformations, the basic elementary concept of "General Relativity" is explained in a very simple fashion.

The reviewer regrets that the author has not expanded his work to encompass the variational principles of solid mechanics. The application of Rayleigh-Ritz, Galerkin and Reissner's method would be a most welcome addition to this book. With the advent of digital computers, these variational applications to solid mechanics play a most important part. *H. Saunders* (Philadelphia, Pa.)

Dupont, Pascal 4231

Sulla determinazione della curvatura delle polari nei moti rigidi piani.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 397–417.

The author indicates that geometrical and analytical methods are equally valuable in the study of the kinematics of rigid moving planes, his interest here being in the points of contact of the polars and their radii of curvature, two pairs of conjugate profiles being given. The analytical treatment by Grübler in his articles on the motion of the poles [Z. Math. Phys. **29** (1884), 212–221; ibid. **34** (1889), 305–310] is criticised for lack of generality. Certain particular cases of moving profiles are considered, notably the beam of an articulated quadrilateral.

G. Huxley (Belfast)

Dupont, Pascal 4232

Il teorema di Bobillier, il problema della retta tangente alle polari e sua applicazione per la determinazione del centro delle accelerazioni.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 442–471.

The contents are adequately indicated by the title. Two theorems of Bobillier (1797–1832) are considered, together with their kinematical interpretation by Aronhold. Burmester's treatment of Bobillier's construction [Burmester, *Lehrbuch der Kinematik*, Leipzig, 1888] is touched upon, and a trigonometrical demonstration of his theorems provided. The critical survey ends with an application of Bobillier's ideas to the study of centres of acceleration.

G. Huxley (Belfast)

Dupont, Pascal 4233

Determinazione grafica del centro di curvatura della polare fissa nei moti rigidi piani.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 489–513.

The author considers the problem of determining the centre of curvature of the fixed polar, given the position of a moving plane by means of two pairs of conjugate profiles. L. Burmester's graphical solution [*Lehrbuch der Kinematik*, p. 106, Leipzig, 1888] is examined and corrected, and then another graphical solution is offered, involving quite complicated constructions. The tendency is less historical than in the other papers in this series.

G. Huxley (Belfast)

Arens, Richard 4234

Differential-geometric elements of analytic dynamics.

J. Math. Anal. Appl. **9** (1964), 165–202.

The author describes at some length an approach to classical mechanics via the theory of Pfaffian forms. This approach is based to a large extent on his point of view according to which "the Hamilton-Jacobi technique ... is just a procedure for reducing Pfaffians (that is, covariant vector fields) to normal form". The first section of the paper is devoted to this topic (largely in the form of examples). This is followed by some remarks concerning the connection between the calculus of variations and the theory of Pfaffians. The usual phase space is described at some length in terms of the tangent bundle of the underlying configuration space. This leads to a discussion of extremals of variational problems, including geodesics of Riemannian geometry. The so-called absolute mechanical systems are then defined in such a way as to facilitate a direct application of the method of Pfaffians, which in turn gives rise to a comparison of classical with relativistic mechanics. *H. Rund* (Pretoria)

Pollard, Harry 4235

A sharp form of the Virial Theorem.

Bull. Amer. Math. Soc. **70** (1964), 703–705.

Soit un système S de n points matériels, soumis à l'attraction newtonienne, le centre de masses étant fixe, T son énergie cinétique totale, h la constante d'énergie ($T+V=h$). l'auteur prouve que l'égalité

$$\lim_{t\to\infty} \frac{1}{t}\int_0^t T(\tau)\,d\tau = -h$$

est vraie si et seulement si, $R(t)$ désignant le maximum des distances mutuelles des points, on a l'égalité $R(t)=o(t)$ pour $t\to\infty$. La partie délicate de la démonstration utilise un certain théorème de Landau, pour lequel on pourra se reporter à un article de Boas [Duke Math. J. **3** (1937), 637–646].

Sans aucune hypothèse a priori sur la croissance du système S, l'auteur prouve d'autre part le théorème suivant: $\limsup_{t\to\infty} (1/t)\int_0^t T(\tau)\,d\tau \ge |h|$.

Five precision point synthesis of the four-bar function generator.

Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 563–564.

Author's introduction: "Presently used algebraic methods for synthesizing the four-bar function generator usually yield compatibility equations having extraneous roots. Use of a superposition technique for the case of five precision points leads to a cubic compatibility equation

free of extraneous roots. The method presented here lends itself well to programming for a digital computer, available library subroutines sufficing for the more critical and tedious portions of the computation."

Raitzin, Carlos 4237

On the variational principles of dynamics. (Spanish)

An. Soc. Ci. Argentina **176** (1963), 62–70.

In a previous paper [same An. **171** (1961), 50–65; MR **23** #B1711] the author has introduced a new function $R(s_i, r_i) = L - \sum q_i r_i$ with L: Lagrange's function, $s_i = \dot{q}_i$, $r_i = \dot{p}_i$. In this paper, the author develops four variational properties, using Hölder's operator $\Delta = (\partial/\partial\varepsilon + (d/dt) \times (dt/d\varepsilon))\delta\varepsilon$ (which amounts to considering non-synchronous variations). (1) $\Delta \int_{t_1}^{t_2} R\,dt = 0$; (2) $\Delta(A_c + A_p) = 0$, which is a generalization of Maupertuis' principle, A_c being the kinetic action $\int_{t_1}^{t_2} \sum p_i s_i\,dt = \int_{t_1}^{t_2} \sum (\partial L/\partial \dot{q}_i)\dot{q}_i\,dt$ and A_p being the newly defined potential action $\int_{t_1}^{t_2} \sum r_i q_i\,dt = \int_{t_1}^{t_2} \sum (\partial L/\partial q_i) q_i\,dt$ (this result is valid for non-conservative systems having a Lagrangian); (3) $\delta \int_{t_1}^{t_2} (R - H)\,dt = 0$, which is an extension of Hamilton's principle; (4) Proof of Hamilton's principle $\delta \int_{t_1}^{t_2} L\,dt = 0$ for non-synchronous paths, i.e., $\delta t \neq 0$. *J. Kestens* (Brussels)

Sul divario fra due campi cinetici.

Ist. Lombardo Accad. Sci. Lett. Rend. A **97** (1963), 274–281.

Résumé de l'auteur: "Calcolato il divario fra due campi cinetici dati, lo si interpreta come distribuzione delle velocità 'relative' ad uno di essi. Si stabilisce, di conseguenza, una estensione sia del teorema di Coriolis, sia delle formule di Poisson."

J. Charles-Renaudie (Montpellier)

Udeschini Brinis, Elisa 4239

Sui sistemi meccanici dinamicamente equivalenti.

Ist. Lombardo Accad. Sci. Lett. Rend. A **97** (1963), 592–602.

The dynamical systems under consideration are holonomic with constraints which are independent of the time. The configuration space of a system having kinetic energy T is regarded as a Riemannian space with the metric $ds^2 = 2T\,dt^2$. Two systems, m and μ, each with n degrees of freedom, are said to be dynamically equivalent if coordinates $q^1, q^2, \cdots, q^n$ for m, and coordinates $\chi^1, \chi^2, \cdots, \chi^n$ for μ, can be chosen so that q^i and χ^i are identically equal, as functions of t, for all values of the index i. It is shown that a necessary and sufficient condition that two systems, m and μ, with kinetic energies T and $\mathcal{T}$, respectively, be dynamically equivalent is that $D^i{}_{hk}\dot{q}^h\dot{q}^k = \Phi^i - F^i$ ($i = 1, 2, \cdots, n$). Here F^i and Φ^i are components of the (contravariant) generalized forces applied to m and μ, and $D^i{}_{hk} = \left\{\begin{Bmatrix} i \\ h\ k \end{Bmatrix}\right\} - \begin{Bmatrix} i \\ h\ k \end{Bmatrix}$, the terms in the right-hand member being the Christoffel symbols of the second kind calculated with respect to the metrics $d\sigma^2 = 2\mathcal{T}\,dt^2$ and $ds^2 = 2T\,dt^2$, respectively. (It is understood that the calculation of $D^i{}_{hk}$ and Φ^i involves setting $\chi^i = q^i$ for $i = 1, 2, \cdots, n$.) The paper concludes with an extended discussion of the case in which m is subjected to a conservative force derived from a potential U, and in which the metrics of the configuration spaces of m and μ satisfy the relation $d\sigma^2 = 2(E + U)E^{-1}\,ds^2$, the constant E being the total energy of the system m. In this case, if the two systems are dynamically equivalent, the dynamical trajectories of μ in its configuration space are geodesics. The case includes several subcases presenting various features of interest. *L. A. MacColl* (New York)

Datzeff, Assène [Dacev, A.] 4240

Sur les principes d'extremum en mécanique classique.

C. R. Acad. Sci. Paris **259** (1964), 56–59.

In applying Hamilton's principle to a conservative holonomic system, one considers a natural motion from one configuration to another and a family of generally unnatural neighboring motions joining the same two configurations. In the present note the author considers each of the varied motions as a natural motion under appropriately defined forces, and he discusses relations between the values of the action integral calculated for the original natural motion and for the several varied motions. The purpose of these unusual considerations is not clearly explained. *L. A. MacColl* (New York)

Sui sistemi anolonomi riducibili a forme lagrangiane.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 375–382.

A discussion of some situations in which a nonholonomic dynamical system is equivalent to a holonomic system admitting certain integrals, linear or quadratic in the velocities. The details of the argument are not entirely clear to the reviewer. *L. A. MacColl* (New York)

Vujicić, Veljko [Vujičić, V. A.] 4242

Sur certaines questions de la mécanique analytique des systèmes non holonomes.

C. R. Acad. Sci. Paris **259** (1964), 709–711.

From the author's summary: "Nous avons mis en évidence la possibilité de former toutes les équations de la dynamique, ainsi que celles, plus générales, de la physique à partir d'un principe général de la mécanique, connu comme méthode de Pfaff ou de Pfaff-Bilimović. Dans ce travail nous montrerons comment cette méthode peut être utilement appliquée à l'étude des systèmes non holonomes grâce à l'emploi des quasi-coordonnées."

Czarnecki, Adam Z. 4243

Physical systems S_k of curves in a central field of force.

Math. Notae **19** (1964), 137–146.

Ein Massenpunkt (Ortsvektor $\mathbf{r}(x, y, z)$, Masse $m = 1$) sei durch das Kraftfeld $\mathbf{F}(x, y, z)$ gezwungen, eine Kurve C (Ortsvektor $\mathbf{r}(t)$) zu durchlaufen. Es seien s die Bogenlänge und ρ der Krümmungsradius der Bahn C, ferner v die Geschwindigkeit des Teilchens, schließlich $r' = dr/ds$ usw. Ein physikalisches System S_k besteht dann nach E. Kasner und J. DeCicco [Proc. Nat. Acad. Sci. U.S.A. **35** (1949), 106–108; MR **10**, 398] aus allen Kurven C, längs denen eine Zwangsbewegung mit der Eigenschaft möglich ist, daß die Schmiegebene in jedem Punkt der Kurve C den dort wirkenden Kraftvektor $\mathbf{F}$ enthält und der Druck P,

definiert durch $P = mv^2/\rho - F_N$ mit einem Faktor k proportional ist zu der Normalkomponente $F_N = \rho(\mathbf{F}\cdot\mathbf{r}'')$ von $\mathbf{F}$. Längs jeder Kurve C eines physikalischen Systems S_k gilt also $P = kF_N$. Besondere Fälle ergeben sich für $k = 0$ (Kraftlinien S_0), $k = 1$ (allgemeine Kettenlinien S_1), $k = -2$ (allgemeine Brachystochronen S_{-2}), $k \to \infty$ (Geschwindigkeitssystem S_∞; die Bahnkurven der Massenpunkte, die mit fester Geschwindigkeit in Kraftrichtung starten, haben dabei Bahnen, welche die Kraftlinien oskulieren). Der Fall $k = -1$ ist auszuschließen.

Die Arbeit studiert hauptsächlich den Fall eines zentralen Kraftfeldes. Die Kraftvektoren sind dann dem Ortsvektor proportional: $\mathbf{F} = \phi(x, y, z)\mathbf{r}$, wobei im konservativen Fall $\phi = \phi(r)$ ist. Die ∞^6 Kurven C von S_k sondern sich dann in ∞^2 Familien von ebenen Kurven. Auch die Umkehrung gilt ($k = 0$ gibt den Satz von Halphen). Verallgemeinerungen des Keplerschen Flächensatzes ($k = 0$) auf den Fall $k \neq 0$ ergeben sich als Folgerungen aus der Differentialgleichung des physikalischen Systems S_k.

Schließlich wird noch der Fall eines konservativen Zentralkraftfeldes studiert. Das physikalische System S_k ($k \neq -1$) oder S_∞ in Polarkoordinaten zu beschreiben erfordert dann lediglich zwei Integrationen, wobei die erste das Energieintegral liefert. Kennt man die Potentialfunktion des Zentralfeldes, so reicht eine Integration aus.

Das Problem, physikalische Systeme S_k im einfachen Fall eines Newtonschen Zentralfeldes zu finden, ist damit auf zwei Quadraturen zurückgeführt, die aber nur in bestimmten Fällen (z.B. für $k = 0$) elementar ausfallen.

K. Strubecker (Karlsruhe)

Transverse vibrations of a string of variable length. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 319–322.

Authors' summary: "With the help of asymptotic methods a solution is obtained for the problem of transverse vibrations of a string of variable length with mobile ends. It was found that in the first approximation the amplitudes of the free tones are constant for a string of variable length, while the total energy of the transverse vibrations vary in inverse proportion to the length of the vibrating string $l_0 - l$. The form of the weak dependence between various tones of the free vibrations of a string of variable length is determined. The solutions obtained may be used for calculating the flexible elements of transporting and hoisting devices."

Quick, William H. 4248

Theory of the vibrating string as an angular motion sensor.

Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 523–534.

Equations are presented for the vibration of a string driven by longitudinal motion at one end. It is assumed that axial frequencies in the string are much higher than lateral frequencies. It is shown that non-linear effects play a predominant influence in the usefulness of this concept as a "gyro". With large amplitude in one direction and smaller amplitude transversely, frequencies are unequal in the two directions, and precession occurs. Other conditions for precession are also presented.

Schmidt, Günter 4252

Zur Stabilität der Längs- und Querschwingungen eines längs pulsierend belasteten Stabes.

Math. Nachr. **27** (1963/64), 341–351.

Unter Verwendung der Floquet'schen Theorie werden die Stabilitätsbedingungen für ein System linearer Differentialgleichungen mit periodischen Koeffizienten in sehr allgemeiner Form angegeben. Diese Ergebnisse werden dann auf das Problem der parametererregten Schwingungen eines gelenkig gelagerten, in der Längsrichtung pulsierend belasteten Stabes angewendet. Für den Fall der Längsschwingungen kommt man auf diese Weise zu expliziten Angaben über die Stabilität. Bei den Querschwingungen müssen die Fälle der einfachen und der Kombinationsresonanz unterschieden werden. Hier werden die Bereiche des Überhängens und die Existenz periodischer Lösungen berechnet. *K. Magnus* (Stuttgart)

On the unstable vibrations of a shaft carrying an unsymmetrical rotor.

Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 515–522.

Authors' summary: "In a rotating shaft system carrying an unsymmetrical rotor, there is always one unstable region in the neighborhood of the rotating speed at which the sum of two natural frequencies of the system is equal to twice the rotating speed of the shaft. In this unstable region two unstable lateral vibrations with frequencies P_1 and P_2 take place simultaneously and grow up steadily. Generally, frequencies P_1 and P_2 are not equal to the rotating speed ω of the shaft and the sum of these P_1+P_2 is always equal to 2ω. Of course there are other unstable regions which appear at the major critical speeds."

Nuove forme per le equazioni in coordinate generali della statica dei continui con caratteristiche di tensione asimmetriche.

Ann. Scuola Norm. Sup. Pisa (3) **17** (1963), 297–317.

The author studies the tensor formulas for various physical quantities associated with two sets of reference frames. The quantities studied are force, velocity,

acceleration, moments, strain components, etc. Formulas for the behavior of these quantities under coordinate change are given, and a detailed examination of the quantities is furnished. The work is an extension of work by C. Truesdell and R. Toupin [*Handbuch der Physik*, Bd. III/1, pp. 226–793, Springer, Berlin, 1960; MR **22** #8778] and other authors [see, for instance, A. Knops, R. J. 4259

Uniqueness for the whole space in classical elasticity.

J. London Math. Soc. **39** (1964), 708–712.

The author is concerned with the equations of classical elasticity in which the Lamé constants λ and μ are permitted to vary outside the range of physical interest. He shows that (i) If the displacement vector tends uniformly to zero at infinity and satisfies the field equations of elasticity in the whole space, then it vanishes identically everywhere provided $\lambda+2\mu\neq 0$, $\mu\neq 0$; (ii) If the stress components tend uniformly to zero at infinity and satisfy the field equations of elasticity in the whole space, then they vanish identically everywhere provided $\lambda+2\mu\neq 0$.

From this and appropriate examples it follows that for solutions of the field equations which satisfy certain order conditions at infinity, the requirement $\lambda+2\mu\neq 0$, $\mu\neq 0$ is both necessary and sufficient for uniqueness in the displacement boundary-value problem. On the other hand, if the stresses vanish appropriately at infinity, a necessary and sufficient condition that the stress be unique is that $\lambda+2\mu\neq 0$.

Resende, Eliseu 4261

Generalized progressing wave expansion for the equations of elasticity.

An. Acad. Brasil. Ci. **36** (1964), 7–11.

Author's introduction: "The purpose of this work may be described as an application of the methods of geometrical optics to initial-boundary value problems in elasticity. A generalized progressing wave expansion is constructed by performing the transition from the partial differential equations of motion in elasticity to ordinary differential equations along bicharacteristics. In the special case of periodic solutions these generalized progressing wave expansions become asymptotic expansions with respect to the frequency [F. C. Karal and J. B. Keller, J. Acoust. Soc. Amer. **31** (1959), 694–705; MR **21** #2416]. By letting the wave form a distribution, these expansions permit the discussion of the propagation of discontinuities [R. Courant and P. Lax, Proc. Nat. Acad. Sci. U.S.A. **42** (1956), 872–876; MR 18, 399] in an elastic medium."

Spencer, A. J. M. 4262

Finite deformations of an almost incompressible elastic solid.

Second-order Effects in Elasticity, Plasticity and Fluid Dynamics (Internat. Sympos., Haifa, 1962), pp. 200–216. Jerusalem Academic Press, Jerusalem; Pergamon, Oxford, 1964.

This paper deals with isotropic elastic materials which, under finite deformation, allow only small relative changes in elemental volume of order ε. These materials are classified as almost incompressible elastic solids. A theory is developed which permits treatment of finite elasticity problems for this class of solids once the solution to the geometrically equivalent but strictly incompressible solid is obtained. The approach is based on expansion of the strain-energy function in powers of (I_3-1), where I_3 denotes the third strain invariant. The resulting equations possess certain similarities to those obtained in the theory of small deformations superposed on large deformations of elastic solids.

An illustration is given in which the author treats the problem of simultaneous extension, inflation and torsion of an almost incompressible circular cylinder.

Mahovikov, V. I. 4263

A dynamic problem of elasticity theory for a plate of transversely isotropic material. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, no. 4 (41), 111–117.

Four boundary conditions are considered in this paper. With the usual notation in thin-plate theory they are, on $z=\pm h$:

(1) $\sigma_z = q\sin\gamma ct,\qquad \tau_{xz}-i\tau_{yz} = \pm p\sin\gamma ct;$

(2) $w = \pm q\sin\gamma ct,\qquad u-iv = p\sin\gamma ct;$

(3) $w = \pm q\sin\gamma ct,\qquad \tau_{xz}-i\tau_{yz} = \pm p\sin\gamma ct;$

(4) $\sigma_z = q\sin\gamma ct,\qquad u-iv = p\sin\gamma ct.$

Ghosh, Basudev 4272

Torsion of a composite beam of rectangular cross-section.

J. Tech. Bengal Engrg. College 7 (1962), 121–130.

The torsion problem for a composite beam of rectangular section is solved by means of the classical method of constructing the Green's function for the two regions involved.

B. R. Seth (Kharagpur)

Golubev, O. B. 4273

A generalization of the theory of thin rods. (Russian)

Leningrad. Politehn. Inst. Trudy No. 226 (1963), 83–92.

The classical theory of the small deformation of thin rods is due to Kirchhoff and Clebsch; a modern account can be found in a paper by Lur'e [same Trudy No. 3 (1941), 148–157]. The theory of equilibrium and stability of thin-walled elastic rods with rectilinear axes was developed by Adadurov, Vlasov, Umanskiĭ and others, while rods with curvilinear axes were investigated by Džanelidze. (Full references to Soviet work are given in the paper under review.) The author considers the small deformation of a thin solid (or a thin-walled) elastic isotropic rod whose axis is a general space curve. Two kinematical assumptions are made: (1) deformations in the plane of a cross-section of the rod are absent, that is, the displacement of a point of the section consists of a displacement of the section as a rigid whole together with warping of the section in the perpendicular direction;

and (2) warping of the section is proportional to a certain known function, here taken to be the Saint-Venant warping function. Expressions, in terms of integrals taken over a general cross-section, are obtained for the potential energy of deformation and for the work done by the external forces applied to the rod. The complete set of equations pertaining to the theory is displayed in the final section of the paper. *J. Hubert Wilkinson* (Battersea)

Herrmann, L. R. 4274

A three-dimensional elasticity solution for continuous beams.

J. Franklin Inst. **278** (1964), 75–83.

Author's summary: "A method for the development of solutions, within the framework of three-dimensional elasticity, for continuous beam problems is illustrated. A three-dimensional continuous beam analysis will find utility in analyzing beam-like structures whose cross-sectional dimensions, as compared to their span lengths, are such that neither the usual beam assumption (which yields a one-dimensional problem) or the plane stress assumption (which yields a two-dimensional problem) can be invoked. Thus, since neither the beam nor plane stress assumptions have been applied, the structural element under consideration may be as deep or wide as desired. Additionally, a beam subjected to a load which varies with the transverse direction may be rigorously analyzed. The solution is restricted to a continuous beam in which the loading conditions are identical over each span. The solution is in the form of two double series, the first of which is a double Fourier series, the second a combination Fourier and Fadle eigenfunction series."

Makai, E. 4277

On the principal frequency of a membrane and the torsional rigidity of a beam.

Studies in mathematical analysis and related topics, pp. 227–231. *Stanford Univ. Press, Stanford, Calif.*, 1962.

For a beam with a cross-section given by any simply connected plane convex domain D, the author finds two upper bounds for the torsional rigidity

$$P \leq \frac{8}{3}\frac{A^3}{L^2}, \qquad P < \frac{4}{3}A\rho^2,$$

where A is the area of D, L is the length of the perimeter of D, and ρ is the radius of the greatest circle contained in D.

For a membrane over any simply connected plane convex domain D, the author finds a lower bound for the principal frequency

$$\Lambda \geq \frac{\pi}{4}\frac{L}{A},$$

where L and A are defined as above.

A. Phillips (New Haven, Conn.)

Tola, José [Tola Pasquel, José] 4278

Application of Kani's method to structures with variable cross-section. (Spanish)

Univ. Nac. Ingen. Inst. Mat. Puras Apl. Notas Mat. **2** (1964), 8–15.

This paper deals with the problem of building frames made out of beams of variable cross-sections. The author refers to equations established by him previously in 1954. As it is classical, three states of the structure are considered. (1) The "initial" state where the structure is deformed by the given vertical loads and such that the joints do not move or rotate; this is possible by introducing horizontal forces and end moments to the beams. (2) The "complementary" state where the structure is subjected to these forces and moments, with reversed signs. (3) The "actual" state which results as the superposition of (1) and (2).

State (1) can be solved using tables established by Kani (1958); the coefficients which are to be computed are those appearing in H. Cross's method. The author shows how to solve state (2). A numerical example would have permitted one to follow the different steps of the computation. *J. Kestens* (Brussels)

The torsional rigidity of tubes of constant normal thickness.

Proc. Cambridge Philos. Soc. **60** (1964), 1023–1026.

An inequality given by J. L. Synge is used as the basis of a method of approximating the torsional rigidity of a thin tube. *J. W. Craggs* (Melbourne)

Zargarjan, S. S. 4280

Torsion of a circular cylinder having a non-coaxial polyhedral cavity. (Russian. Armenian summary)

Akad. Nauk Armjan. SSR Dokl. **38** (1964), 217–224.

The author considers a bar with doubly connected constant cross-section. The inner boundary is a square with rounded-off corners and the external boundary is a circle. The center of the circle does not coincide with that of the square. A conformal transformation is used with the aid of the generalized Laurent power series. For the

example given in the paper the transformation $z = D(1/w - w^3/b)$, $w = (\zeta_1 - \alpha)/(1 - \bar{\alpha}\zeta_1)$, $\zeta_1 = re^{i\varphi}$ is employed. The torsion rigidity and the stresses are obtained.

Izdebs'ka, G. A.; Kil'čevs'kiĭ, M. O. 4282

On the convergence of the collocation method and the optimal choice of the collocation points in connection with the integro-differential equations of equilibrium in the theory of plates. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 469–472.

Authors' summary: "The authors consider the development of the method of collocation as applied to integro-differential equations of equilibrium of rectangular plates of variable thickness. An integro-differential equation is deduced, defining the error of the initial approximation, and the process of obtaining successive approximations is indicated. The general principles of the optimal choice of collocation points are outlined."

Morley, L. S. D. 4283

Bending of clamped rectilinear plates.

Quart. J. Mech. Appl. Math. **17** (1964), 293–317.

In a recent paper, the author showed [same J. **16** (1963), 451–471; MR **28** #2691] that the small deflection bending of a clamped plate can be simplified by the reduction to the variational solution of two successive membrane boundary-value problems. In the present paper he uses this reduction to derive a solution which is strictly valid when the boundary is finite, simply connected and smooth—and which is also satisfactory in the engineering sense for many problems where the boundary is rectilinear. Particular attention is given to the irregular behaviour which generally occurs in the corners. A numerical example is treated, and data are given for the clamped rhombus plate under a uniformly distributed load and under a central concentrated load.

H. D. Conway (Ithaca, N.Y.)

Landau, H. G. 4284

The elastic-plastic plate under cycles of moving dilatations and small applied load.

J. Mech. Phys. Solids **11** (1963), 97–117.

Author's summary: "An elastic and perfectly plastic plate is subjected to cycles of phase transformations which produce alternately positive and negative dilatations. The dilatations move symmetrically from the faces to the centre of the plate and vary only in the direction perpendicular to the faces. Simultaneously a constant load, which is small relative to the yield stress, is applied in a direction parallel to the faces of the plate.

"Equations based on the Tresca yield and flow condition are given for the stress and strain rates at any time, in terms of the existing stress distribution and the rate of change of the dilatation. Conditions for plastic flow to occur are derived, and it is shown that shakedown does not take place. For the special case of dilatation occurring in a zone of zero width, the stress-rate equations are integrated analytically for the first half-cycle of dilatation and for repeated cycles without the applied load. For the general case numerical integration is used. It is found that a periodic stress distribution is established after a few cycles, with strains which change at a constant rate per cycle and are proportional to the applied load."

A. Phillips (New Haven, Conn.)

Guo, Zhong-heng 4285

Certain problems of initially deformed plates. (Polish and Russian summaries)

Arch. Mech. Stos. **14** (1962), 779–788.

The equations of motion are written for rectangular, square, triangular and elliptical plates, assuming homogeneous finite deformations with additional small deformations. Proceeding from certain boundary conditions, the author gives formal solutions for the material frequencies and buckling conditions.

M. Mişicu (Bucharest)

Abubakar, Iya 4286

Free vibrations of a transversely isotropic plate.

Quart. J. Mech. Appl. Math. **15** (1962), 129–136.

Author's summary: "In this paper the boundary value problem concerning the propagation of plane harmonic waves in a thin, flat, homogeneous, transversely isotropic plate of finite width and infinite length in vacuum is solved. The frequency equations corresponding to the symmetric and antisymmetric modes of vibration of the plate are obtained, and some limiting cases of the frequency equations are then discussed. Finally, numerical solution of the frequency equations for a beryl plate is carried out, and the dispersion curves for the first two modes of the symmetric and antisymmetric vibrations are presented."

Prasad, B. 4287

Fracture of thick flat plates of elastic-plastic material under uniform stress.

J. Math. Anal. Appl. **9** (1964), 119–137.

A thick rectangular plate is loaded in uniform inplane unaxial tension under plane strain conditions. It is assumed that at a critical load τ the plate will be divided into elastic and plastic regions by a plane Σ which is perpendicular to the plane of the plate and whose normal makes an angle θ with the tensile direction. It is further assumed that Hooke's law applies in the elastic region and Hencky's law in the plastic region. A static analysis is made first. If the material is incompressible, it is shown that θ must be 45° to satisfy these assumptions. For a compressible material θ is determined from the further assumption that the plastic energy density function is an extremum to be either 0° or given by $\theta = \cos^{-1}[2(1-\nu+\nu^2)/3]^{1/2}$, which is slightly less than 45°. It is suggested that $\theta = 0°$ corresponds to cleavage fracture and θ near 45° to shear failure.

It is further shown that for the compressible material

there is discontinuity of the stress tensor across Σ according to the static analysis. Therefore dynamic conditions are introduced, and it is shown that for $\theta=45°$ a discontinuity in tangential velocity remains constant, for θ near 45° it increases continuously, and for $\theta=0°$ it increases infinitely, thus bearing out the suggested modes of failure.

{The reviewer notes that the predicted discontinuity of the stress tensor across Σ implies a rapid change in time of the orientation of the principal directions (since for the load infinitesimally less than τ, the elastic solution applies everywhere) and that under these conditions the Hencky theory of plastic flow is not generally a good approximation to the more realistic Prandtl-Reuss theory. Also, he questions the extremization of the plastic energy density rather than the total plastic energy which would be proportional $1/\cos\theta$ times the density and would presumably predict different values of θ.}

Prokopov, V. K. 4288

The flexure of a heavy circular plate. (Russian)

Leningrad. Politehn. Inst. Trudy No. 226 (1963), 103–108.

The solution of the Navier equations is given for an axially symmetric problem of a thick circular plate such that both the radial displacement and the transverse shear stress vanish along the cylinder boundary. The plate is subjected to its own weight and supported either over a circular area or by a ring of forces. The solution is sought in the form of a product of a zero-order Bessel function defining the variation of the field quantities in the radial direction and an appropriate biharmonic function of the transverse variable. The resulting series is tabulated.

Wilson, P. E.; Boresi, A. P. 4289

Large deflection of a clamped circular plate including effects of transverse shear.

Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 540–541.

Authors' introduction: "A survey of literature on the analysis of flat plates reveals that considerable progress has been made in the formulation of plate theories that include both transverse shear and large deflection terms. However, numerical results for specific problems are still quite limited. In this note the influence of transverse shear on the large axisymmetric deflection of a clamped circular plate subjected to lateral loading is investigated. Numerical results indicate that there exist geometries for which effects of both transverse shear and large deflection are of interest."

Influence of initial stress on the vibrations of simply supported circular cylindrical shells.

AIAA J. **2** (1964), 1607–1612.

The author investigates the influence of uniform circumferential and axial stress on the vibration frequency of thin cylindrical shells with hinged edges, using a more complete theory than previously applied to this problem. He finds previous results obtained by Reissner using shallow shell theory to be accurate except for modes involving a small number of circumferential waves with rather long axial wavelength. His theory permits him to distinguish between circumferential stress produced by hydrostatic and strictly radial pressure, the former resulting in up to 12 percent higher frequencies than the latter.

Allowance for the local nature of the boundary effect in the asymptotic solution of an axi-symmetric problem for shells of revolution. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 476–479.

Author's summary: "It is shown that the main influence of the boundary effect in the general solution of the axisymmetrical problem of shells of rotation is confined to small values $(\Theta-\Theta_H)$ of the order $(h/R)^{1/2}$ (where Θ_H is the value of the argument at the shell edge). Allowing for this fact permits one to eliminate the contradictions present in the estimate of the error of the asymptotic solution of the homogeneous problem and to write this solution in simplified form."

Reissner, Eric 4297

On the form of variationally derived shell equations.

Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 233–238.

Equations for the linear theory of thin elastic shells are derived using a new three-dimensional variational theorem which admits a non-symmetry in the stress tensor and yields the symmetry condition as an Euler equation. This generalization permits assumption of convenient forms for the variation of stress components across the shell thickness. The resulting constitutive equations are simplified to those given by Koiter [Proc. Sympos. Thin Elastic Shells (Delft, 1959), pp. 12–33, North-Holland, Amsterdam 1960; MR **25** #5634] and Sanders [NASA Tech. Rep. R-24 (1959)]. An application to torsion of a circumferentially nonhomogeneous circular cylindrical shell illustrates the importance in some problems of certain terms which are often negligible and are not present in more approximate shell equations.

Reissner, Eric 4298

On asymptotic expansions for circular cylindrical shells.

Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 245–252.

Author's summary: "The paper presents an asymptotic expansion procedure (with reference to decreasing values of wall-thickness shell-radius ratio) for the solutions of the linear theory of the three simultaneous equations for displacements in isotropic circular cylindrical shells. The resultant expansions are applied to a number of fundamental boundary-value problems for a semi-infinite shell. The analysis shows the importance of the joint consideration of differential equations and boundary conditions for a clarification of the asymptotic nature of the solution to be determined." *R. P. Nordgren* (Houston, Tex.)

Karp, Samuel N.; Karal, Frank C., Jr. 4299

The elastic-field behavior in the neighborhood of a crack of arbitrary angle.

Comm. Pure Appl. Math. **15** (1962), 413–421.

A homogeneous elastic medium is considered in which a wedge-shaped section of angle 2α has been removed. A stress-free surface of the remaining medium is taken as boundary condition. The authors examine the types of static deformation which are possible if one imposes the condition that the strain energy density of the elastic field be integrable over any finite region, in particular, one which includes the edge of the wedge. It is assumed that the leading terms of an expansion of the displacement components in powers of r (distance from the edge) are proportional to r^ν. Then it turns out that, due to the boundary condition, the only permissible values are the roots of the equation $(1/2\beta)\sin 2\beta = \pm(1/2\nu\beta)\sin 2\nu\beta$, where $\beta=\pi-\alpha$. The energy condition excludes all roots ν with real part equal to or less than zero. Then the displacements are finite, although the stress becomes infinite at the edge for $0<\operatorname{Re}\nu<1$. It is conjectured that the energy condition can be replaced by the condition of finite displacements. An interesting feature is that the number of real roots ν is always finite, but there are, in addition, always infinitely many complex roots. The results are also significant for the dynamic case and for an elastic medium which has only locally a practically wedge-shaped portion.

Mura, T. 4301

Periodic distributions of dislocations.

Proc. Roy. Soc. Ser. A **280** (1964), 528–544.

The elastic displacement and stress fields are obtained in an anisotropic crystal through which is passing a prescribed sinusoidal plane wave of plastic deformation. The plastic wave is then represented by the corresponding dislocation motion tensor. The results are specialised to periodic fields of stationary dislocations and applied to the example of a hexagonal dislocation network. It is then shown that the equilibrium of any array of dislocation under constant external stress is stable. {The reviewer notes that this result is not true for finite dislocations, as follows from the example of two edge dislocations of opposite sign held in unstable equilibrium on the same glide plane by an external shear stress.} The possible equilibrium states of a periodic distribution are determined, and Fourier analysis is used to determine non-periodic distributions.

On the vibration of a rectangular plate carrying a concentrated mass.

Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 550–551.

Author's introduction: "A new formulation in a series form is given to the problem of vibration of simply supported rectangular plates carrying a concentrated mass in which the Dirac δ-function and finite Fourier sine transforms are used. The infinite set of eigenvalues is

obtained as the roots of a double infinite series, and the 'natural frequencies' of a simply supported rectangular plate occur as a special case of this analysis."

Bolotin, V. V. 4303

Vibration of layered elastic plates. (Polish and Russian summaries)

Proc. Vibration Problems **4** (1963), 331–346.

The author presents the theory of vibration of elastic plates composed of alternate "rigid" and "soft" layers. The theory can be considered as a generalization of the bending of sandwich plates with a soft filler. The plate is considered to be of n equal layers (rigid) and $n-1$ equal layers "soft", each "rigid" layer obeys the Kirchhoff-Love law and in each "soft" layer the stresses σ_x, σ_y and τ_{xy} are negligibly small. The other shear stresses τ_{xz} and τ_{yz} are constant across each "soft" layer and are proportional to the shear distortions γ_{xz} and γ_{yz}. The tangential components of the inertia force are neglected. The author derives the kinetic and potential energy of the plate and load. By application of the Ostrogradsky-Euler equations, the simultaneous partial differential equations for the plate are derived. After further simplifying assumptions and considering the boundary conditions for the simply supported plate, the frequencies for the composite plate are derived. The author extends the method to that of an equivalent anisotropic one-layer plate.

{The reviewer believes that this is an excellent contribution to multilayer plate theory. Present-day designs incorporate a bond between two hard layers and the frequencies can be calculated using this procedure. However, the theory could have been made more general by considering layers of unequal thickness which would be more useful for design purposes. The application to other support conditions can be easily accomplished by employing deflection equations satisfying the boundary conditions.} *H. Saunders* (Philadelphia, Pa.)

Kaczkowski, Zbigniew 4304

Vibration of a beam under a moving load. (Polish and Russian summaries)

Proc. Vibration Problems **4** (1963), 357–373.

L'autore espone un suo metodo di trattazione del problema delle vibrazioni di una trave sollecitata da un carico mobile, argomento questo fondamentale per la teoria dei ponti.

Scritta l'equazione del problema che, con evidente significato dei simboli, è:

$$EJ\frac{\partial^4 y}{\partial x^4}+\mu\frac{\partial^2 y}{\partial t^2} = P\delta(x-vt)$$

la trasforma (con l'introduzione di coordinate adimensionali e facendo opportune posizioni) in una equazione della forma:

$$\frac{\partial^4 y}{\partial \xi^4}+\sigma^2\frac{\partial^2 y}{\partial \tau^2} = \frac{Pl^3}{EJ}\delta(\xi-\tau).$$

L'introduzione di nuove variabili consente l'ulteriore trasformazione in una equazione differenziale alle derivate parziali del quarto ordine simmetrica nelle nuove variabili e di questa ricerca la soluzione nella forma:

$$y(\xi,\tau) = y_1(\zeta)+y_2(-\eta).$$

Per quanto riguarda le condizioni ai limiti Egli rimane nell'ambito della trave soddisfacente le "simple support conditions" e conclude intravedendo possibili estensioni alle travi ed alle piastre di materiale elastico viscoso.

Kaliski, Sylwester 4305

Magnetoelastic vibration of a perfectly conducting cylindrical shell in a constant magnetic field. (Polish and Russian summaries)

Arch. Mech. Stos. **15** (1963), 197–208.

From the author's introduction: "The author [Proc. Vibration Problems **3** (1962), 225–234] gave equations and certain solutions of the equations for flexural vibrations of a perfectly conducting plate in an originally constant magnetic field. Assuming as a starting point that the principle of plane sections is satisfied, we obtained generalized equations of motion of the plate expressed in terms of the function of the deflection surface, $w(x, y, t)$ and the Maxwell surface stress tensors expressing the action of the electromagnetic field (of the vacuum) below and above the plate. The investigation of such plates gives a number of qualitatively new effects. The object of the present paper is to build up analogous equations for perfectly conducting cylindrical shells in an originally constant magnetic field."

Propagation of non-linear visco-elastic waves in rods. (Russian. Azerbaijani summary)

Izv. Akad. Nauk Azerbaĭdžan. SSR Ser. Fiz.-Mat. Tehn. Nauk **1963**, *no.* 6, 17–25.

The paper deals with the propagation of longitudinal waves when the sound velocity depends on deformation. Considering a semi-infinite cylindrical rod, a system of hyperbolic partial differential equations describing the motion is written. The case of longitudinal impact with constant velocity on a non-deformed rod is treated in detail. In particular, the elasticity modulus is taken to be constant for the strain in the interval $(0, e_1)$ and is decreasing for $e > e_1$. At the end, the method of determining experimentally the characteristic functions of the solution is given.

Chandrasekhar, S. 4312

Propagation of elastic waves in liquid crystals.

Proc. Roy. Soc. Ser. A **281** (1964), 92–98.

Author's summary: "The model proposed by Maxwell for a visco-elastic medium is generalized by combining the properties of a crystalline solid and an anisotropic fluid. The basic equations are derived taking the elastic constants and the coefficients of viscosity both to be tensors of rank four. Expressions are given for the complex velocity of propagation of elastic waves of small amplitude as a function of direction. The theory is then applied to the 'stepped drop' (goutte à gradins) discovered by Grandjean, which consists of a number of exactly parallel layers, each layer terminating in a sharp step. The layers slide over one another very easily, but in any other direction the drop is extremely viscous. It is shown that for vibrations of frequency less than $10^9 s^{-1}$, only the longitudinal wave is propagated normal to the layers, the two transverse waves being heavily damped. In the plane of the layers the longitudinal wave and one transverse component are propagated."

S. C. Hunter (Sevenoaks)

Chu, Boa-Teh 4313

Finite amplitude waves in incompressible perfectly elastic materials.

J. Mech. Phys. Solids **12** (1964), 45–57.

Author's summary: "Propagation of finite amplitude plane shear waves in an incompressible perfectly elastic material is considered. The material occupies the half-space, $X_2 \geq 0$, and is initially at rest. A translational motion is imparted to the surface $X_2 = 0$ by applying a spatially uniform and time-dependent shear stress on this surface. The subsequent deformation and change of state in the material are calculated. Two special problems are considered in detail. In the first, the material is in a stress-free state and the surface $X_2 = 0$ is given a uniform motion for time $t > 0$. In the second, the unloading problem following the removal of the applied stress is calculated. The loading and unloading processes in the material generally follow a distinctly different pattern. Depending on the nature of the material and the loading programme, the shear waves may or may not coalesce into a transverse shock wave. The influence of materials of different nature on the propagation of shear waves is also discussed."

Eason, G. 4314

On the torsional impulsive loading of an elastic half space.

Quart. J. Mech. Appl. Math. **17** (1964), 279–292.

Author's summary: "The axisymmetric torsional impulsive loading of an elastic half-space is considered. A general solution is obtained using integral transforms, and three particular types of surface loading are considered in detail. The displacement is determined at all points of the body, and numerical results for the surface displacement are presented in graphical form."

W. D. Collins (Manchester)

Payton, R. G. 4315

Shock-wave propagation in solid and compactible media.

J. Acoust. Soc. Amer. **35** (1963), 525–534.

Plane waves are considered in a medium which compacts under small pressure from density ρ_0/a to ρ_0, and then compresses according to the law: pressure $P = A[(\rho/\rho_0)^\gamma - 1]$, A and γ constants. Shock and characteristic relations are given, and the solution for a rectangular pulse of pressure on the surface of a semi-infinite body is determined. Change to characteristic variables gives linear partial differential equations which are solved numerically. For $\gamma = 3$, linear characteristics permit evaluation by quadratures.

The successive development of homogeneous regions, simple waves, and general waves has been given previously for a closely related solution by H. F. Bohnenblust. Euler coordinates are used in the present paper, and the reviewer suggests that Lagrange coordinates, giving a fixed value at the surface, might lead to a simpler solution.

Berg, Charles A. 4316

Deformation of free boundaries in plane viscous creep. (German summary)

Z. Angew. Math. Phys. **15** (1964), 300–306.

The author considers the plane strain deformation under

conditions of linear viscoelasticity of a material with a hole (stress-free boundary), when stressed uniformly at infinity. The material plane is mapped via a suitable conformal transformation so that the hole is mapped into a circle. For an arbitrary hole the mapping function, which is developed following a procedure due to Muskhelishvili, in polynomial form, requires an infinity of terms. In an example the author considers the case of a mapping function with three terms, in which case the stress-free boundary may have the form of an almost equilateral triangle or of a slightly imperfect ellipse.

S. J. Tupper (Sevenoaks)

Biot, M. A.; Pohle, F. V. 4317

Validity of thin-plate theory in dynamic viscoelasticity.

J. Acoust. Soc. Amer. **36** (1964), 1110–1117.

Explicit solutions to the exact equations of three-dimensional dynamic elasticity can be found for a plate with normal loadings $\sigma_{yy} = \pm q \cos lx \exp(i\omega t)$ on its surfaces $y = \pm h$. The correspondence principle gives the solution for viscoelastic plates. Analogous approximate solutions can be found from thin plate theory, which theory also yields explicit solutions for a much wider class of surface loadings. The object of this paper is to estimate the accuracy of the latter theory by calculating the amplification factor at resonance, an important value in practice, from the two theories. For two examples of viscoelastic material, the authors find that the factors are identical for zero-thickness wavelength ratio, but that the approximate factor is larger as the ratio increases; it is of the order of 10 percent greater for a ratio $1/\pi$.

D. R. Bland (Manchester)

Distéfano, J. N. 4318

Sulla congruenza delle deformazioni in solidi viscoelastici non-omogenei.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 285–290.

The author considers an isotropic solid subjected to external body forces. Part of its surface can be subjected to restrictions which hinder the motions in certain directions. In order that a state of total deformation be congruent (in the sense given by Colonetti) it is necessary that $\int_V \varepsilon_{ij}(t)\delta\sigma_{ij}\,dV = 0$, $\alpha\delta\sigma_{ij}$ being co-actions and V the body volume.

In the linear theory one may prove that in order that the elastic deformations be congruent it is necessary and sufficient that a state of co-actions should not exist and the viscous deformations be congruent. Then it is deduced that the necessary conditions for the congruence of elastic deformations in the absence of the co-actions are $f_1 = f_2$, $\alpha = \text{const}$, f_1, f_2 being the longitudinal and transverse creep functions. With the aid of these results a series of consequences are deduced. *M. Mişicu* (Bucharest)

Distéfano, J. N. 4319

Ancora sulla stabilità asintotica delle deflezioni di una trave viscoelastica.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 504–508.

The author considers the asymptotic stability criterion of viscoelastic theory. Thus, by imposing the condition of asymptotic creep independently of any particularization of the creep functions, the ultimate load is $P/(1+E\gamma_0)$, where P is the elastic critical force, E the elasticity modulus and γ_0 the asymptotic value of the specific creep function $\ell_0(t_0, \tau)$ (for $\tau \to \infty$). *M. Mişicu* (Bucharest)

Soluzioni asintotiche di sistemi di equazioni integrali di Volterra relative a strutture iperstatiche con comportamento viscoso. Applicazione al caso delle travate continue con appoggi cedevoli in modo elasto-viscoso.

Ist. Lombardo Accad. Sci. Lett. Rend. A **97** (1963), 216–273.

In the first part of the paper systems of Volterra integral equations are considered in connection with the constitutive laws of the linear viscoelasticity. For different integral kernels, the known rheological models are analyzed. In the second part some considerations are elaborated in order to establish the asymptotic values of the solutions for different models. The results are applied to a continuum rod with viscoelastic supports.

The paper presents a systematization of certain theoretical and physical elements.

M. Mişicu (Bucharest)

Rogers, T. G.; Lee, E. H. 4323

The cylinder problem in viscoelastic stress analysis.

Quart. Appl. Math. **22** (1964), 117–131.

The problem of a rotating hollow linear viscoelastic circular cylinder, subjected to internal pressure and encased in an elastic shell, is treated on a quasi-static basis. Plane strain and cylindrical symmetry are assumed, but varying angular velocity and an ablating inner

surface are allowed. A general integral representation of the viscoelastic stress-strain relations is used, in contrast to the simple differential operator relations previously considered, and the problem is reduced to a pair of inter-related integral equations of convolution type. Solutions are obtained numerically by means of a high-speed computer, and accuracy assessed by comparison with a simple case solved analytically. The numerical method allows use of arbitrary viscoelastic functions, either from models or experimental data, as well as arbitrary angular velocity and applied pressure histories. Several examples are given to demonstrate the effects of compressibility, different viscoelastic behaviour, spin and pressure histories, and elastic casing properties.

Zelenskiĭ, V. B. 4324

An analogue of the Flaman problem for a pre-stressed visco-elastic medium. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1963**, *no.* 6 (37), 58–63.

Conditions of plane strain are produced in a visco-elastic half-space by applying a uniform normal line-load to the surface. The medium is assumed to have a homogeneous initial stress given by a non-zero direct component of stress in the direction parallel to the surface and perpendicular to the line-load. The problem is tackled using the equations of M. A. Biot [Quart. Appl. Math. **17** (1959), 185–204; MR **21** #5340], and the solution is particularized for a Voigt type of material. Since the material is time-dependent, and the surface load is taken as constant in time, the calculated stresses in the material approach infinity for large values of time. This would appear to place a severe handicap on the applicability of the results. *F. J. Lockett* (Sevenoaks)

Hodge, Philip G., Jr. 4325

Plastic plate theory.

Quart. Appl. Math. **22** (1964), 74–77.

An analysis is given for the determination of the mathematical type (i.e., according to the theory of characteristics) of the system of field and constitutive equations for the elementary bending theory of plane, isotropic, thin plates undergoing perfectly plastic flow. It is proved that, except for special types of yield conditions, the system is fully elliptic. The exceptions apply for piece-wise linear yield curves and also for corners of yield curves, and then the type is various (viz., elliptic or parabolic or hyperbolic), according to the precise circumstances; thus, for example, the results obtained earlier by the reviewer [Proc. Roy. Soc. London Ser. A **241** (1957), 153–179; MR **19**, 342] for Tresca's yield curve are recovered. The present analysis follows the general method of procedure given, for example, by R. Courant and K. O. Friedrichs [*Supersonic flow and shock waves*, § 22, Interscience, New York, 1948; MR **10**, 637] whereas the reviewer's [loc. cit.] analysis proceeds somewhat differently. The results obtained emphasize once again the mathematical advantages expected to accrue from the artifice of the deliberate choice of piece-wise linear yield curves (or surfaces) in the solution of plasticity problems.

Drucker, D. C. 4326

On the postulate of stability of material in the mechanics of continua.

J. Mécanique **3** (1964), 235–249.

In view of certain criticism, the author once more takes up the problem of the stability postulate for time-independent and time-dependent materials. In particular, it is agreed that convexity of the yield surface and normality of the vector of permanent strain increment will, at least in principle, no longer be true for materials whose elastic moduli vary with plastic strain.

The severe restrictions imposed by the stability requirement on time-dependent materials are discussed.

A linearized theory of nosing of shells.

Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 535–539.

Author's summary: "The problem of nosing of shells in finite plastic strain is analyzed by considering various methods of jointly linearizing yield condition and flow rule. The numerical results show that excellent approximations to the predictions of von Mises' theory can be obtained."

Chang, C. H.; Liu, C. K. 4330

Solutions of plane problems in dynamic thermoelasticity.

Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 543–546.

From the authors' introduction: "In the present work, solutions of the dynamic response of a two-dimensional problem concerning isotropic elastic solids subjected to a prescribed temperature field and time-dependent boundary conditions are presented. The latter may arise from the varying temperature and the prescribed pressure functions at the boundaries. The problem is solved by the classic

method of separation of variables in conjunction with the method of Mindlin and Goodman for the treatment of the time-dependent boundary conditions."

Datta, Subhendu K. 4331

Steady state thermal stresses in an elastic solid bounded by two cones. (German summary)

Z. Angew. Math. Phys. **15** (1964), 175–183.

The author applies similarity transformations to a steady-state thermoelastic problem of a solid bounded by two coaxial circular cones, where the surface tractions vanish identically and the distributions of the surface temperature vary according to arbitrary powers of the distance from the apex, and obtains stress formulas in terms of Legendre functions. Numerical results are presented for a case in which the two surfaces are maintained at different constant temperatures. {The author informed the reviewer that σ_R, σ_φ and $\tau_{R\varphi}$ in Figure 3 should be replaced by σ_R/β, σ_φ/β and $\tau_{R\varphi}/\beta$, where β is defined by (4.4) in the paper, and the numerical calculation is carried out for Poisson's ratio $\nu=1/4$ (which is not stated in the paper).}

Herrmann, George 4332

On second-order thermoelastic effects. (German summary)

Z. Angew. Math. Phys. **15** (1964), 253–262.

In order to investigate temperature changes in a body subject to shear, the author extends Biot's second-order theory of elasticity to include thermal effects. Numerical results are given based on values of elastic constants measured by Poynting in his famous tests with steel piano wires. However, in the reviewer's opinion, these values should be accepted with caution since the elastic limit may have been exceeded in the tests. *H. Parkus* (Vienna)

Fluid mechanical aspects of antisymmetric stress.

Phys. Fluids **7** (1964), 842–854.

Authors' summary: "Basic fluid mechanical concepts are reformulated in order to account for some structural aspects of fluid flow. A continuous spin field is assigned to the rotation or spin of molecular subunits. The interaction of internal spin with fluid flow is described by antisymmetric stress while couple stress accounts for viscous transport of internal angular momentum. With constitutive relations appropriate to a linear, isotropic fluid we obtain generalized Navier-Stokes equations for the velocity and spin fields. Physical arguments are advanced in support of several alternative boundary conditions for the spin field. From this mathematical apparatus we obtain formulas that explicitly exhibit the effects of molecular structure upon fluid flow. The interactions of polar fluids with electric fields are described by a body-torque density. The special case of a rapidly rotating electric field is examined in detail and the induction of fluid flow discussed. The effect of a rotating electric field upon an ionic solution is analyzed in terms of microscopically orbiting ions. This model demonstrates how antisymmetric stress and body torque can arise in 'structureless' fluids."

Ertel, H. 4334

Differentialoperationen der Hydrodynamik in Form Lagrangescher Klammersymbole.

Monatsb. Deutsch. Akad. Wiss. Berlin **5** (1963), 218–220.

The author considers various forms of the equations of motion of an incompressible fluid. By forming the curl of the equations of motion, expressed in terms of the velocity vector, and by using the continuity equation, the well-known relation for the vorticity vector is obtained. Multiplying both sides of this last equation by the generalized Kronecker tensor and then differentiating, the author obtains a relation between the skew-symmetric product of the first derivatives of the velocity and vorticity vectors (the Lagrange bracket) and the curl of the total time derivative of the vorticity vector. A modification of the vorticity for the compressible (isentropic) case is noted and is compared to the result of K. Oswatitsch [*Handbuch der Physik*, Bd. VIII/1, pp. 1–124, Springer, Berlin, 1959; MR **21** #6836a].

Ertel, H. 4335

Äquivalente Wirbel-Differentialgleichungen der Hydrodynamik.

Monatsb. Deutsch. Akad. Wiss. Berlin **5** (1963), 689–692.

The study of the differential equations for the vorticity vector, initiated by the author in a previous paper [#4334 above] is continued for the case in which the external force has a potential and the fluid is incompressible or isentropic compressible. Three forms of the differential equation are obtained by use of (1) the generalized Kronecker tensor; (2) the deformation velocity tensor. Further, a symbolic scheme for writing one of these equations (in a form suitable for computation) is given. *N. Coburn* (Ann Arbor, Mich.)

Rotating flows of von Kármán and Bödewadt.

Phys. Fluids **7** (1964), 867–875.

The flow engendered by a rotating disc in a fluid otherwise at rest (von Kármán flow) and by a fixed disc in a fluid rotating at infinity (Bödewadt flow) are considered anew.

In each case the problem is reduced to the solution of

a set of ordinary differential equations containing a parameter R, obtained after an unusual procedure. The equations reduce to standard forms as $R\to\infty$. Numerical solutions of each problem are obtained for various values of R and it is pointed out that for Bödewadt's problem "when $R\geq 9$ no proper nonoscillating flows exist".

Homogeneous helical motion in a cone.

Prikl. Mat. Meh. **25** (1961), 140–145 (*Russian*); *translated as J. Appl. Math. Mech.* **25** (1961), 193–201.

The motion of a perfect incompressible fluid inside a finite right circular cone covered with a spherical cap is considered. Solutions are found for steady axisymmetric flows with azimuthal swirl when the fluid is injected along the perimeter of the cap as a source flow with finite azimuthal velocity, and removed through two sinks located at the apex and at the center of the cap. The partial differential equation satisfied by the stream function is solved by separation of variables, and contains two arbitrary constants, one of which specifies the vorticity in the flow. Since no effort is made to consider the effects of viscosity, it seems unrealistic to this reviewer to introduce any distributed vorticity unless the cone is infinite or regions of closed streamlines are anticipated. The result for potential motion is given, and a streamline pattern for non-zero vorticity is shown. Although the singularities of the separated solution on the spherical cap have not been studied, the mathematical analysis is interesting and should be of use in treating other flow problems in cones. {A number of misprints confuse k and κ.}

Short surface waves in the presence of a finite dock. I, II.

Proc. Cambridge Philos. Soc. **60** (1964), 957–983; *ibid.* **60** (1964), 985–1011.

From the author's summaries: "In the first part, a long thin plate of finite width (a finite dock) extends over part of the otherwise free surface of a semi-infinite body of water under gravity and is given a forced heaving motion of small amplitude about this position. The solution of the boundary-value problem for the velocity potential of the resulting forced (two-dimensional) surface wave motion may be reduced to that of an integral equation of the second kind for the value of the potential on the dock by means of an appropriate Green's function. There is an infinite number of choices for such a Green's function, and we show below how to construct one for which the kernel of the corresponding integral equation tends to zero with the ratio: wavelength/dock-width. The integral equation may then be solved by iteration to calculate the short-wave asymptotics of the original wave-making problem.

"In the second part, the generalized wave-making problem for the forced high-frequency oscillations of a finite dock is solved through use of the Green's function obtained in the first part of this paper. The specific cases of heave and roll are considered with particular reference to the forces on the dock and the amplitude and phase of the radiated waves. These results are then utilized to solve the problem of transmission of short waves under a fixed dock."

Sretenskii, L. N. [Sretenskiĭ, L. N.] 4343

Periodic waves generated by a source located above a sloping bottom.

Prikl. Mat. Meh. **27** (1963), 1012–1025 (*Russian*); *translated as J. Appl. Math. Mech.* **27** (1964), 1557–1576.

The author investigates the two-dimensional linearized waves excited on the surface of a fluid by a periodic output source located arbitrarily on a constant slope bottom. The mathematical analysis is for bottom slopes which are integral fractions of $\pi/2$. Detailed applications are presented for slopes of $\pi/2$, $\pi/6$, and $\pi/8$. For a bottom slope of $\pi/4$ it is shown how to determine the depths at which a periodically oscillating source will not transmit progressive surface waves to infinity.

Chabert d'Hières, Gabriel; Gouyon, René; Kravtchenko, Julien 4345

Contribution à la théorie du clapotis plan.

J. Math. Pures Appl. (9) **43** (1964), 1–25.

The theory of steady plane free-surface flows of a heavy inviscid fluid which satisfy the exact free-surface condition has been the subject of a long series of papers in which the existence of periodic and other gravity waves has been established under a variety of conditions. The situation is quite different with standing waves. Even in the simplest situation no existence (or non-existence) proofs are available. The authors address themselves to this problem. Although they do not solve it, their treatment is clearly intended to provide the basis for an existence proof.

The problem is formulated for fluid of finite depth in terms of variables of Lagrangian type. It is assumed that the variables describing the particle motion and the period can be expanded in a power series in a small parameter of the same order as the wave amplitude. The equations to be satisfied by the nth-order coefficients are found explicitly and solved. What is still lacking, of course, is the proof that the series has a finite radius of convergence. However, assuming this, one can draw several conclusions: (1) The motion is irrotational; (2) the particle paths are arcs along which the particles move back and forth, all coming to rest simultaneously at each end. A final section gives more detailed results for solutions accurate to the third order. The relation of the results of this paper to earlier ones on the subject is also discussed. *J. V. Wehausen* (Berkeley, Calif.)

Penetration of a cone into an incompressible non-uniform liquid. (Russian. Armenian summary)

Izv. Akad. Nauk Armjan. SSR Ser. Fiz.-Mat. Nauk **16** (1963), no. 5, 83–90.

The problem considered is that of a cone impinging on the free surface of a stratified fluid. The cone is assumed to have a small slope, and the linearized free surface condition is approximated by the condition of vanishing velocity potential. The fluid density is assumed to be an exponential function of the vertical coordinate. Analytic and numerical results are obtained for the potential, pressure, impulsive force during impact, and velocity of the cone. Comparison is made with the case of a uniform fluid density. *J. N. Newman* (Washington, D.C.)

Moiseev, N. N. 4347

Introduction to the theory of oscillations of liquid-containing bodies.

Advances in Applied Mechanics, Vol. 8, *pp.* 233–289. *Academic Press, New York,* 1964.

This review paper deals with a problem of rapidly increasing technological interest in a clear and authoritative manner. The treatment is restricted to linear oscillations of conservative systems and makes extensive use of the classical tools for such systems; in particular, Hamilton's principle forms the starting point, and the calculation of the Lagrangian the primary step, in the treatment of each of the individual problems. The first part of the paper surveys the special problems of: (1) free-surface oscillations in a fixed container; (2) a rigid body containing a cavity completely filled with liquid (the "Stokes-Zhukovskii problem"); (3) a pendulum that comprises a rigid rod and a rigid, open vessel of liquid; (4) a system that comprises a liquid-filled cavity with a free surface and has only a finite number of degrees of freedom in the absence of liquid motion; (5) torsional oscillations of a Bernoulli beam with a cavity that is either completely or partially filled; (6) flexural-torsional oscillations of the last configuration. Part II deals with the general properties of the equations that describe the foregoing systems. Perhaps the most interesting result is that a necessary and sufficient condition for the stability of the equilibrium of a system of solid bodies that contains liquid with a free surface is that an equivalent system of solid bodies be stable, even though the two systems cannot be dynamically equivalent in consequence of the free-surface oscillations [as originally established by both Stokes and Zhukovskii, dynamical equivalence is possible for problems of category (2) above].

Formulas for the general solutions of the Oseen equations in cylindrical and spherical coordinates. (Russian)

Akad. Nauk Uzbek. SSR Trudy Inst. Mat. No. 23 (1961), 65–91.

The author points out that solutions for the pressure and the velocity in the case of Oseen's equations can be found in terms of ω, where ω satisfies

$$\left[\frac{\partial}{\partial t}+(\mathbf{c}\cdot\nabla)-\nu\nabla^2\right]\nabla^2\omega = 0.$$

Most of the pages in this paper are devoted to calculating various vector operations in cylindrical and polar coordinates. For instance, in spherical polars $(\mathbf{c}\cdot\nabla)\nabla^2\omega$ contains over 130 terms. In each coordinate

system a specimen general solution is constructed by taking the components of ω to be harmonic functions. As this amounts to saying that the vorticity is everywhere zero, these solutions are of little physical significance. A much more concise and illuminating theory is given in Lamb [*Hydrodynamics*, sixth edition, p. 610, Dover, New York, 1945], whilst explicit solutions are contained in Goldstein [Proc. Roy. Soc. London Ser. A **123** (1929), 225–235] and Tomotika and Aoi [Quart. J. Mech. Appl. Math. **3** (1950), 140–161; MR **12**, 59].

Lower bounds to thermal instability criteria of completely confined fluids inside cylinders of arbitrary cross section.
Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 376–379.
Author's summary: "A method is developed to compute the lower bounds for the thermal instability criterion (the critical Rayleigh number) for fluids completely confined inside cylinders of arbitrary cross-section; i.e., Rayleigh numbers below which no spontaneous flow may occur in spite of the density gradient being opposite to the body force direction."

Szablewski, Witold 4354
Querwirbelartige Störungen der laminaren Grundströmung im Innern und Äussern eines rotierenden Zylinders. (English summary)
Z. Angew. Math. Phys. **15** (1964), 107–115.
The author considers a novel variation of the classical linearized hydrodynamic stability problem for flows with curved streamlines. In particular, he examines the case of an infinite rotating circular cylinder both inside and outside the separating boundary. Moreover, the solutions for disturbances are explicitly evaluated without resort to the usual assumption of axisymmetry. The results of this work indicate the importance of transverse vortices of the type which are common to the parallel flow problem. Perturbations may also have a non-zero phase velocity. Finally, some special cases are discussed and depicted by graphs of the streamlines.

Flow of a radiating gas in the vicinity of the critical point of a blunt-nosed body. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **19** (1964), *no.* 3, 103–109.

Author's summary: "The problem of motion of viscous radiative gas flow near the stagnation point of a blunt-nosed body is considered by Cherny-Freeman's method. The problem is reduced to resolving a single non-linear integro-differential equation for the gas enthalpy. This equation is transformed to an integral equation, the solution of which is suggested by iterations. The method permits one to obtain the surface body temperature."

Tao, L. N. 4360

On the variational principle and Lagrange equations in studies of gasdynamic lubrication.

Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 43–46.

The paper presents the variational formulation of hydrodynamic lubrication by taking into account the compressibility. Supposing a permanent motion, it is shown that the Reynolds equation is equivalent to a variational expression; then a set of partial differential equations in generalized coordinates is derived. Furthermore, from Hamilton's principle, the Lagrangian and dissipation-production densities are established, and the incompressible case is obtained as a particular problem. Thus the paper succeeds in giving a unified variational method for both gas and liquid lubrication.

{In spite of the attractive mathematical treatment, the reviewer's opinion is that for compressible lubricants the method is almost too difficult to use in numerical computations; for incompressible fluids some similar calculations were already performed by Weber [Z. Angew. Math. Mech. **30** (1950), 112–120; MR **11**, 751].}

On some mathematical aspects of the boundary layer theory. (Romanian and Russian summaries)

An. Şti. Univ. "Al. I. Cuza" Iaşi Secţ. I (N.S.) **7** (1961), 345–397.

A general discussion, mostly expository, of questions of existence of solutions to problems in the boundary layer theory. The author's basic theme is an association of partial differential equations with ordinary ones in accordance with his development of the theory of A. D. Michal [Proc. Nat. Acad. Sci. U.S.A. **37** (1951), 623–627; MR **13**, 251] and A. J. A. Morgan [Quart. J. Math. Oxford Ser. (2) **3** (1952), 250–259; MR **15**, 37]. Related results by the author may be found in Inter. Sympos. Nonlinear Differential Equations and Nonlinear Mechanics, pp. 221–240, Academic Press, New York, 1963 [MR **26** #6551] and in J. Reine Angew. Math. **206** (1961), 175–191; ibid. **207** (1961), 113–128 [MR **26** #981].

Leslie, F. M. 4362

The stability of Couette flow of certain anisotropic fluids.

Proc. Cambridge Philos. Soc. **60** (1964), 949–955.

The author discusses the stability of the flow of anisotropic fluids with preferred direction between concentric, rotating cylinders when the gap is small and the cylinders are rotating in the same direction. A small perturbation is given both in velocity and in preferred direction.

He makes the following assumptions in his analysis: (i) $\mu_1=0$; (ii) $\mu>0$, $\mu_2>0$, $\mu_3>0$, $2(3\mu+\mu_3)>\mu_2$; (iii) the gap is small; (iv) the angular velocity of the primary flow, which occurs in a coefficient of the differential equation in $v(r)$, is replaced by an average value, thereby reducing the equation to one with constant coefficients; (v) the function $v(x)$, $x=(r-R_1)/(R_2-R_1)$, R_1, R_2 being two radii, and its derivatives up to order six can be represented by Fourier series. He concludes that whatever be the sign of the parameter λ, the solution of the steady-state equations for which $N_1>0$, $N_2>0$ is always more stable than the one for which $N_1>0$, $N_2<0$, where $N_1^2=\frac{1}{2}(\lambda-1)/\lambda$, and $N_2^2=\frac{1}{2}(\lambda+1)/\lambda$. This does not, however, contradict the reviewer's results [Arch. Rational Mech. Anal. **10** (1962), 101–107; MR **26** #7247], which are obtained on the basis $\mu_1\neq 0$ and without making any one of the above assumptions. In fact, if $\mu_1=0$, the fluid does not behave like a Bingham plastic material. The reviewer's results show exactly the same thing obtained here, provided that $\mu_1=0$ is imposed on his solution. The author justifies taking $\mu_1=0$ by just quoting Green [Proc. Cambridge Philos. Soc. **60** (1964), 123–128; MR **29** #827], who has himself given constitutive equations for anisotropic fluids, which are, no doubt, slightly different from those of Ericksen [Arch. Rational Mech. Anal. **4** (1960), 231–237; MR **22** #1274], but which do not make stress reduce to hydrostatic pressure when the rate of strain vanishes. *P. D. S. Verma* (Kharagpur)

Rayleigh-Taylor instability for compressible fluids.

Phys. Fluids **7** (1964), 862–866.

The stability problem of an accelerating contact surface separating two inviscid, compressible fluids is examined. The governing equations for the linearized perturbed motion are derived and then simplified by the assumption of a quasisteady state. The limiting case of small wave length disturbances shows that the interface is unstable when the slope of the unperturbed pressure decreases in the direction of increasing pressure and is stable otherwise. This agrees with the result of two incompressible fluids in a gravitational field by Taylor [Proc. Roy. Soc. London Ser. A **201** (1950), 192–196; MR **12**, 58]. Also, in the particular case of constant acceleration and static isothermal equilibrium, the result remains the same qualitatively as for two incompressible fluids.

Contribution to the theory of cellular thermal convection.

J. Fluid Mech. 19 (1964), 353–365.

A motionless conductive state is possible in a horizontal fluid layer heated from below. Refining the work of Palm [same J. 8 (1960), 183–192], the reviewer and Stuart showed [ibid. 13 (1962), 289–306; MR 25 #3659] that the nonlinear interaction of two particular disturbance modes of the same horizontal wave-number could result in hexagonal convection cells if the difference between the actual and critical Rayleigh numbers was sufficiently small compared to a dimensionless measure of the viscosity variation with temperature. When only these two modes are considered, another stable configuration is possible, but the authors' elegant argument shows that it is unstable when a certain third mode is considered. Whether or not new stable equilibrium points occur when more than two disturbance modes are allowed is left open here (but is resolved in a forthcoming paper of the reviewer). The authors find the hexagonal cell to be stable to all infinitesimal disturbances of the same horizontal wave number. *L. A. Segel* (Troy, N.Y.)

Csanady, G. T. 4368

Turbulent diffusion in a stratified fluid.

J. Atmospheric Sci. 21 (1964), 439–447.

The author considers the dynamical effects on a particle drifting in a homogeneous turbulent fluid field which is stationary and uniform except for a constant vertical density gradient. The author makes several order-of-magnitude estimates regarding the characteristics of the turbulent field in which the diffusion takes place. In the model considered here, it is the initial hypothesis that the vertical gradient of mean potential temperature is constant, and according to the author, this model applies approximately to many practical situations, simple compared to a neutral atmosphere. Further, in the equation of energy there has been an ad hoc assumption regarding a diffusion term from dimensional reasoning to avoid complexity of the theory. The author finds adequate evidence to establish the qualitative correctness of his theoretical model. *K. M. Ghosh* (Belgharia)

Kraichnan, Robert H. 4369

Direct-interaction approximation for shear and thermally driven turbulence.

Phys. Fluids 7 (1964), 1048–1062.

Author's summary: "The direct-interaction approximation for turbulence is extended to shear flows and Boussinesq convection contained in regions of arbitrary size and shape. It is pointed out that the approximation provides a consistent generalization of mixing-length concepts which continues to be applicable when the scale of inhomogeneity is comparable to the effective mixing length. The degree of faithfulness to be expected of the approximations is discussed on the basis of inferences from numerical results on isotropic turbulence."

Meecham, William C.; Siegel, Armand 4370

Wiener-Hermite expansion in model turbulence at large Reynolds numbers.

Phys. Fluids 7 (1964), 1178–1190.

Les auteurs se proposent de représenter les solutions aléatoires de certaines équations fonctionnelles non linéaires par des expressions exactes au lieu de se borner à calculer, suivant les méthodes classiques, quelques uns de leurs moments. Ils utilisent les développements en fonctionnelles de Wiener-Hermite. L'élément de base est la fonction aléatoire gaussienne $a(x)$, de moyenne nulle, ayant pour covariance $\langle a(x_1)a(x_2)\rangle = \delta(x_1 - x_2)$. On en déduit par convolution une fonction gaussienne régulière

$$f(x) = \int K(x-x')a(x')\,dx'.$$

On construit ensuite une famille statistiquement orthonormale de fonctions aléatoires

$$H^0(x) = 1, \qquad H^1(x) = a(x),$$
$$H^2(x_1, x_2) = a(x_1)a(x_2) - \delta(x_1 - x_2), \text{ etc.,}$$

et l'on représente la fonction cherchée $u(x)$ par une somme d'intégrales de convolution de H^0, H^1, H^2, par des noyaux $K^{(1)}$, $K^{(2)}$, $\cdots$. On note que cette forme de noyaux assure d'avance l'homogénéité. On cherche si $u(x)$, ainsi représentée, peut être solution de l'équation de Burgers (sans dimensions)

$$\frac{\partial u}{\partial t} + u\frac{\partial u}{\partial x} - \frac{1}{R}\frac{\partial^2 u}{\partial x^2} = 0.$$

En substituant, et en ne prenant qu'un nombre fini de termes dans le développement de u, on obtient un ensemble d'équations intégro-différentielles, dont la première relie

les noyaux $K^{(1)}$, $K^{(2)}$ et conduit pour la fonction spectrale énergétique $E(k,t)$ à l'équation

$$\frac{\partial E}{\partial t} = -\frac{2}{R}k^2E - k^2\int [2E(k,t)E(k_1,t) - E(k-k_1,t)E(k_1,t)]\,dk_1.$$

Sa transformée de Fourier Q est telle que

$$\frac{\partial}{\partial t}q - \frac{\partial^2}{\partial r^2}q^2 = -\frac{2}{R}\frac{\partial^2}{\partial r^2}q(0,t),$$

avec $q = Q(0,t) - Q(r,t) + 1/R$. On vérifie que

$$\int_{-\infty}^{\infty} Q(r,t)\,dr = \text{const.}$$

Le résultat dimensionnel de Kolmogoroff ($E_k \sim k^{-5/3}$) n'est pas vérifié ici.

On sait obtenir des solutions de la forme $Q(r,t) = \Lambda(tr^{-2})$, mais elles sont d'interprétation peu physique. Le calcul de Q et de E a été fait par des méthodes numériques, pour $R = 100$ et successivement

$$Q(r,0) = e^{-r^2} \quad \text{et} \quad Q(r,0) = \frac{1}{1+\pi r^2},$$

d'où $E(0,t) = (4\pi)^{-1/2}$.

Les résultats sont très voisins, malgré la différence de forme des conditions initiales, et présentent une analogie sérieuse avec les résultats expérimentaux relatifs à la turbulence. On en conclut à l'existence d'une forme d'équilibre pour Q, et à la rapide convergence probable du développement de u. *J. Bass* (Paris)

Lumley, John L. 4371

Turbulence in non-Newtonian fluids.

Phys. Fluids 7 (1964), 335–337.

The motion and shearing properties of a Reiner-Rivlin body in turbulent regime are studied. Using the general form for the stresses, established by Truesdell, the dissipation function is written by means of the Fourier transformation and wave number vector. Then the case when the distribution of the turbulent shearing stresses is Gaussian is examined, and it is shown that the energy dissipation occurs as in a Newtonian fluid with an effective viscosity dependent on the mean-square shear.

If the effective viscosity is low, the dissipative terms sufficiently small and the wave number large, one obtains an inertial sub-range whose mean values are characterized by ε, the dissipation, and the wave number only. The behaviour for small shear and small dissipation is also analyzed. As a conclusion the viscoelastic effects are responsible for some anomalies observed in high-molecular-weight linear polymers, and the form of the probability density of the strain tensor is quite sensitive to the form of the stress-deformation relation.

The author presents some new interesting ideas and results in the field of turbulence in non-Newtonian fluids. Neither diagrams nor experimental data are given.

On the rotational motion of a sphere in a rarefied flow of high velocity. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. 19 (1964), no. 3, 162–167.

The author considers the rotation motion of a sphere relative to its center of inertia in a rarefied gas flow having high velocity (in comparison with the thermal motion of molecules). It is assumed that the rarefied gas is such that the free path of molecules exceeds the dimensions of the body considered in such a way that the hydrodynamic methods are not applicable.

Several particular solutions are given for Euler's equations (solid with fixed body) in the case in which the center of inertia coincides with the geometric center of the body and in the case in which these centers do not coincide. *L. Dragos* (Bucharest)

Hosokawa, Iwao 4373

Unified formalism of the linearized compressible flow fields.

Quart. Appl. Math. 22 (1964), 133–142.

The author considers the linearized transonic small perturbation equation

$$(1-M_\infty^2)\varphi_{xx} + \varphi_{yy} + \varphi_{zz} = K\varphi_x,$$

where K is a positive constant. For $K \to 0$ the equation reduces to the conventional linearized subsonic or supersonic potential equation. For $K \neq 0$ the equation is believed to yield approximate transonic solutions in the neighborhood of a suitable class of thin bodies. The author makes use of Schwartz's distribution theory in order to obtain the general solution to the equation, valid both in the elliptic ($M_\infty < 1$) and hyperbolic ($M_\infty > 1$) cases. As an example, the flow about a thin wing is treated in detail, and some new results for the lifting wing are found. Formulas describing operations with distributions are conveniently summarized in an appendix.

Garvine, Richard W. 4376

Hypersonic viscous flow near a sharp leading edge.

AIAA J. **2** (1964), 1660–1661.

A great deal of re-thinking has gone into hypersonic flow problems since it was recognized that it does matter what happens near the leading edge of a body. Generally, it has been found that the reported experimental findings differ greatly from the values predicted by viscous strong interaction theory. The research note here is a theoretical effort which examines the departure under certain practical conditions. The findings indicate that a more complicated viscous flow is involved than that of the strong interaction region concept. *W. O. Criminale, Jr.* (Princeton, N.J.)

Maslen, S. H. 4377

Inviscid hypersonic flow past smooth symmetric bodies.

AIAA J. **2** (1964), 1055–1061.

This paper presents a simple, accurate method for solving the entire hypersonic flow fields over a blunt body. It is primarily an inverse method, and the concepts of thin shock layer are employed. The crucial step lies in the way of obtaining the pressure field approximately from the equation

$$\frac{\partial p(x, \psi)}{\partial \psi} \sim u,$$

where p is the pressure, x the distance along the shock, ψ the stream function, u the x-component of velocity. To determine the pressure, the present method takes $u = u_s(x)$, the u-component immediately behind the shock for the same value of x, while previous authors [W. D. Hayes and R. F. Probstein, *Hypersonic flow theory*, p. 180, Academic Press, New York, 1959; MR 21 #540] usually took $u = u_s(\psi)$, the u-component at the point of entry of the streamline being considered. The latter follows from the consistent approximation, yet becomes very inaccurate downstream near the body. Calculated examples using the present method show excellent agreement in comparison with more exact results. Extension to include the non-equilibrium effects is also discussed.

On the law of motion of a shock wave in fluid. (Russian. Armenian summary)

Izv. Akad. Nauk Armjan. SSR Ser. Fiz.-Mat. Nauk **17** (1964), *no.* 3, 71–80.

The response of a fluid-filled half-space to an expanding ring pressure disturbance on its surface is considered. Specifically, the prescribed surface pressure on points at distance $R(t)$ from point 0 is $P_a(t)$. The fluid is assumed to obey a polytropic pressure-density relation. Approximate expressions for pressure on the shock front in the influence zone of 0 and far from 0 are derived.

Pant, J. C.; Mishra, R. S. 4380

Shock waves of finite thickness in magneto-gas-dynamics.

Rend. Circ. Mat. Palermo (2) **12** (1963), 59–81.

Under the assumption of shock waves of finite thickness, the authors deduce the conservation equations (for normal components of the magnetic field, mass states, momentum states and energy) throughout the thickness of the shock wave. The conservation equations are also obtained when the diffusivities are so small that the discontinuities are not smoothed out very much. A particularization is made for the case in which the conductivity is infinite and the magnetic field is everywhere tangential to the shock surface.

The method employed is based on writing the magneto-hydrodynamic equation for a disk like the cylindrical volume in the thickness of the shock wave.

Jeffrey, Alan 4381

A note on the derivation of the discontinuity conditions across contact discontinuities, shocks and phase fronts. (German summary)

Z. Angew. Math. Phys. **15** (1964), 68–71.

The author studies the discontinuity theory associated with a system of conservation laws. By using an integral form of these laws, the associated Rankine-Hugoniot jump conditions are obtained. The theory is applied to the quasi-linear system of conservation laws determined by the equations of mass, momentum and energy of an inviscid, compressible, heat-conducting fluid in the equilibrium state. It is shown that, in addition to the well-known shock and contact waves, a phase front wave exists. This last wave is characterized by: (1) continuity of the density across the front; (2) the normal component of the velocity of the fluid differs from the normal component of the velocity of the wave front (as is the case for a shock wave); (3) pressure (as in a contact wave) and fluid velocity are continuous across the wave front. These effects are due to the inclusion of the heat conduction term in the energy relation. (Reviewer's note: A similar "integral form" approach to discontinuity theory was given by J. B. Keller [J. Appl. Phys. 25 (1954), 938–947;

MR 16, 761] and another "integral form" approach was given by the reviewer [Math. Mag. 27 (1954), 245–264; MR 15, 1000].) *N. Coburn* (Ann Arbor, Mich.)

Spence, D. A.; Woods, B. A. 4382

A review of theoretical treatments of shock-tube attenuation.

J. Fluid Mech. **19** (1964), 161–174.

The alteration of the ideal constant state flow in a shock tube, due to the viscous effects at the wall, is considered here for the case where the boundary layer is thin compared with the tube diameter. The transient problem in two space dimensions is reduced to a one-dimensional problem by applying small perturbation theory outside the boundary layer. After a further acoustic approximation, an explicit solution is obtained in terms of two arbitrary functions and a function, presumed known, of the boundary layer. It is shown that this solution contains the results of previous work by others (who used physical arguments) dealing with the shock speed and the running time. The finite opening time of the diaphragm and other factors are discussed briefly. The paper contains 32 references to theoretical and experimental work with shock-tube attenuation.

Frater, K. R. 4385

Flow of an elastico-viscous fluid between torsionally oscillating disks.

J. Fluid Mech. **19** (1964), 175–186.

In this paper the author discusses the flow of an incompressible elastico-viscous fluid characterized by the constitutive equations

$$S_{ik} = P_{ik} - Pg_{ik},$$

$$P^{ik} + \lambda_1 \frac{\delta P^{ik}}{\delta T} + \mu_0 P_j^{\ j} \cdot E^{ik} = 2\eta_0\left(E^{ik} + \lambda_2 \frac{\delta E^{ik}}{\delta T}\right)$$

given by Oldroyd [Proc. Roy. Soc. London Ser. A **200** (1950), 523–541; MR 11, 703], where S_{ik} and E_{ik} are, respectively, the stress tensor and the rate of strain tensor; $\delta/\delta T$ denotes the convective time-derivative; g_{ik} is the metric tensor; η_0 is a constant having dimensions of viscosity and λ_1 and λ_2 are the constants having the dimensions of time, between two parallel, infinite disks when one disk is held at rest and the other performs rotary oscillations about their common axis. It is found that the purely periodic primary motion has associated with it a secondary steady velocity distribution as well as a secondary periodic motion with twice the frequency of the primary motion, similar to that predicted by the reviewer and Rajeswari [J. Indian Inst. Sci. **44** (1962), 219–238] for the Rivlin-Ericksen fluids. The author finds that the main difference between the present investigation and that of the reviewer and Rajeswari is that the steady secondary motion always shows reversal above a certain critical Reynolds number in the case of Rivlin-Ericksen fluids, while in the case of incompressible elastico-viscous fluid discussed by the author it shows such a reversal if $\lambda_2/\lambda_1 < \frac{1}{2}$. This difference is attributed to the difference in the nature of these two types of fluids. For example, the Rivlin-Ericksen fluids studied by the reviewer and Rajeswari show retarded response to applied stress but do not show relaxation of stress at constant strain, and the normal stress differences do not correspond to a simple tension along the stream lines in contrast to the Oldroyd fluids discussed in the present paper.

Two dimensional flow of visco-elastic fluids near a stagnation point with large suction. (Polish and Russian summaries)

Arch. Mech. Stos. **15** (1963), 711–717.

The paper deals with the two-dimensional steady flow of incompressible visco-elastic fluids near a stagnation point with large suction. Taking velocity components on the lines of Howarth, the authors substitute in the stress-strain relations $s_j^{\ i} + \tau \dot{s}_j^{\ i} = 2\mu d_j^{\ i}$ and the equations of motion. The final equation is solved by the method of successive approximations. The results, though plotted in the form of curves, are not discussed. Convergence of the series for ϕ for different numerical values of k deserves mention. Some of the basic equations written in tensor form are not quite correct. See, for instance, the equations (1.2) and (1.3),

$$(1.2)\qquad d_j^{\ i} = \tfrac{1}{2}(u_{i,j} + u_{j,i}),$$

$$(1.3)\qquad s_j^{\ i} + \tau \dot{s}_j^{\ i} = 2\mu d_j^{\ i},$$

where

$$\dot{s}_j^{\ i} = \frac{\partial}{\partial t} s_j^{\ i} + s^i_{j,k} v^k - s_k^{\ i} v_{,k}^{\ j} + s_j^{\ k} v_{,k}^{\ i} + s_j^{\ i} v_{,k}^{\ k}.$$

Non-Newtonian effects in some general elastico-viscous liquids.

Second-order Effects in Elasticity, Plasticity and Fluid Dynamics (Internat. Sympos., Haifa, 1962), *pp.* 507–519. *Jerusalem Academic Press, Jerusalem; Pergamon, Oxford*, 1964.

This paper is concerned with the behaviour of elastico-viscous liquids at small rates of shear, based on Oldroyd's theory [Proc. Roy. Soc. London Ser. A **200** (1950), 523–541; MR **11**, 703; Quart. J. Mech. Appl. Math. **4** (1951), 271–282; MR **13**, 303; Proc. Roy. Soc. London Ser. A **245** (1958), 278–297; MR **20** #605]. The author attempts to construct two models of elastico-viscous liquids A' and B' based on a general linear equation of state. The liquids are specified by their respective distribution functions of relaxation times, known as relaxation spectra. Of the two models, the second one has been shown to exhibit all the essential features of observed steady non-Newtonian behaviour with the exception of the observed variation in apparent viscosity with rate of shear. The predicted normal stress effect in the case of flow between a horizontal flat plate and a cone of semi-angle very near to $\frac{1}{2}\pi$ has been shown to be in qualitative agreement with Roberts' experimental results on certain elastico-viscous liquids [Roberts, Proc. Second Internat. Congr. Rheology (Oxford, 1953), pp. 91–98, Academic Press, New York, 1954]. The reviewer agrees with the comment of Truesdell that the liquid models A' and B' constructed by the author are characterised after all by a linear equation of state in the sense of Noll, and hence the entire work of the present author will reduce to a much simpler analysis in accordance with the general solutions for viscometric flows by Coleman and Noll.

Ziegler, H. 4390

Some limiting cases of non-Newtonian fluids.

Progress in Applied Mechanics, pp. 317–332. *Macmillan, New York*, 1963.

A continuation of the author's earlier paper [Progress in Solid Mechanics, Vol. IV, pp. 91–193, North-Holland, Amsterdam, 1963; MR **29** #772]. Four incompressible fluids are considered which are the Bingham material and its three inversions. For creeping motions in these materials the principle of least irreversible force is used to deduce two theorems concerning statically admissible stress fields and kinematically admissible velocity fields.

P. R. Paslay (Houston, Tex.)

Hoh, F. C. 4391

Instabilities due to resistivity gradients in a low-pressure plasma.

Phys. Fluids **7** (1964), 956–964.

Low-frequency, quasi-electrostatic modes are studied in the paper. Macroscopic particle equations are used. Displacement currents and terms of order m/M are discarded. Finite Larmor orbit corrections are included in the equations of motion, and heat conduction is permitted via a constant parallel heat conductivity only. The stability of quasi-static configurations (resistive diffusion is ignored) of a plasma embedded in a magnetic field is examined in slab and cylindrical geometries. Gravitational forces and forces due to curvature of magnetic lines are not included. By use of the low β approximation it is shown that the stability of the system may be determined from the eigenvalues of a second-order differential equation. In limiting cases the equation reproduces modes due to resistivity gradients which have been obtained previously. Analysis of the "rippling" mode shows, within the approximations of the paper, that both finite Larmor orbits and heat conduction reduce growth rates and that finite Larmor orbits introduce overstability. However, substantial growth rates are obtained for Stellarator conditions.

Carstoiu, John 4392

Sur les ondes magnétohydrodynamiques dans un fluide en rotation uniforme.

C. R. Acad. Sci. Paris **258** (1964), 2745–2747.

The author discusses wave motions in a perfectly conducting inviscid fluid in the presence of a magnetic field. The particular application is wave motions in the ionosphere, and the novel feature is the inclusion of the rotation of the earth, Ω_0, the direction of which is taken to coincide with the magnetic field (the z-direction). The equation for the z-component of vorticity is now coupled through Ω_0 to the equation of density variation in such a manner that, for small Ω_0, Alfvén waves predominate, while for large Ω_0, acoustic waves predominate, the propagation being without attenuation in the z-direction. It is suggested that this might offer an explanation of polar noise at times of extreme aurora activity.

The general equation for density variation is obtained and a wave number surface for plane waves is deduced. The equation for the wave number surface is of the sixth degree in frequency compared with the fourth degree for $\Omega_0 = 0$. *E. G. Broadbent* (Farnborough)

Clark, Alfred, Jr. 4393

Production and dissipation of magnetic energy by differential fluid motions.

Phys. Fluids **7** (1964), 1299–1305.

The magnetohydrodynamic equations, including viscosity, are solved as an initial-value problem, under the assumption of two-dimensional stagnation flow. The x and y components of fluid velocity are assumed to be Ax and $-Ay$, respectively. The magnetic field is chosen arbitrarily as a function of y in the x direction. The stagnation plane is the xz-plane, and all quantities are independent of z. The solution is examined with attention to two effects, often previously discussed in intuitive terms, but seldom studied quantitatively: (1) the increase of magnetic field energy due to the "stretching" of magnetic field lines; and (2) enhanced Joule heating by steepening the gradients of magnetic fields. Both effects are found in the solutions, and are exhibited for special cases. The possible role of the two processes in the transfer of energy in solar flares is discussed. *D. C. Montgomery* (Utrecht)

Dunwoody, N. T. 4394

Instability of a viscous fluid of variable density in a magnetic field.

J. Fluid Mech. **20** (1964), 103–113.

Author's summary: "The instability to small two-dimensional disturbances of an electrically conducting fluid of variable density is investigated. The viscous fluid is bounded between two vertical parallel planes normal to which a magnetic field of constant intensity is applied. Significant parameters upon which the behaviour of the Rayleigh number at neutral stability depends are the Hartmann number M and the wave-number α which is associated with a periodic disturbance with periodicity in the unbounded horizontal direction. The solution may be sought by considering basic disturbances which are either symmetric or antisymmetric about the median plane parallel to the boundary planes. It is found that for a given magnetic field strength the critical Rayleigh number governing stability is associated with an antisymmetric disturbance of zero wave-number. The least stable symmetric disturbance which arises when the wave-number is zero is less easily excited. This trend is seen again in the purely hydrodynamic case ($M=0$) where, corresponding to a finite wave-number value, the more unstable mode at neutral stability is found to be an antisymmetric one. The most unstable situation occurs when both the Hartmann number and the wave number are zero. In this case the result of Wooding [same J. 7 (1960), 501–515; MR **24** #B1417] that the minimum critical Rayleigh number is zero and is associated with a symmetric disturbance is reobtained." *C. S. Gardner* (New York)

Fogagnolo, Bruna 4395

Sulle linee di discontinuità in alcuni moti magnetofluidodinamici piani, generati da un vortice puntiforme.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 613–624.

The author determines the characteristic lines for the propagation of cylindrically symmetric magnetohydrodynamic waves in a perfectly conducting fluid with a point-vortex at the central magnetic field line. He considers in detail the two special cases of constant magnetic field strength and constant Alfvén speed. The results are just what one would expect: the usual characteristic lines for a stationary fluid, which propagate radially outward with velocity $(v_s^2+v_a^2)^{1/2}$, are carried bodily into a spiral form by the assumed rotatory motion of the fluid. Here v_s denotes the speed of sound and v_a the Alfvén speed. *H. C. Kranzer* (Garden City, N.Y.)

Germeles, Apostolos E. 4396

Channel-flow of conducting fluids under an applied transverse magnetic field.

Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 165–169.

Author's summary: "The most general steady-state solution is derived for the laminar flow of an incompressible, viscous and electrically conducting fluid in a one-dimensional channel under an applied transverse magnetic field. The channel can act as an electromagnetic flowmeter or pump. The effect of the conductivity of the walls is included. The solution has two unknown constants and, by choosing them properly, it can be made to fit the solution of all two-dimensional channels whose geometry approaches in the limit that of the one-dimensional channel. This is done in detail for the two-dimensional channels with rectangular and annular cross-section."

On the rotation of a conducting fluid with a moving center. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **31** (1963), 543–549.

Proceeding from the works by Lord Rayleigh [Proc. Roy. Soc. London Ser. A **93** (1917), 148–154], Sir Napier Shaw [Meteorol. Office Geophys. Memoirs No. 12 (1918)] and others, the author studies the same problem of the rotation of a fluid, the fluid being considered compressible, however. *V. N. Constantinescu* (Bucharest)

Jeffrey, Alan 4398

Magnetoacoustic simple waves in a polytropic gas. (German summary)

Z. Angew. Math. Phys. **15** (1964), 217–227.

In magnetohydrodynamic flow small changes in the physical properties of the flow can be transmitted by magneto-acoustic simple waves. For one-dimensional flow these properties can be described by two quantities, α, β, related by a differential equation $d\alpha/d\beta=f(\alpha,\beta)$ [Friedrichs, Comm. Pure Appl. Math. **11** (1958), 333–418; MR **20** #7147]. In general, the magneto-acoustic waves have both a slow and a fast mode of propagation. By studying the integral curves in the (α,β)-plane the author shows here that no physical transition can occur between fast and slow waves. A numerical solution for one integral curve is given, together with a method for easily obtaining any other solution from it. *J. D. Jukes* (Culham)

Lykoudis, Paul S. 4399

Magnetofluidmechanic blast waves in a medium with finite electrical conductivity.

Phys. Fluids **7** (1964), 1372–1380.

The author extends the classical similarity solution of a blast wave in an ideal compressible gas to a medium with finite electrical conductivity σ and small magnetic Reynolds number. The presence of the magnetic field is found to decelerate the fluid behind the "shock wave" (a misnomer appearing in the paper as the wave does not have a finite structure) and to produce higher temperatures.

The validity and application of the solution is left obscure, for the similarity solution used is permitted to violate both Maxwell's equations and the "$\frac{3}{2}$" power law for the relation between σ and temperature. The important energy loss due to ionization is not taken into account. However, the work does represent an attempt to study a very difficult problem, even if the physics is oversimplified.

Some reciprocal relations in rotational magnetogasdynamic flow. (German summary)

Z. Angew. Math. Phys. **15** (1964), 144–154.

Les auteurs considèrent l'écoulement stationnaire, bidimensionnel d'un fluide compressible, non visqueux, non conducteur de la chaleur, parfaitement conducteur de l'électricité, soumis à un champ magnétique collinéaire à la vitesse. Après avoir rappelé l'existence d'une transformation ramenant l'étude de cet écoulement à celle de l'écoulement d'un fluide fictif non conducteur, les auteurs étudient cette analogie en étendant à la magnétodynamique des fluides une théorie déjà établie dans le cas de la dynamique des gaz [G. Power et P. Smith, J. Math. Mech. **10** (1961), 349–360; MR **23** #B1290]. Cette théorie permet alors de relier, grâce à un changement d'axes de coordonnées et à un certain nombre de relations réciproques, l'écoulement de magnétodynamique des fluides à une famille à quatre paramètres d'écoulements de dynamique des gaz, chacun d'eux correspondant à une loi d'état particulière. Les auteurs étudient alors les propriétés de ces écoulements en considérant aussi le cas d'une onde de choc.

R. Peyret (Montrouge)

Dragos, Lazar 4401

Theory of thin airfoils in magnetoaerodynamics.

AIAA J. **2** (1964), 1223–1229.

Author's summary: "This paper examines the motion of a compressible fluid with arbitrary finite electrical conductivity in the presence of a thin airfoil. At infinity, in the undisturbed stream, the magnetic fluid is assumed to be orthogonal to the direction of the fluid stream. The motion is irrotational. The velocity field and the magnetic field have an irrotational part, which coincides to that of the classical aerodynamics, and a rotational part, which is due to the field-motion interaction and which vanishes for $A \to \infty$. The general solution depends on five arbitrary functions. The boundary conditions determine the relations between these functions as well as the boundary problem for determining one of them. This one reduces to a Fredholm-type integral equation. Surface currents are not possible. The solution valid for arbitrary Mach number M coincides with the solution of the case of incompressible fluid for $M = 0$."

Skorupski, A. 4402

Alfvén waves in inhomogeneous plasmas.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 329–334.

Author's summary: "The results of Gajewski and Winterberg concerning Alfvén waves in inhomogeneous magnetic fields are generalized for inhomogeneous plasmas and magnetic fields which are not external. Particularly the case of a plane and rotational symmetry of the magnetic field in equilibrium is considered and the corresponding differential equations for the vector potential are derived. A differential equation describing the Alfvén waves was reduced to a form convenient for approximations."

Tkalič, V. S. 4403

A stationary problem in magnetohydrodynamics where two coordinates are related; collision of jets of conducting fluid. (Russian)

Izv. Akad. Nauk SSSR Otd. Tehn. Nauk Meh. i Mašinostr. **1962**, *no.* 5, 32–38.

Steady flows of conducting fluids, in which one coordinate is quasicyclic, are studied. A coordinate is defined to be quasicyclic if the magnetic field **H**, the velocity **V**, and the metric tensor g_{kl} do not depend on it, while the total pressure P and the electric potential Φ depend on it linearly. General properties of these essentially two-dimensional flows of ideal fluids are given. For fluids with dissipation, a special class of flows is constructed for which the stream function obeys the Helmholtz equation, and an energy integral is obtained for these flows.

For near-potential flows, lift and moment formulas are given, these being generalizations of the Joukowsky formulas in ordinary fluid dynamics. As a special example, the collision of two conducting fluid jets is discussed.

Vacca, Maria Teresa 4404

Sul limite di Poincaré per una massa fluida di alta conduttività elettrica uniformemente rotante in cui si genera un campo magnetico.

Boll. Un. Mat. Ital. (3) **19** (1964), 127–137.

Poincaré has shown that, for a rotating mass of self-gravitating fluid of mean density ρ_m to be in stable equilibrium, its angular speed of rotation ω must lie below the limit $\omega_0 = (2\pi f \rho_m)^{1/2}$, where f denotes the universal constant of gravitational attraction. The author shows how this limiting angular velocity is changed by the introduction of a magnetic field, assuming the fluid to be a perfect conductor. She gives an explicit general formula for the new limiting velocity in terms of ω_0 and quantities derivable from the magnetic field.

The author considers in detail the case of a magnetic field $\mathbf{H} = \mathbf{H}_0 + \mathbf{h}$, where $\mathbf{H}_0$ is a constant magnetic field directed along the axis of rotation, while $|\mathbf{h}|$ is small compared to $|\mathbf{H}_0|$ and is cylindrically symmetric: $\mathbf{h} = \mathbf{h}(r, z)$ in cylindrical coordinates (r, φ, z). She shows, first, that the quantity $-\rho^{-1}(\operatorname{curl} \mathbf{h})_\varphi$ depends on r alone, and calls it $g(r)$; here ρ denotes the local fluid density. Then the condition for stable equilibrium becomes

$$\omega^2 < \omega_0^2 + \frac{\mu|\mathbf{H}_0|}{2\tau} \int_\sigma g(r) \frac{dr}{dn}\, d\sigma,$$

where σ is the outer fluid surface, with outward unit normal $\mathbf{n}$, μ is the magnetic permeability, and τ denotes the total volume of the fluid. Thus the stability limit may be either higher or lower than the Poincaré limit, depending on the predominant sign of $g(r)$ on σ.

A note on the geometrical optics of diffraction by an interface.

Proc. Cambridge Philos. Soc. **60** (1964), 1013–1022.

It is known that solutions of the Cauchy problem for the wave equation represent disturbances obeying the laws of geometrical optics. Boundary conditions of the type representing reflection have been treated by Friedlander. Incident and reflected wavefronts exist and sometimes also a "shadow" where diffraction occurs. The diffracted wave fronts are normal to the reflecting surface, the corresponding rays travelling along the surface and leaving it tangentially. The present paper extends these results to refraction at an interface. The results are seen to be consistent with Keller's theory of diffracted rays.

The radiation field of a magnetic dipole antenna in a conical sheath.

J. Math. and Phys. **43** (1964), 199–217.

The radiation field of a magnetic point source located on the axis interior to an axially symmetric, radially infinite, infinitesimally thin conical plasma sheath is considered. Boundary conditions at the sheath are those for an impedance surface. A potential function satisfying the Helmholtz equation is established, and Green's theorem is employed to obtain an integral equation for this potential function. An iteration procedure for determining the field in inverse powers of the square of the plasma frequency is then established, and with the aid of several approximations which have the effect of restricting the applicability to small cone angles the first term in the iteration is determined. Further terms are shown to be small. The pattern and some machine computations of eigenvalues and eigenfunction values (Legendre functions) for the 10° cone are included.

It is shown that information on the radiation field in an anisotropic media may be obtained directly from the shape of the refractive index surface.

"The present expository paper has been a self-contained treatment of the theory of radiation from sources in cold

magnetoplasma media. In this review, no mention has been made of antenna impedance for anisotropic media. While this would seem to be a natural topic for this discussion, it has been deferred until a later time. One reason for this is the need to consider thermal effects and sheath phenomena, which are important near the source. Consideration resulting from the finite temperature leads to contributions from the acoustic-type waves not usually considered part of magneto-ionic theory."

Thermoelectric and thermomagnetic heat pumps.
J. Appl. Phys. **34** (1963), 3430–3441.
Simultaneous flow of heat and electricity in isotropic materials in the presence of a magnetic field is studied with the restrictions that the magnetic field is homogeneous and constant and that the current density is constant. The continuity equations for the internal energy and the heat flow, as well as for the electric charge and the current, are supplemented by the phenomenological equations of irreversible thermodynamics which express the gradient of the electrochemical potential and the heat flow in terms of the current density $\mathbf{F}$ and the temperature gradient ∇T. The coefficients in the phenomenological equations are functions of the magnetic field $\mathbf{H}$ which are approximated by retaining only linear terms in $\mathbf{H}$ in a power series expansion. The Seebeck coefficient S is considered to be a function of temperature, and the other coefficients are taken as constant. The resulting equations have been solved for the cases (1) $\mathbf{H} \neq 0$, $\mathbf{F} \| \mathbf{Q}$ or $\mathbf{F} \perp \mathbf{Q}$ and $\mathbf{F} \| \nabla T$ or $\mathbf{F} \perp \nabla T$ with $\partial S/\partial T = 0$, where Q is the reduced heat flow, (2) $\mathbf{H} = 0$, $\mathbf{F} \| \nabla T$. The geometry of the sample is a rectangular plate with $\mathbf{F}$ parallel to one of its edges and $\mathbf{H}$ orthogonal to the plate.

Author's summary: "A quantitative analysis is presented of the phenomenon of relaxation of elastic waves, due to heat transfer from the solid through radiation. A comparison is stated between the characteristic parameters of this phenomenon and those of the relaxation phenomenon due to heat conduction in the solid only."

Sparrow, E. M.; Haji-Sheikh, A.; Lundgren, T. S. 4417
The inverse problem in transient heat conduction.
Trans. ASME Ser. E. J. Appl. Mech. **31** (1964), 369–375.
A general theory is devised for determining the temperature and heat flux at the surface of a solid when the temperature at an interior location is a prescribed function of time. The theory is able to accommodate an initial temperature distribution which varies arbitrarily with position throughout the solid. Detailed analytical treatment is extended to the sphere, the plane slab, and the long cylinder, and it is additionally shown that the semi-infinite solid is a particular case of the general formulation. The accuracy of the method is demonstrated by a numerical example. In addition, a numerical calculation procedure is devised which appears to provide smooth, nonoscillatory results. *B. A. Boley* (New York)

★Methods in computational physics. 4418
Advances in research and applications. Vol. 2: Quantum mechanics.
Edited by Berni Alder, Sidney Fernbach and Manuel Rotenberg.
Academic Press, New York-London, 1963. xi + 271 *pp.* $10.00.
This is a collection of six articles dealing with computer solutions of problems in atomic and molecular physics. The

first four articles describe schemes for handling multiple integrals. The fifth article discusses a scattering calculation, while the sixth treats rather heuristically convergence rates when variational methods are used. Each article contains the physics, the numerical analysis, and the computer aspects of its respective problem. The editors indicate that these articles must be considered as progress reports, for the various computations are in the process of being evaluated and refined. The numerical analyst should find a useful supply of non-trivial computations in this book.

The six articles are (1) "The Gaussian Function in Calculations of Statistical Mechanics and Quantum Mechanics", by Isaiah Shavitt; (2) "Atomic Self-Consistent Field Calculations by the Expansion Method", by C. C. J. Roothaan and P. S. Bagus; (3) "The Evaluation of Molecular Integrals by the Zeta-Function Expansion", by M. P. Barnett; (4) "Integrals for Diatomic Molecular Calculations", by Fernando J. Corbató and Alfred C. Switendick; (5) "Nonseparable Theory of Electron-Hydrogen Scattering", by A. Temkin and D. E. Hoover; (6) "Estimating Convergence Rates of Variational Calculations", by Charles Schwartz.

Donsker, M. D. 4421

On function space integrals.

Analysis in function space, pp. 17–30. *M.I.T. Press, Cambridge, Mass.*, 1964.

Der Verfasser konstruiert zunächst eine spezielle Darstellung des δ-Funktionals, der Verallgemeinerung der Dirac'schen Deltafunktion auf den Funktionenraum, durch ein Funktional-Integral. Die gewonnene Formel wird dann zur Ableitung von Umkehrformeln für funktionale Integrationsformationen verwendet. Verfasser diskutiert ferner die Frage der Eindeutigkeit der Lösungen gewisser funktionaler Differentialgleichungen. Schließlich verwendet Verfasser die Methode der Transformationen im Funktionenraum, um den Zusammenhang zwischen funktionalen Differentialgleichungen und Randwertproblemen für partielle Differentialgleichungen zu studieren.

G. Heber (Leipzig)

Edwards, S. F. 4422

A new method of solution for quantum field theory and associated problems.

Analysis in function space, pp. 31–50. *M.I.T. Press, Cambridge, Mass.*, 1964.

Der Verfasser zeigt zunächst, daß die Grundgleichungen für drei physikalisch sehr verschiedene Gebiete auf mathematisch wesentlich die gleiche Form gebracht werden können. Und zwar handelt es sich um die Grundgleichungen der Quantenfeldtheorie, der Quantenmechanik vieler Teilchen und der homogenen Turbulenz. Dieser Umstand hat zur Folge, daß eine Lösung, welches für eines dieser Probleme konstruiert ist, auch eine Lösung der beiden zugeordneten Probleme (aus den beiden anderen Gebieten) liefert. Verfasser entwickelt eine Näherungsmethode zur Lösung des homogenen Turbulenzproblems für den Fall sehr großer nichtlinearer Terme in der Grundgleichung. Diese Methode überträgt er danach auf den Fall der Quantenfeldtheorie und der Mehrteilchen-Quantenmechanik. Dabei stößt er in ersterem Falle auf eine stark nichtlineare Integralgleichung für die Ausbreitungsfunktion. Er konstruiert eine spezielle Lösung mit einer selbst entwickelten Methode, deren mathematische Korrektheit jedoch nicht sicher ist. Diese Lösung erfüllt nicht die Lehman-Källén'sche Form einer Ausbreitungsfunktion; es gäbe in diesem Formalismus auch überhaupt keine "nackten" Teilchen und Felder mehr. Die Übertragung des Formalismus auf die Vielteilchen-Quantenmechanik enthält die Bardeen-Cooper-Schrieffer, Bogoljubow-Valatin und random-phase Näherungen, ermöglicht es aber im Prinzip, über diese Näherungen hinauszugehen.

G. Heber (Leipzig)

Gross, Leonard 4423

Classical analysis on a Hilbert space.

Analysis in function space, pp. 51–68. *M.I.T. Press, Cambridge, Mass.*, 1964.

Der Verfasser geht von der Feststellung aus, daß es keine direkte Verallgemeinerung des Lebesgue'schen Maßbegriffes für Integration über einen beliebigen Hilbertraum gibt. Verfasser bemüht sich um eine Definition dieses Maßes für eine allgemeinere Klasse von Integralen als die Wienerschen. In gewissem Sinne ist dies möglich, wenn man den Hilbertraum erweitert. Der Artikel schließt mit einigen Bemerkungen über die funktionale Fourier-Transformation.

G. Heber (Leipzig)

Kristensen, P. 4424

Tempered distributions in functional space.

Analysis in function space, pp. 69–86. *M.I.T. Press, Cambridge, Mass.*, 1964.

magnetoplasma media. In this review, no mention has been made of antenna impedance for anisotropic media. While this would seem to be a natural topic for this discussion, it has been deferred until a later time. One reason for this is the need to consider thermal effects and sheath phenomena, which are important near the source. Consideration resulting from the finite temperature leads to contributions from the acoustic-type waves not usually considered part of magneto-ionic theory."

Wait, James R. 4412
Calculated diffraction effects at VLF from a localized ionospheric depression.
Nat. Bur. Standards Tech. Note No. 208 (1964), iii+12 *pp.*
Author's summary: "Propagation of VLF radio waves in the earth-ionosphere waveguide of non-uniform width is considered. The disturbed region is permitted to be of finite extent. It is assumed that the height variations may be locally represented in terms of a propagation function $S(x, y)$ which is a function of both x and y. Using first-order scattering theory, calculations are presented for a disturbed region which is approximately rectangular in the horizontal plane."

Faugeras, Paul-Étienne 4413
Diffraction d'une onde électromagnétique plane par un cylindre de plasma inhomogène.
C. R. Acad. Sci. Paris **259** (1964), 1311–1314.
Author's summary: "On étudie la diffraction d'une onde électromagnétique par un cylindre de plasma à symétrie de révolution, dans le cas d'une onde plane à l'incidence normale et de polarisation parallèle à l'axe du cylindre. Par une méthode self-consistante, différente de l'approximation de Born, on obtient l'expression exacte du champ diffusé par le plasma, quelle que soit la distribution de la densité."

Thermoelectric and thermomagnetic heat pumps.
J. Appl. Phys. **34** (1963), 3430–3441.
Simultaneous flow of heat and electricity in isotropic materials in the presence of a magnetic field is studied with the restrictions that the magnetic field is homogeneous and constant and that the current density is constant. The continuity equations for the internal energy and the heat flow, as well as for the electric charge and the current, are supplemented by the phenomenological equations of irreversible thermodynamics which express the gradient of the electrochemical potential and the heat flow in terms of the current density **F** and the temperature gradient ∇T. The coefficients in the phenomenological equations are functions of the magnetic field **H** which are approximated by retaining only linear terms in **H** in a power series expansion. The Seebeck coefficient S is considered to be a function of temperature, and the other coefficients are taken as constant. The resulting equations have been solved for the cases (1) $\mathbf{H}\neq 0$, $\mathbf{F}\parallel\mathbf{Q}$ or $\mathbf{F}\perp\mathbf{Q}$ and $\mathbf{F}\parallel\nabla T$ or $\mathbf{F}\perp\nabla T$ with $\partial S/\partial T=0$, where Q is the reduced heat flow, (2) $\mathbf{H}=0$, $\mathbf{F}\parallel\nabla T$. The geometry of the sample is a rectangular plate with **F** parallel to one of its edges and **H** orthogonal to the plate.

Kristensen, P. 4424

Tempered distributions in functional space.

Analysis in function space, *pp*. 69–86. *M.I.T. Press, Cambridge, Mass.*, 1964.

Der Verfasser berichtet über eine Ausdehnung des Begriffes der gemäßigten Distributionen auf Funktionale. Dazu wird zuerst die Theorie der gemäßigten Distributionen etwas umformuliert. Dies wird in enger Anlehnung an Begriffsbildungen der Quantenmechanik getan. Der Übergang zu unendlich großer Zahl von Variablen wird in enger Anlehnung an die Quantenfeldtheorie vorgenommen. Die Focksche Darstellung von Hilbertraum-Vektoren spielt dabei eine besondere Rolle. Zum Schluß wird der Formalismus auf die Translations-Operatoren angewandt. *G. Heber* (Leipzig)

Nelson, Edward 4425

Schrödinger particles interacting with a quantized scalar field.

Analysis in function space, pp. 87–120. *M.I.T. Press, Cambridge, Mass.*, 1964.

Die Quantentheorie der Wechselwirkung nichtrelativistischer Teilchen mit einem skalaren Felde wird mit Hilfe funktionaler Integrale dargestellt. Dabei spielen Markoff'sche Prozesse eine wesentliche Rolle. Ultraviolett-Divergenzen werden mit Hilfe einer speziellen Methode subtrahiert; nur ein unendlicher Phasenfaktor bleibt bestehen, welcher mit einer Selbstenergie verknüpft ist. Die Existenz der verwendeten funktionalen Integrale (erstreckt über Teilchen-Bahnen) wird streng bewiesen. Es handelt sich dabei zunächst um Wienersche Integrale; der Übergang zu Feynmanschen "path-integrals" wird durch analytische Fortsetzung bzgl. des Massen-Parameters vollzogen. *G. Heber* (Leipzig)

Salam, Abdus 4426

Developments in renormalization theory.

Analysis in function space, pp. 121–128. *M.I.T. Press, Cambridge, Mass.*, 1964.

Der Verfasser betrachtet die Wechselwirkung zwischen skalaren Teilchen und Photonen sowie diejenige zwischen Teilchen mit Spin 1 und Photonen. Sein Ausgangspunkt sind die bekannten Integralgleichungen für die Greenschen Funktionen der zugeordneten Felder. Außerdem spielt die Ward'sche Identität eine wesentliche Rolle. Der Verfasser schlägt eine spezielle, nicht-störungstheoretische Methode zur Lösung dieser Gleichungen vor, in welcher auch die gewöhnlichen Dispersionsrelationen verwendet werden. Es scheint sich zu ergeben, daß auch die Wechselwirkung zwischen Vektormesonen und Photonen bei Verwendung der vorgeschlagenen Näherung renormierbar wird, jedoch nur für spezielle Werte der Masse der Mesonen und der Kopplungskonstante. *G. Heber* (Leipzig)

Segal, Irving 4427

Quantum fields and analysis in the solution manifolds of differential equations.

Analysis in function space, pp. 129–153. *M.I.T. Press, Cambridge, Mass.*, 1964.

Der Verfasser befaßt sich recht allgemein mit dem Zusammenhang zwischen partiellen Differentialgleichungen, wie sie in der Quantenfeldtheorie auftreten, und Methoden der Analysis im Funktionenraume. Dabei beschränkt er sich wesentlich auf Bosonen-Felder, über Fermionen-Felder findet man am Schluß der Einleitung einige Bemerkungen. Zuerst betrachtet Verfasser "allgemeine lineare Felder", wobei er u.a. auf verschiedene Aspekte des Begriffes der Kausalität und Lokalität eingeht. Danach wendet er sich der wohl einfachsten Klasse nichtlinearer Felder zu, welche durch die Gleichung $(\Box - m^2)\varphi = g^2\varphi^p$ gekennzeichnet ist. Hier wird insbesondere der Fall $p = 3$ betrachtet. Der Verfasser schlägt vor, diese Gleichung leicht abzuändern, und zwar so, daß die neue Gleichung mathematisch wohldefiniert ist (die Ausgangsgleichung hat nicht diese Eigenschaft). *G. Heber* (Leipzig)

Siegert, A. J. F. 4428

Applications of function space integrals to problems in equilibrium statistical mechanics.

Analysis in function space, pp. 154–163. *M.I.T. Press, Cambridge, Mass.*, 1964.

Als Beispiel zur Verwendung der funktionalen Integration zur Berechnung einer Zustandssumme innerhalb der statistischen Mechanik wird das Ising-Modell behandelt. In einer bestimmten Näherung bzgl. des Integranden erhält man dabei die bekannte Molekularfeld-Näherung. Man kann aber auch die nächsten Korrekturen zu dieser Näherung berechnen. Möglichkeiten und Schwierigkeiten bei der Ausführung der hierzu erforderlichen Integrationen werden besprochen. *G. Heber* (Leipzig)

Edwards, S. F. 4429

Applications of functional integration to nonrelativistic physical problems.

Analysis in function space, pp. 167–178. *M.I.T. Press, Cambridge, Mass.*, 1964.

Der Verfasser geht davon aus, daß viele auf irgendeine Weise lösbaren Probleme der nichtrelativistischen theoretischen Physik auch durch Funktionalintegrale darstellbar sind. Oft ist es so, daß man diese Funktionalintegrale mit den heute bekannten Methoden nicht ausrechnen kann, ja daß noch nicht einmal Existenzbeweise für alle in der Physik auftretenden Integrale geführt sind. Da aber die Lösung anderweitig bereits bekannt ist, kann man indirekt auf Existenz und Eigenschaften vieler Funktional-Integrale schließen. Dies wird im vorliegenden Aufsatz für eine Reihe von konkreten Beispielen getan. Hierbei ergibt sich u.a. der sehr wichtige Schluß, daß ein Funktionalintegral, dessen Integrand von einem Parameter stetig abhängt, durchaus keine stetige Funktion dieses Parameters sein muß. *G. Heber* (Leipzig)

Kastler, D. 4430

A C^*-algebra approach to field theory.

Analysis in function space, pp. 179–191. *M.I.T. Press, Cambridge, Mass.*, 1964.

Remarks on the mathematical structure of quantum field theory.

Analysis in function space, pp. 192–196. *M.I.T. Press, Cambridge, Mass.*, 1964.

Kurze Diskussion der mathematisch strengen Fassung der

grundlegenden Axiome (Lokalität, Lorentz-Invarianz und Stabilität) der Quantenfeldtheorie und einiger ihrer Konsequenzen. *G. Heber* (Leipzig)

Symanzik, K. 4432

Application of functional integrals to Euclidean quantum field theory.

Analysis in function space, pp. 197–206. *M.I.T. Press, Cambridge, Mass.*, 1964.

Der Verfasser zeigt, daß nach Übergang von einem 4-dimensionalen Minkowskischen zu einem 4-dimensionalen Euklidischen Raum und nach Einführung eines endlichen Volumens und eines Spektrums von Hilfsmassen die Funktional-Integral für die Greenschen Funktionen eines nichtlinearen, skalaren Feldes existieren. Er gibt auch Abschätzungen für diese Integrale an, kann sie aber nicht explizit ausrechnen. *G. Heber* (Leipzig)

Schwartz, Melvin 4433

Lagrangian and Hamiltonian formalisms with supplementary conditions.

J. Mathematical Phys. **5** (1964), 903–907.

A physical system with supplementary conditions can usually be treated by the Lagrangian multiplier method in classical physics. It is found, however, that the formulation of its quantum version is not as straightforward as it looks. A straightforward quantum mechanical treatment of such a system is to eliminate supplementary conditions by reducing the number of variables. However, this method sacrifies the symmetry among all the original variables. The reviewer formulated a Hamiltonian formalism when there is one supplementary condition, under the rule of our game, to construct a Hamiltonian formalism without discriminating any of the variables in such a manner that it can be quantized [the reviewer, Phys. Lett. **1** (1962), 278–279; MR **25** #4869]. The present paper deals with a system in which there are N independent supplementary conditions on the differentials of n coordinates. The relation of this formalism to the Lagrangian multiplier method is also discussed. Three examples are given; (i) particles on a sphere, (ii) vacuum electrodynamics in configuration space, and (iii) the same in momentum space. Compare with the similar approach by Skinner [Canad. J. Phys. **34** (1956), 901–913; MR **18**, 443]. *Y. Takahashi* (Dublin)

Kinoshita, T.; Loeffel, J. J.; Martin, A. 4434

New upper bound for the high-energy scattering amplitude at fixed angle.

Phys. Rev. Lett. **10** (1963), 460–462; *erratum, ibid.* **11** (1963), 138.

Froissart [Phys. Rev. (2) **123** (1961), 1053–1057] showed that (for equal mass scalar particles) the Mandelstam cut plane analyticity in $\cos\theta$, together with unitarity, provides the following upper bounds at high energy on the scattering amplitude:

$$(1)\qquad |f(s, \cos\theta)| < C_1 s(\log s)^2 \quad \text{for } \theta = 0 \text{ or } \pi,$$

$$(2)\qquad |f(s, \cos\theta)| < C_2 s^{3/4}(\log s)^{3/2} \quad \text{for } \theta \neq 0 \text{ or } \pi.$$

The reviewer and Low [ibid. (2) **124** (1961), 2047–2048; MR **24** #B1917] showed that the less restrictive analyticity in that Lehmann ellipse which follows from local quantum field theory, together with unitarity, leads to weaker high-energy bounds, and also pointed out that analyticity in the bigger Lehmann ellipse which touches the Mandelstam cuts leads to Froissart's bounds (1) and (2). This last result was later found independently by Martin [ibid. (2) **129** (1963), 1432–1436; MR **27** #2291]. In the present article, the authors assume analyticity in a domain D_s which includes the latter Lehmann ellipse and remains a fixed finite distance away from it, except near $\cos\theta = \pm 1$, where the Mandelstam cuts enter, for all values of s. From this larger domain of analyticity, together with unitarity, the authors find the high energy bound

$$(3)\qquad |f(s, \cos\theta)| < C' \frac{(\log s)^{3/2}}{\sin^2\theta},$$

uniformly in θ, which improves (2) above.
O. W. Greenberg (College Park, Md.)

Azimov, S. A.; Arušanov, G. G. 4435

Some formulae for the elastic scattering of particles of higher energy. (Russian. Uzbek summary)

Izv. Akad. Nauk UzSSR Ser. Fiz.-Mat. Nauk **1964**, *no.* 2, 69–76.

Considering the elastic scattering of spin-zero particles at high energies, the authors obtain some relations between scattering amplitudes or cross-sections by replacing the formulae

$$a_{l+1} - a_l = \frac{da_l}{dl}, \qquad \sum_{l=l_0}^{\infty} \to \int_{l_0}^{\infty}$$

by the exact series

$$a_{l+1} - a_l = \sum_{n=1}^{\infty} \frac{1}{n!} a_l^{(n)},$$

$$\sum_{l=l_0}^{L} f(l) = \int_{l_0}^{L} f(l)\,dl + \tfrac{1}{2}[f(l_0) + f(L)] + \sum_{k=1}^{n} \frac{B_{2k}}{(2k)!}[f^{(2k-1)}(L) - f^{(2k-1)}(l_0)] + R_n.$$

In particular, they consider the backward scattering and the scattering in the neighbourhood of 180°, the scattering at 90° and in the neighbourhood of 90°, and finally the scattering at angles not equal to 0 or π. They obtain some interesting results, e.g., that the cross-section $\sigma(\vartheta)$ for scattering at fixed non-zero angles must obey the inequality $\sigma(\vartheta) \lesssim 1/k^2$; this is a stronger statement than that obtained by T. Kinoshita, J. Loeffel, and A. Martin [see #4434 above] on the basis of analytical properties of the scattering amplitude. *M. Blažek* (Bratislava)

Bingel, Werner A. 4436

The behaviour of the first-order density matrix at the Coulomb singularities of the Schrödinger equation.

Z. Naturforsch. **18a** (1963), 1249–1253.

Author's summary: "The cusp conditions of Kato for a spinless n-electron wave function at the Coulomb singularities of the Schrödinger equation are used to derive corresponding conditions for the first-order density matrix. These results are applied to the united-atom expansion of the electronic energy of polyatomic molecules resulting in an exact relation between the coefficients of

the quadratic and cubic terms in this expansion. Finally it is shown how the cusp condition for the first-order density matrix is modified if the wave function includes electron spin in a proper way." *A. J. Coleman* (Kingston, Ont.)

Calogero, F. 4437

A novel approach to elementary scattering theory. (Italian summary)

Nuovo Cimento (10) **27** (1963), 261–302.

The conventional method to compute phase shifts is based on the regular solution of a second-order wave equation. On the other hand, in the method proposed a function $\delta(l, k; r)$ is introduced which satisfies a first-order nonlinear differential equation, and whose asymptotic value gives directly the value of the phase shifts. The phase function introduced, $\delta(l, k; r')$, has a very simple physical meaning: it is the phase shift produced by the potential $V(r)\theta(r'-r)$, where $\theta(r)$ is the step function, i.e., the phase shift that the potential $V(r)$ produces after it has been amputated of its part extending beyond r'. Also a closed expression for the amplitude of the Jost function, whose absolute value squared measures the effect of the potential on the wave function at the origin, is given in terms of this phase function.

For a numerical computation the method introduced is far superior to the conventional one. Also because of its simplicity and transparency, it allows one to derive general theorems on phase shifts in a much simpler way than would be possible through the standard method. The s-wave phase shift is worked out numerically for an attractive square-well. In particular, the validity of Levinson's theorem in the limit of zero energy is nicely demonstrated. Upper and lower bounds on the phase shifts and on their derivatives with respect to linear and angular momentum are established. For small phase shifts, e.g., in the case of high energy, it is possible to linearize the appropriate differential equation, and approximate expressions for the phase shifts are obtained. The zeroth approximation coincides with the first Born approximation and a less drastic approximation yields the so-called improved Born approximation. The latter turns out to coincide with the first term of an expansion recently derived by the reviewer and S. Tani [Phys. Rev. (2) **131** (1963), 396–406; MR **28** #3676]. Next, it is shown how, through the use of trial functions, approximate values of the phase shifts may be obtained. Under the assumption that the potential never changes sign and that the phase shift is smaller in magnitude than $\pi/2$, a formula is given which appears particularly suited for the evaluation of the tangent of the phase shift by means of trial functions, and which has the important advantage over the usual variational method that it provides information on the sign of the error involved. Finally, an interesting method is given for the determination of the energies of bound states, and two examples are briefly discussed.

S. Rosendorff (Haifa)

Calogero, F. 4438

A variational principle for scattering phase shifts. (Italian summary)

Nuovo Cimento (10) **27** (1963), 947–951.

A variational principle for the tangent of the phase shift and for the phase shift itself is established. The two restrictions (the potential never changes sign and the phase shift is smaller than $\pi/2$) required in the preceding paper [#4437] have been lifted; however, the information on the sign of the error is lost. *S. Rosendorff* (Haifa)

Calogero, F. 4439

The scattering of a Dirac particle on a central scalar potential. (Italian summary)

Nuovo Cimento (10) **27** (1963), 1007–1016.

The new approach to the theory of potential scattering developed in the two previous papers [#4437, #4438] for Schrödinger particles is extended to Dirac particles. This is achieved without transforming the Dirac problem into a Schrödinger problem. As a result, the equations that are obtained are simple and have a very direct physical interpretation. Variational formulas for the tangent of the phase shift and the phase shift itself are obtained, and approximate formulas are given. A theorem due to Parzen [Phys. Rev. (2) **80** (1950), 261–268; MR **12**, 571] concerning the asymptotic behavior of the phase shifts at large energies is easily proved. *S. Rosendorff* (Haifa)

Chan, H. H.; Razavy, M. 4440

Plane-wave approximation for the scattering amplitude.

Canad. J. Phys. **42** (1964), 1017–1029.

In potential scattering the first Born approximation is unsatisfactory for an approximate determination of the low-energy scattering parameters (s-wave effective range and scattering length) because it is non-unitary. It is possible to formulate a second Born approximation which is unitary in a number of different ways, depending on the exact equation to which approximate solutions are being sought. In this paper four such approximations are discussed and compared with the exact solution for a number of cases where this is readily obtainable. Although, of course, all of the approximations agree in the limit of vanishingly weak potentials, they differ considerably for stronger potentials. An approximation based on a variational technique due to Schwinger is consistently superior. *J. M. Charap* (London)

Fikioris, J. G.; Waterman, P. C. 4441

Multiple scattering of waves. II. "Hole corrections" in the scalar case.

J. Mathematical Phys. **5** (1964), 1413–1420.

Part I was under the authorship of Waterman and Truell [same J. **2** (1961), 512–537; MR **23** #B788]. The present paper takes up scattering due to a random distribution of spheres in the region $z \geq 0$, starting with the equation

$$(*)\quad \langle\psi^E(\mathbf{r}|\mathbf{r}_1)\rangle = \psi^{\text{inc}}(\mathbf{r}) + \int_\tau n(\mathbf{r}'|\mathbf{r}_1)T(\mathbf{r}')\langle\psi^E(\mathbf{r}|\mathbf{r}')\rangle\,d\tau'$$

for the configurational average of the exciting field $\psi^E(\mathbf{r}|\mathbf{r}_1)$ at $\mathbf{r}=(x, y, z)$ acting on a scatterer at $\mathbf{r}_1$; $n(\mathbf{r}|\mathbf{r}_1)$ is the conditional density of scatterers, which in the present case is taken to be n_0 for $|\mathbf{r}'-\mathbf{r}|>b$, $z'>0$, $z>0$, and 0 otherwise; $T(\mathbf{r}')$ is an operator, which when operating on $\langle\psi^E(\mathbf{r}|\mathbf{r}_1)\rangle$, yields the field scattered by the sphere at $\mathbf{r}_1$ due to the exciting field; $b \geq 2a$ is the least distance between centers of neighboring spheres, each of radius a. From the fact that the fields satisfy the Helmholtz

equation in k and $\mathbf{r}$, one obtains expansions that can be inserted into (*) and arrives at an infinite set of integral equations for the unknown coefficients in the expansion of $\langle\psi^{E}(\mathbf{r}|\mathbf{r}_1)\rangle$. This set is reduced to an infinite system of linear algebraic equations by means of certain heuristic assumptions; these give to the resulting solution the status of a zeroth order approximation in an iteration process. Successive approximations after the first become very complicated, and convergence has not been investigated.

In the low-frequency limit, the zero-order solution agrees with known results in the acoustic case. As a consequence of the deductions from this analysis, it is found to be necessary to qualify certain of the conclusions in Part I. *R. N. Goss* (San Diego, Calif.)

Gluckstern, R. L.; Lin, Shin-R 4442

Relativistic Coulomb scattering of electrons.

J. Mathematical Phys. **5** (1964), 1594–1602.

Authors' summary: "A simple and useful relation between the Coulomb amplitudes F and G (in Mott's notation) is derived and F and G are evaluated analytically up to α^4 terms for arbitrary $q=\alpha/\beta$. These results are valid for all angles, but are particularly useful at small angles. The general analytic behavior of F and G in the variable $x=\sin\frac{1}{2}\theta$ is discussed. The method is applicable to higher-order terms (α^6 and up). A double integral representation of F is also derived by using the Sommerfeld-Watson transformation. This integral representation exhibits the dependence on α, q, and θ separately."

Jordan, Thomas F. 4443

Lorentz invariant multichannel scattering formalism.

J. Mathematical Phys. **5** (1964), 1345–1360.

Author's summary: "A manifestly Lorentz invariant Hamiltonian formalism for multichannel scattering and production processes is developed by making two simple and natural extensions of the ordinary quantum mechanical formalism. The first is the asymptotic covariance postulate of Fong and Sucher [same J. **5** (1964), 456–470; MR **28** #5703] which is essentially a necessary and sufficient condition for Lorentz invariance of the scattering amplitudes. The second is a Lorentz invariant extension of the asymptotic condition. It is shown that the latter is in fact no extension at all in a case where the total momentum operators of the asymptotic (unperturbed) systems are the same as the total momentum operators of the interacting system. In such a case the ordinary multichannel scattering formalism is completely Lorentz invariant whenever asymptotic covariance is satisfied."

Pais, A.; Wu, Tai Tsun 4445

Scattering formalism for singular potential theory.

Phys. Rev. (2) **134** (1964), B1303–B1307.

The problem of determining the physically interesting quantities in the frame of static singular potentials is considered here. It is shown that the scattering amplitude in these cases exists as the limit of the ratio of two functions, neither of which, however, has a definite limit. For illustrative purposes some examples are given considering the various possibilities. A similar proposal for defining the S-matrix elements was earlier suggested by N. Limić [Nuovo Cimento (10) **26** (1962), 581–596; MR **26** #4662]. Alternative and different approaches have also been considered by several authors [N. N. Khuri and A. Pais, Rev. Modern Phys. **36** (1964), 590–595; MR **29** #973; G. Tiktopoulos and S. B. Treiman, Phys. Rev. (2) **134** (1964), B844–B847; MR **29** #3170; A. Pais and T. T. Wu, J. Mathematical Phys. **5** (1964), 799–804; MR **29** #974] by using cut-off and peratization-like procedures, and by H. Cornille and E. Predazzi [CERN preprint 9125/Th. 441] by connecting two limiting procedures.

Perturbation des niveaux de résonance d'un potentiel central. (English summary)

Bull. Soc. Roy. Sci. Liège **33** (1964), 324–336.

Author's summary: "The general solution of the perturbation problem of resonant states is given to the first order for a spherically symmetric potential. In the particular case of the perturbation of a critical potential, higher orders are given and as illustrative example, a square-well potential is finally considered."

Lütken, Hans; Winther, Aage 4448

Coulomb excitation in deformed nuclei.

Mat.-Fys. Skr. Danske Vid. Selsk. **2**, no. 6, 32 pp. (1964).

Authors' summary: "In multiple Coulomb excitations of deformed nuclei one may observe also a weaker excitation of rotational bands which are associated with states of different intrinsic structure. In the present work, the excitation amplitudes of such states have been computed in the approximation where one neglects the energy differences between the states of a rotational band. For the case of dipole, quadrupole and octupole excitations, the results are given in the form of tables. They show that the relative population of the states within a band

depends strongly on the spin and K quantum numbers, as well as on admixtures in the wave function of components from the ground-state band. A detailed investigation of the dependence of the cross-section on scattering angles is presented. One finds here appreciable deviations from the so-called $\chi(\vartheta)$-approximation, especially concerning the excitation of the unnatural parity states."

Dirac, P. A. M. 4449

Hamiltonian methods and quantum mechanics. (Larmor Lecture)

Proc. Roy. Irish Acad. Sect. A **63**, 49–59 (1964).

The author surveys the Hamiltonian form of dynamics starting with classical nonrelativistic mechanics and working up through relativity and quantization to quantum field theory and also to general relativity. In relativistic theories, the role of the Hamiltonian is played by the ten generators of the inhomogeneous Lorentz group, and the consistency conditions on these "Hamiltonians" is nothing else than the commutation (or Poisson bracket) relations of the Lie algebra of the generators of this group. The lecture concludes with some remarks on difficulties encountered in nonlocal theories. *R. Ingraham* (University Park, N.M.)

Grossmann, Alexander 4450

Nested Hilbert spaces in quantum mechanics. I.

J. Mathematical Phys. **5** (1964), 1025–1037.

Let A be a self-adjoint operator defined on a Hilbert space H. The resolvent $R(z)=(z-A)^{-1}$ of A is then a bounded normal operator-valued function of z, analytic for all values of z in the upper half-plane, but singular on the spectrum of A. It may happen, however, that for certain vectors f in H, the function $(R(z)f,f)$ remains bounded as z approaches the spectrum of A, and even admits an analytic continuation across the spectrum into the lower half-plane. In many physical applications it is of considerable interest to locate and describe such vectors in terms of the physically relevant available data. For an extended discussion of this situation, see the survey article by C. L. Dolph [Bull. Amer. Math. Soc. **67** (1961), 1–69; MR **25** #5612].

The author's contribution to the problem boils down to the observation that it is sometimes possible to renorm the Hilbert space in such a way that the new norm is finite only on vectors of the required form. This means only that there sometimes exists a bounded positive operator P with zero null space, such that $PR(z)P$ remains bounded as z approaches the spectrum of A and even admits an analytic continuation across this spectrum. He gives several concrete examples of operators A for which there does exist an operator P which "removes" the continuous singularities of $R(z)$ (e.g., $H=\mathscr{L}^2(E_3)$, $A=-\nabla^2$, and P is multiplication by a bounded square-integrable function $V(x)$), and proves that the isolated singularities of $R(z)$ cannot be removed by any choice of P.

The analytic continuation of $R(z)$ so obtained, however, depends on the choice of P. The problem of providing a prescription for making this choice in particular cases remains unsolved. *R. T. Prosser* (Lexington, Mass.)

Bailey, Paul B. 4451

Exact quantization rules for the one-dimensional Schrödinger equation with turning points.

J. Mathematical Phys. **5** (1964), 1293–1297.

Author's summary: "It is pointed out that, for a number of problems, exact quantization rules exist which closely resemble those of Bohr-Wilson-Sommerfeld. In some cases it is shown how these rules may be derived mathematically from the Schrödinger equation."

I. Bialynicki-Birula (Warsaw)

Spector, Richard M. 4452

Exact solution of the Schrödinger equation for inverse fourth-power potential.

J. Mathematical Phys. **5** (1964), 1185–1189.

The problem of constructing the various physically relevant quantities for the $1/r^4$ potential is considered. The Schrödinger equation is explicitly solved in terms of Mathieu functions (for both the cases of attractive and repulsive potentials) in the nonzero energy case. The S matrix is also briefly discussed in the repulsive case. The advantage of this approach lies in the fact that it reduces the problem to the use of mathematically well-known functions. It should, however, be noticed that the method cannot usually be extended to more general kinds of singular interactions because the $1/r^4$ case is the most singular one for which the Schrödinger equation can be solved exactly in terms of known functions in the non-zero energy limit. This is due to the appearance of more and more essential singularities as it increases the kind of singularity of the interactions. Furthermore, the $1/r^4$ case is very symmetrical in the sense that the solutions of the Schrödinger equation have in this case the same kind of (essential) singularity both at infinity and at the origin. This can be most simply understood by making the change of variable $r=1/x$ which shows that the energy and the potential term exchange their role. If one wants to calculate the physical quantities in the non-zero energy limit for more general classes of singular interactions, other approaches need to be considered. This problem has been recently investigated and solved by several authors and with different techniques. *E. Predazzi* (Chicago, Ill.)

Segal, Irving 4453

Interprétation et solution d'équations non linéaires quantifiées.

C. R. Acad. Sci. Paris **259** (1964), 301–303.

The author rewrites a typical non-linear local field equation, such as $\Box\phi=m^2\phi+g\phi^3$ together with the canonical commutation rules, in terms of commutator bracket expressions for the 3-dimensionally smeared fields $\Phi(f,t)=\int\phi(x,t)f(x)\,d^3x$ and their first and second time derivatives. He claims that the resulting set of multiple commutator brackets is a well-defined set of relations equivalent to the original poorly defined local field equation. He also claims to give an explicit solution of these commutator bracket equations. {To the reviewer at least some of the divergence difficulties arising in the local field equation must persist in the commutator bracket equations. This is because the wave function renormalisation constants would seem to enter into the commutator bracket equations for renormalised fields.}

Čistjakov, A. L. 4454

The scattering operator in the second quantization space. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 66–69.

It is proved that there exists an elastic part of the scattering operator for the energy operators of quantum mechanical systems with a variable number of particles. Systems with a variable number of particles are described by means of second quantization methods. The author also treats the Bose- and the Fermi-fields separately.

The existence of the wave operators, by analogy with the usual quantum mechanics [J. M. Jauch and I. I. Zinnes, Nuovo Cimento (10) **11** (1959), 553–567; MR **21** #6223], is asserted on the basis of the fact that the curves described in Hilbert space by the vectors $U_0(t)\phi$ when the time t varies from 0 to $\pm\infty$ are finite. One has $U_0(t)=\exp(iHt)\exp(-iH_0t)$, where H (and H_0) is the Hamiltonian of the interacting (and non-interacting) system and ϕ is the state vector from which one forms the Hilbert space considered. *M. Blažek* (Bratislava)

On algebraic problems in the theory of complex angular momentum.

Nuclear Phys. **47** (1963), 124–128.

Author's summary: "A method is given for reducing 'algebraic' operations on complex angular momenta (addition, recoupling, etc.) to ordinary angular momentum algebra, by expanding the matrix elements $\mathscr{D}^j_{mm'}(R)$ for complex j into an orthogonal series. The generalization of vector coupling coefficients and their sum rule for complex total angular momenta are treated as examples."

Efimov, G. V. 4456

On local quantum field theory without ultra-violet divergences. Third order. (Italian summary)

Nuovo Cimento (10) **32** (1964), 1046–1058.

This article continues the investigation of a self-coupled scalar field theory, where the coupling term grows less rapidly for large field strengths than the free field term. In an earlier investigation [Ž. Èksper. Teoret. Fiz. **44** (1963), 2107–2117; MR **28** #2805] it was shown that such couplings, if also obeying some additional conditions, will not give rise to ultraviolet divergences in second-order perturbation theory. In this article the third order in perturbation theory is investigated, and it is shown by the same methods that under the same conditions no ultraviolet divergences appear, and unitarity is satisfied. *W. M. Frank* (Rehovot)

Flamm, D.; Freund, P. G. O. 4457

Requirements of self-consistency in quantum field theories. (Italian summary)

Nuovo Cimento (10) **32** (1964), 486–492.

This interesting paper analyzes the self-consistency of the known renormalizable quantum field theories. In this context self-consistency consists in the finiteness of solutions of the Dyson-Schwinger system of integral equations for propagators and vertex functions, that is, finite values for all renormalization constants, along the lines of Baker and Johnson [K. Johnson, M. Baker and R. S. Willey, Phys. Rev. Lett. **11** (1963), 518–520; MR **29** #3157]. The answer is that none of the known renormalizable theories, other than electrodynamics of spin $\frac{1}{2}$ particles, is self-consistent. *V. de Alfaro* (Princeton, N.J.)

Frantz, L. M. 4458

High-intensity quantum electrodynamics. I. Intensity dependences for Feynman diagrams.

Phys. Rev. (2) **134** (1964), B1419–B1429.

Author's summary: "The prescriptions for evaluating Feynman diagrams in quantum electrodynamics are extended to the regime of incident photon beams having nonzero intensity. This is done both for the time-dependent formulation of the S-matrix perturbation theory, and for the stationary-state Brillouin-Wigner perturbation development. The results are applicable to a theory of any boson field, as they depend only on the Bose-Einstein commutation properties of the field operators; no restrictions are made on the nature of the interaction Hamiltonian. It is shown that, as far as radiative corrections are concerned, the presence of the incident beam is to be ignored; it is to be manifested by a weighting factor which depends on the count of only external photon lines connected to the scatterer line. The distribution of the incident photons over modes of the radiation field is completely arbitrary, and the results are valid to all orders in the perturbation theory." *F. Calogero* (Rome)

On some topological properties of Feynman graphs and their application to formulas related to the Feynman amplitudes.

J. Mathematical Phys. **5** (1964), 1255–1260.

The topological notion of tree set is introduced. It is then used to prove two theorems about Feynman integrals in parametric form. The first theorem proves the equivalence of the usual integral representation to that used by Symanzik. The second is the rederivation of a result of Nakanishi. *F. R. Halpern* (La Jolla, Calif.)

Hepp, Klaus 4460

Lorentz invariant analytic S-matrix amplitudes.

Helv. Phys. Acta **37** (1964), 55–73.

As a continuation of a previous work [same Acta **36** (1963), 355–375; MR **27** #5504], the author investigates a decomposition of analytic relativistic S-matrix elements $T_\alpha(p)$ into a sum of Lorentz covariant polynomials $Q_\alpha{}^\lambda(p)$ with invariant analytic amplitudes $T_\lambda(p)$ as coefficients. Instead of a domain in C^{4n} in the previous work, the author is now concerned with a domain (R,π,M) over the mass shell $M=\{p;\sum p_i=0, p_i{}^2=m_i{}^2\}$ of n complex momenta $p=\{p_i\}$ with a locally topological mapping π from R into M (in short, a non-schlicht domain with the mass shell restriction). The masses m_i are assumed positive.

$I_{(+)}$ denotes the mapping from p to $L_{(+)}(C)$ invariants of p. ($I_{(+)}$ stands for "I or I_+" and the same for $L_{(+)}(C)$.) A domain (R,π,M) is $I_{(+)}$ saturated if there exists a schlicht covering $\{V_\mu\}$ of R such that $I_{(+)}{}^{-1}I_{(+)}\pi(V_\mu)=\pi(V_\mu)$. The largest $I_{(+)}$ saturated subdomain of (R,π,M) is its $I_{(+)}$ saturated kernel $(R^{\kappa+},\pi,M)$.

It is proved (Theorem 1) that $I_{(+)}M$ is a normal algebraic set and that every $L_{(+)}(C)$ invariant amplitude $T(p)$, holomorphic on an $L_{(+)}(C)$ invariant domain, can be

written as $T = \hat{T}_{(+)} I_{(+)}$ on $(R^{n(+)}, \pi, M)$ with a unique holomorphic function $\hat{T}_{(+)}$ of $L_{(+)}(C)$ invariants. Further, it is proved (Theorem 2) that every covariant $T_\alpha(p)$, holomorphic in a common domain (R, π, M), can be decomposed (globally) as $T_\alpha = \sum_\lambda T_\lambda Q_\alpha^{\ \lambda}$ with T_λ holomorphic in a given holomorphically convex $L_{(+)}(C)$ invariant subdomain $(R^{H(+)}, \pi, M)$ of $(R^{n(+)}, \pi, M)$. The decomposition is unique for $n \leqq 4$.

The author investigates the restrictions due to Π-, T- and C-invariance and due to the Pauli principle. The results are exemplified for the "spin $\frac{1}{2}$, spin $\frac{1}{2}$" scattering amplitudes in Appendix B. *H. Araki* (Kyoto)

Jin, Y. S.; Martin, A. 4462

Remarks on the polynomial boundedness in the Mandelstam representation.

J. Mathematical Phys. 5 (1964), 1406–1412.

Authors' summary: "The Mandelstam representation is a statement about the region of analyticity and asymptotic behavior (polynomial boundedness) of a scattering amplitude. In virtue of the unitarity condition, however, these two are not completely independent. Some physical consequences, e.g., uniqueness, polynomial boundedness of the total cross-section, etc., which have been already derived from the Mandelstam representation, are shown to be preserved, even if the polynomial boundedness is replaced by a somewhat weaker assumption. By making use of unitarity, analyticity and crossing symmetry, the following type of scattering amplitude $F = E + M$, where E is an entire function in both variables s and t, while M denotes a Mandelstam-type function with finite number of subtractions, is shown to be ruled out. Similarly, $F = EM$ is also ruled out if one imposes the additional restriction that E should increase less fast than an exponential in one variable while the other is finite."

Relativistic model field theory.

Phys. Rev. (2) **134** (1964), B605–B611.

Author's summary: "A relativistic generalization of the Lee model is constructed and solved in the first sector. The solubility is achieved with an indefinite metric and a redefinition of antiparticle operators, which amounts to a selection rule prohibiting pair creation. The renormalization of the V-particle results in three dressed states, one of which is a ghost. The properties of these states and their dependence on cutoff and coupling strength are discussed. The effects of various modifications of the interaction are analyzed. Thirdly, the N-θ problem is solved exactly." *W. M. Frank* (Rehovot)

Nakanishi, Noboru 4465

Fundamental properties of perturbation-theoretical integral representations. III.

J. Mathematical Phys. 5 (1964), 1458–1473.

Part II appeared in same J. **4** (1963), 1385–1392 [MR **27** #6524]. In this continuation of the author's investigation of perturbation-form integral representations, their asymptotic behavior is discussed. A number of theorems are proven for the two-variable representation, upon imposing certain strong restrictions on the asymptotic behavior and singularities of the weight function. A heuristic discussion of more general cases is also given, relating asymptotic increase of the amplitude in certain directions to the singularities of the weight function for unsubtracted representations, and giving some conjectures in the subtracted case. *S. Deser* (Waltham, Mass.)

Petrina, D. Ja. 4466

On the principle of maximal analyticity over the complex orbital moment. (Russian)

Ukrain. Mat. Ž. **16** (1964), 502–512.

The properties of the partial scattering amplitude in the (total) orbital momentum complex plane, both in the nonrelativistic quantum mechanics and in the quantum field theory, were studied by various authors. In this paper the investigation is performed by means of the regularization methods developed for the diverging integrals of the form $\int_0^1 x^\lambda \varphi(x)\, dx$ (Re $\lambda < -1$, $\varphi(x)$ regular for $x \to 0$) [in accordance with the work of I. M. Gel'fand and G. E. Šilov, *Generalized functions* (Russian), Part 1, Fizmatgiz, Moscow, 1958; MR **20** #4182].

For instance, in the nonrelativistic scattering when one deals with the Schrödinger equation

$$\psi''(z) + k^2\psi(z) - \frac{l(l+1)}{z^2}\psi(z) - v(z)\psi(z) = 0$$

and with the Yukawa potential $v(z) = [\exp(-\mu z)]/z$, one

uses the following analytic continuation in the regular solution obtained by means of the iteration procedure

$$\frac{1}{z^{\lambda-1/2}}\int_0^z z_1^{2\lambda+1}[v(z_1)-k^2]\,dz_1 =$$

$$\frac{1}{z^{\lambda-1/2}}\left\{\int_0^z z_1^{2\lambda}\left[V(z_1)-V(0)-\cdots-\frac{z_1^m}{m!}V^{(m)}(0)\right]dz_1\right.$$

$$\left.+\frac{z^{2\lambda+1}}{2\lambda+1}V(0)+\cdots+\frac{z^{2\lambda+m+1}}{(2\lambda+m+1)m!}V^{(m)}(0)\right\},$$

$$\lambda = l+\tfrac{1}{2},$$

where $V(z)=z[v(z)-k^2]$ for $-1<m+1+2\,\mathrm{Re}\,\lambda$ (m is arbitrary). The author uses a similar continuation for the relativistic case (Mandelstam representation).

Rayski, Jerzy 4468

Resonant states of nucleon and bilocal field theory.

Helv. Phys. Acta **36** (1963), 1081–1094.

The author presents a modified formulation of Yukawa's bilocal field theory [Phys. Rev. (2) **77** (1950), 219–226; MR **11**, 567; ibid. (2) **80** (1950), 1047–1052; MR **12**, 571] in order to get a description of certain families of resonant states occurring in nature. These states, of increasing spins and alternating parities (such as the second and third isobars of the nucleon) cannot be correctly described by current local field theory, because the divergences which occur cannot be eliminated by renormalization. Indeed, previous studies [Fierz, Helv. Phys. Acta **23** (1950), 412–416; MR **12**, 67] had shown that, in the case of free fields, a bilocal field is equivalent to an infinite set of local fields of increasing spins and alternating parities. In the present work, an interaction is introduced, and an example is taken of a bilocal scalar field (the "nucleon") coupled with a local scalar field (the "pion"). It is shown that all the fields composing the bilocal nucleon field must have a nonlocal coupling with the pion, i.e., some "form-factors" have to be introduced in the interaction. The behaviour of such form factors is studied in detail, and two possible solutions are given, which preserve macrocausality, at least at low energies. The most interesting conclusion from this analysis is that in the limit where the characteristic length defining the nonlocality of the interaction goes to zero, all the form factors of the higher-spin fields vanish identically, and only the lowest-spin state survives. In other words, the existence of resonant states is intrinsically connected to the nonlocal character of the theory. Finally, the problem of quantization is discussed, and it is shown to be easily solved. It still remains an open question whether the families of particles described by this theory can be identified with those observed in nature.

Rosen, Mervine; Yennie, Donald R. 4469

A modified WKB approximation for phase shifts.

J. Mathematical Phys. **5** (1964), 1505–1515.

Authors' summary: "Extending an idea of Good, a modified WKB approximation using radial wavefunctions having the form of free-particle solutions to the radial wave equation rather than an exponential form is developed. The lowest-order phase shifts are the same as those of the usual WKB approximation, but are improved by the contribution of the next order. The method is applied to two examples: the radial Dirac equation in the high-energy limit and the radial Schrödinger equation."

Schroer, B. 4470

The concept of nonlocalizable fields and its connection with nonrenormalizable field theories.

J. Mathematical Phys. **5** (1964), 1361–1367.

A field with a very singular behavior at small distance is investigated. Wightman functions of a field with a test function in $\mathscr{D}_z$ has a short distance behavior not worse than some inverse power of the distance. A field which does not have this property is called nonlocalizable by the author. Any infinite Wick power series is an example. The following examples are studied in detail. (1) $B(x)=\,:e^{gA(x)}:$. The two-point function is $\exp[ig^2\Delta^{(+)}(\xi)]$ which is analytic in a cut plane and has an essential singularity at the light cone. (2) $B(x)=\,:e^{gA(x)^2}:$. The two-point function is $i\Delta^{(+)}(\xi)\{1+[2g\Delta^{(+)}(\xi)]^2\}^{-1}$ and is singular at spacelike ξ satisfying $2gi\Delta^{(+)}(\xi)=1$. In these examples, the Lehmann weight has an exponential increase (of the order $\frac{1}{2}$ for (1) and worse for (2)) and the Green's function cannot be defined.

The author feels that nonrenormalizable field is nonlocalizable and supports this belief by an example of a spinor field ψ having a coupling $\bar\psi\gamma^\mu\psi\partial_\mu A$ with a zero mass scalar field A. Taking only those self-energy diagrams with uncrossed multiple bosons, the author obtains the two-point function $-2\gamma^\mu\xi_\mu\{I_2[g\sqrt{3}/\pi\sqrt{z}]/3g^2z\}$, $z=-\xi^2$ for mass zero ψ, which has an essential singularity at the light cone. Alternatively, the replacement of A with a free field yields the free two-point function of ψ multiplied by $\exp[ig^2\Delta^{(+)}(\xi)]$, in which the contributions from graphs with crossed boson lines increase the bad behavior.

The nonexistence of Green functions for a nonlocalizable theory is not necessarily an obstacle for the scattering theory. The author exhibits the following computational prescription for elastic scattering amplitude: $\langle p'|\tilde{A}(q)\times \tilde{j}(-k)|p\rangle$ has the form $i[P/(q^2-m^2)]F-i\pi\delta(q^2-m^2)G+H$ near $q^2=m^2$ and the scattering amplitude is given by $T=(G+iF)/(2\pi)^3$.

Finally, the author suggests the possibility that in cases of practical interest, nonlocalizability appears only for nonobservable fields like spinor fields or charged fields and that local observables are well-defined.

H. Araki (Kyoto)

Gruber, B.; O'Raifeartaigh, L. 4471

Uniqueness of the harmonic oscillator commutation relation.

Proc. Roy. Irish Acad. Sect. A **63**, 69–73 (1964).

Starting with the generalized harmonic oscillator Hamiltonian $H=\mu aa^+ + (1-\mu)a^+a$, μ any real number, the commutation relation $[H, a] = -a$, and the assumption that H has a point spectrum and a least eigenvalue, a short proof of the following results is given. (a) There exists an operator A satisfying the above relations for a with $\mu=0$ (except for a trivial shift of the zero point energy); (b) the only commutation relations for A allowed are $[A, A^+]=1$, $[A, A^+]_+=1$, or that corresponding to para-Fermi statistics.

R. Ingraham (University Park, N.M.)

Scharfstein, H. 4472

Trilinear commutation relations between fields. (Italian summary)

Nuovo Cimento (10) **30** (1963), 740–761.

Author's summary: "A set of trilinear equal-time commutation relations is derived from Schwinger's action principle under the assumption that for equal times the field variations commute with bilinears of field operators. Some consequences of these trilinear equal-time commutation relations are investigated and representations of the operators which satisfy them are considered."

Morimoto, Tetsuzo 4473

Markov processes and the H-theorem.

J. Phys. Soc. Japan **18** (1963), 328–331.

Author's summary: "The H-theorem is investigated in view of Markov processes. The proof is valid even in fields other than physics, since no physical relations, such as the principle of microscopic reversibility, the unitarity of the S-matrix and so on, are utilized. The well-known 'Wiederkehreinwand' is also re-examined from this point of view and a reconciliation is regained between the H-theorem and the recurrence in the sense of probability theory."

Ingraham, R. L. 4474

Consequences of a fundamental length in very-high-energy scattering. (Italian summary)

Nuovo Cimento (10) **32** (1964), 323–355.

Author's summary: "We show that a fundamental length provides the mechanism in quantum field theory to produce the effects noticed in very-high-energy scattering. In the very-high-energy large momentum-transfer (s, $|t| \gg \lambda^{-2}$, $\lambda \equiv$ fundamental length) approximation already semi-quantitative agreement with the following features is obtained. (1) Detailed shape of the elastic scattering curves, including: very sharp forward (and sometimes backward) 'diffraction' peaks with universal exponential tails in t (or u), the 'flattening' and huge experimental 'shrinking of the diffraction peak' with energy of the p-p curves, the weak 'flattening' and absence of 'shrinking' of the π-p curves. (2) Asymptotic constancy of total cross-sections, asymptotic equality of $\sigma_{tt}(\pi^- \text{-}p)$ and $\sigma_{tt}(\pi^+ \text{-}p)$, the rough relation $\sigma_{tt}(\pi\text{-}p) \approx \frac{2}{3}\sigma_{tt}(p\text{-}p)$. One characteristic of $\lambda \neq 0$ is the rapid vanishing of higher-order corrections at high energies and of radiative corrections at large momentum transfers. With $\lambda = 0$, this is not so, the sharp peaking and exponential tails disappear, and the 'shrinking' of the p-p peak is far too small. An essential 'dynamical' assumption is that a neutral vector meson may be exchanged. These experiments indicate $\lambda \approx 10^{-14}$ cm; the vector meson mass is not yet clear. The fundamental-length field theory used requires an explicit dependence of the S-operator on the measuring frame (frame in which the experiment is performed); it is believed that any relativistically invariant, etc., fundamental-length theory requires this generalization of field theory. This 'kinematical' fundamental-length-theoretic and the 'dynamical' Regge pole explanations of very-high-energy scattering are compared point by point; they are clearly distinguishable at ultra-high momentum transfers. A $\lambda \neq 0$ implies changed asymptotic properties of analytic amplitudes (essential singularities at infinity), thus changes in the physical conclusions derived from dispersion relations."

F. Calogero (Rome)

★**Dispersion relations and their connection with causality.** 4475

Proceedings of the International School of Physics "Enrico Fermi", Course XXIX, Varenna on Lake Como, Villa Monastero, 15th July–3rd August 1963. Edited by E. P. Wigner.

Academic Press, New York-London, 1964. xvi + 256 *pp.* (1 *plate*) $12.00.

Seven lecture courses on current topics in dispersion relation techniques and a preface on invariance principles are collected in this book. These articles will be reviewed separately.

P. Roman (Boston, Mass.)

Wigner, E. P. 4476

The role of invariance principles in natural philosophy.

Dispersion Relations and Their Connection with Causality (*Proc. Internat. School of Phys. "Enrico Fermi", Course XXIX, Varenna*, 1963), *pp.* ix–xvi. *Academic Press, New York*, 1964.

The role and place of invariance principles in physics; the nature, development, inter-relation of invariance principles; their possible epistemological value in the future are given a short, but delightful discussion.

P. Roman (Boston, Mass.)

Froissart, M. 4477

The proof of dispersion relations.

Dispersion Relations and Their Connection with Causality (*Proc. Internat. School of Phys. "Enrico Fermi", Course XXIX, Varenna*, 1963), *pp.* 1–39. *Academic Press, New York*, 1964.

The basic features and methods of deriving specific dispersion relations in the framework of axiomatic quantum field theory are presented. The reduction formulae and the Jost-Lehmann-Dyson formulae, forward dispersion relations, the Lehmann ellipse, non-forward dispersion relations, and a critical evaluation of the results is the content of this review.

P. Roman (Boston, Mass.)

Causality, *R*-matrix, and collision matrix.

Dispersion Relations and Their Connection with Causality (Proc. Internat. School of Phys. "Enrico Fermi", Course XXIX, Varenna, 1963), pp. 40–67. Academic Press, New York, 1964.

The analytic properties of the R-matrix are proved, first directly, then from the principle of macroscopic (phenomenological) causality. Then the collision matrix is expressed in terms of the R-matrix and its analytic properties are determined. Many-channel processes are considered. *P. Roman* (Boston, Mass.)

Wong, D. Y. 4479

Dispersion relations and applications.

Dispersion Relations and Their Connection with Causality (Proc. Internat. School of Phys. "Enrico Fermi", Course XXIX, Varenna, 1963), pp. 68–96. Academic Press, New York, 1964.

After a brief recapitulation of the relation between causality and analyticity, elementary perturbation theory is used to illustrate poles of amplitudes, unitarity, and the crossing relations. The N/D method is introduced, and the difference between elementary and bound-state (and ghost) poles is demonstrated. Then the N/D method is used to discuss the elastic pion-nucleon scattering, with the main result that the 3,3 resonance and the nucleon pole can be treated on the same dynamical basis. A similar consideration is given to nucleon-nucleon scattering. Finally, electromagnetic form factors and the inclusion of strange particles are briefly discussed.
P. Roman (Boston, Mass.)

Newton, R. G. 4480

The nonrelativistic angular-momentum plane.

Dispersion Relations and Their Connection with Causality (Proc. Internat. School of Phys. "Enrico Fermi", Course XXIX, Varenna, 1963), pp. 97–134. Academic Press, New York, 1964.

A very thorough discussion of the analytic behavior in the complex angular momentum plane is given relative to the solutions of the non-relativistic Schrödinger equation. Simple models of particles with spin and of many-channel processes, as well as a model of the three-body problem, are also considered.
P. Roman (Boston, Mass.)

Landshoff, P. V. 4481

Production amplitudes.

Dispersion Relations and Their Connection with Causality (Proc. Internat. School of Phys. "Enrico Fermi", Course XXIX, Varenna, 1963), pp. 135–166. Academic Press, New York, 1964.

This review is concerned with the difficult properties of production amplitudes, as far as they can be discerned from perturbation theory. The discussion starts with the consideration of the unitarity condition, and then summarizes the analytic properties of production amplitudes. A discussion of partial wave amplitudes is then given. This is followed by a brief review of general higher amplitudes, i.e., the discussions are extended to other than five-point functions. The review ends with comments on the asymptotic behavior. *P. Roman* (Boston, Mass.)

Oehme, R. 4482

High-energy scattering and dispersion theory.

Dispersion Relations and Their Connection with Causality (Proc. Internat. School of Phys. "Enrico Fermi", Course XXIX, Varenna, 1963), pp. 167–256. Academic Press, New York, 1964.

The first section of this lucid review establishes, by way of plausibility arguments, various connections between high-energy limits of scattering amplitudes in a given channel and the single-particle states associated with the crossed channels. The second section introduces the complex angular momentum plane in a systematic manner, starting with the dispersion relations in momentum transfer and establishing the interpolation function. In the following, the connection between singularities of the interpolation function in the angular momentum plane and the high-energy properties of the scattering amplitude in the crossed channels is studied, and the properties of Regge poles are established. Then the possibility of elementary poles is explored. In Section 5 the nature of singularities in the angular momentum plane is further studied, and distinction between allowed and forbidden singularities is made. Section 6 discusses the asymptotic effects of the Sommerfeld-Watson representation and also places restrictions on possible "elementary" vector meson poles. In Section 7 the factorization of Regge poles and the Pomeranchuk theorem are discussed. Next, the possibility of pole condensation and of moving branch points is studied. Section 9 reviews the experimental situation and presents models for diffraction scattering. Finally, in Section 10 perturbation theory is used to show how bound-state Regge poles can be obtained by summing ladder graphs, and also the Regge treatment of single-particle poles is studied. *P. Roman* (Boston, Mass.)

Jones, C. Edward 4484

Consistency of the strip approximation.

Phys. Rev. (2) **135** (1964), B214–B219.

Author's summary: "An investigation is made to determine those properties demanded of the Regge-pole formulas used by Chew and Jones in order to ensure the consistency of the strip approximation. A study of the asymptotic behavior of the Regge parameters based on the dynamical equations is also made in relation to the same question. The conclusion is drawn that the dynamical equations appear capable of producing solutions that are essentially self-consistent with the strip approximation that was used as an input. The Chew-Jones Regge-pole formula is also compared with one suggested earlier by Khuri." *E. Predazzi* (Turin)

Chew, Geoffrey F.; Jones, C. Edward 4485
New form of strip approximation.
Phys. Rev. (2) **135** (1964), B208–B213.
Authors' summary: "A detailed set of 'bootstrap' equations is formulated for zero-spin 'external' particles based on a combination of the N/D method with the superposition of top-ranking Regge poles in all three reactions of a four-line connected part. The contribution from each pole arises from a distinct strip in the Mandelstam representation so that double counting is avoided. Only real values of l with $l \leq 1$ need be considered in the bootstrap calculation. The amplitude emerging from our N/D equations is meromorphic in the right-half l plane, and the Regge poles approach high-energy limits that are dynamically determined and which in some cases may lie to the right of $l=0$. The reduced residues vanish in the high-energy limit." *E. Predazzi* (Turin)

Kim, Y. S. 4486
Anomalous thresholds and three-particle unitarity integral.
Phys. Rev. (2) **132** (1963), 927–929.
Author's summary: "Anomalous thresholds of the square diagram and their effect on the two-particle unitarity integral are discussed. It is shown for a certain diagram that the three-particle unitarity integral does not have counter terms which cancel the singularity from the two-particle contribution. Consistency with the crossed-channel unitarity is also discussed."

Khrustalev, O. A. [Hrustalev, O. A.]
Regge poles and perturbation theory.
Nuclear Phys. **49** (1963), 170–176.
Authors' summary: "The contributions of the cuts in the l-plane to the scattering amplitude are investigated. A way of separating the pole terms is discussed. These terms should be understood as the main ones in the expansion in powers of $e^2m(m^2-E^2)^{-1/2}$."

Minguzzi, A. 4488
One-variable dispersion relations. (Italian summary)
Nuovo Cimento (10) **32** (1964), 198–211.
In the scattering process $A+B \to C+D$, with the masses of the particles A, B, C and D unequal, there is an unphysical region which makes the proof of dispersion relations difficult. In the Bogoliubov method one first establishes the dispersion relation for a negative value of the mean mass $\rho = 1/2(p_B^2+p_D^2)$, where p_B, p_D are the 4-momenta of particles B and D [see H. Lehmann, Nuovo Cimento (10) **14** (1959), suppl., 153–176; MR **23** #B824]. The "unphysical" dispersion relation is then

$$(1)\quad T(\omega,\rho) = \frac{1}{\pi}\int_{s_0}^{\infty} \frac{A_1(s,\rho)\,ds}{s-\rho-\mu^2-2\Delta^2-2\omega E_\Delta} + \int_{s_0}^{\infty} \frac{A(u,\rho)\,du}{u-\rho-\mu^2-2\Delta^2+2\omega E_\Delta},$$

where Δ is the momentum transfer and

$$2E_\Delta = (2M_A^2+2M_C^2+4\Delta^2)^{1/2}.$$

One hopes to continue the absorptive parts $A(s,\rho)$ as an analytic function of ρ to its physical value $\rho^{ph} = 1/2(M_B^2+M_D^2)$.

One theorem of the present paper shows that if s, the square of the centre-of-mass energy, is above its physical threshold s^{ph}, then it is relatively easy to prove that $A(s,\rho)$ is an analytic function of ρ in the desired region, namely, Re $\rho \leq \rho^{PH}$ and $|\mathrm{Im}\,\rho| < \delta$, for some $\delta > 0$ independent of s. The method uses the Jost-Lehmann-Dyson representation as applied by Lehmann [see the above reference and also A. S. Wightman, Relations de Dispersion et Particules Élémentaires (Grenoble, 1960), pp. 227–315, esp. pp. 219–307, Hermann, Paris, 1960; MR **26** #3927]. This is not sufficient to prove a dispersion relation since in equation (1) we have no knowledge of the analytic properties of $A(s,\rho)$ in the unphysical region $s_0 \leq s \leq s^{ph}$.

The author remarks that the contribution G to T in (1) due to $s \geq s^{ph}$ and $u \geq u^{ph}$ (i.e., the physical ranges) is, because of the above-mentioned theorem, an analytic function of (ω,ρ) in two wedge-shaped regions joined at the edge. Causality implies that T itself also has this property, and a calculation shows that the boundary values of $T-G=F$ taken from the two regions of analyticity are equal in the physical region. Thus F satisfies the conditions of the edge of the wedge theorem, and so is real analytic in a neighbourhood of the physical region in both ω and ρ. This shows that T is an analytic function of ρ in the physical region, and the physical amplitude is the boundary value of a function analytic in ω.

Newton, Roger G. 4489
Nonrelativistic S-matrix poles for complex angular momenta.
J. Mathematical Phys. **3** (1962), 867–882.
Author's summary: "Regge's introduction of complex angular momenta is studied in more detail. The shape and number of trajectories of S-matrix poles as functions of the energy is investigated, with particular attention to the way they leave the real axis, and to their ends at $E \to \pm\infty$. The conditions are found under which the S-matrix is meromorphic even in Re $l < -\frac{1}{2}$. Some properties of the S-matrix in the left half-plane are discussed and so are its symmetry between the left and right half-planes, its branch point at $E=0$, and the residues at its poles."

W. A. Benjamin, Inc., New York-Amsterdam, **1964.** vi+248 *pp.* **$9.00.**

This lecture-note volume contains seven theoretical reviews on current topics in elementary particle physics and five illustrative seminar notes on associated experimental topics.

The first chapter gives a general introduction to the whole set of lectures. It discusses, in an easily understandable and introductory exposition, the S-matrix idea, elements of quantum field theory, and the basic features of strong, electromagnetic, and weak interactions. The second chapter is a survey of various topics in non-relativistic potential scattering, including the highlights of Regge theory. The next chapter discusses, by means of phenomenological analysis, inelastic collisions and shadow scattering of strongly interacting particles at high energy. This is followed by an equally brief introduction to higher symmetry schemes, in particular, SU_3. The next chapter discusses various pion resonances, both from the dynamical and from the symmetry point of view. Next, a rather detailed review of weak interaction physics is given which emphasizes more the highlights than the details. The role of SU_3 symmetry in the leptonic decays of strongly interacting particles is the topic of the last theoretical chapter.

The experimental seminars deal with proton-antiproton collisions, proton-proton and pion-proton high energy elastic scattering, questions related to the η-meson μ-pair production, and radiative-capture.

Sakurai, J. J. 4492

★Invariance principles and elementary particles.
Investigations in Physics, No. 10.
Princeton University Press, Princeton, N.J., 1964. x + 326 *pp.* \$8.50.

This monograph appears to have a multiple purpose: (a) to give a first and selective introduction to students in theoretical physics concerning the most fundamental features of elementary particle theory, and (b) to acquaint experimentalists, in a relatively painless manner, with theoretical issues relevant in their work. In addition, the more advanced student in elementary particle theory will also profit from the treatise, since many concepts and subtleties which are given only a superficial and inadequate treatment in the existing literature have been clarified and illuminated by the present author.

The book starts with a brief general characterization of continuous space-time transformations. This is followed by chapters on parity, time reversal, charge conjugation and the CPT theorem. Chapter 7 discusses γ_5 invariance in weak interactions. Chapter 8 is devoted to gauge transformations and "Number Laws". The next two chapters describe isospin invariance and many ramifications thereof. The last chapter, entitled "Unsolved Problems", calls attention to a number of puzzles and is sprinkled with "notes added in proof".

The style and presentation is, in general, clear and sometimes terse. Occasionally, however, a somewhat less condensed treatment or a more systematic approach might have been advisable.

{A comment is in place concerning editorial policies. This book is based on a graduate course which the author gave in early 1959. Although he clearly made a strong effort to incorporate further developments, it appears that the manuscript has reached the publisher not later than 1961. The most exciting developments did not get into the book; for example, unitary symmetry is mentioned in two sentences only which were added in proof. It appears most puzzling why it took the publisher two years or more to bring out the book, precisely when the field in question is in such an unbelievably rapid development.}

P. Roman (Boston, Mass.)

Schmutzer, E.; Weber, G. 4493

Zur nichtrelativistischen zweiten Näherung der Diracschen Theorie des Elektrons. (English summary)
Annuaire Univ. Sofia Fac. Sci. Phys. Math. Livre 2 Phys. **55** (1960/61), 105–115 (1962).

It is shown that the same nonrelativistic Schrödinger equation can be obtained by eliminating the two "small components" from the Dirac equation, followed by a two-parameter family of transformations to a Hermitian Hamiltonian, as can be obtained by directly decoupling the two two-component spinors by a unitary Foldy-Wouthuysen transformation of the Dirac equation.

Garrido, L. M.; Sesma, J. 4494

Observables of relativistic particles. (Spanish. English summary)
Collect. Math. **14** (1962), 279–286.

Authors' summary: "We study the most general unitary transformation that transforms the Hamiltonians of particles of spins 0, 1/2 or 1, into Hamiltonians containing even or odd matrices only. We present also the expressions for the position operators for each transformation that are valid for the three kinds of particles mentioned above."

Hagen, C. R. 4495

Resonances in multichannel systems.
Phys. Rev. Lett. **12** (1964), 153–155.

The scattering matrix is considered in a model problem that has two coupled s-wave channels. The movement of bound states and resonances on the sheets of the Riemann surfaces are discussed. It is shown that crossings from one sheet to another require special assumptions on the energy dependence of the matrix elements. The purpose of this note is to refute arguments that suggest that the unitary symmetry model may be suspect, because the resonances would have to change sheets as the symmetry-violating interactions varied from zero strength to their actual values.

F. R. Halpern (La Jolla, Calif.)

Hagen, C. R.; Macfarlane, A. J. 4496

Triality type and its generalization in unitary symmetry theories.
J. Mathematical Phys. **5** (1964), 1335–1339.

Authors' summary: "Within the context of an extension of the SU_3-symmetry theory recently suggested by Gell-Mann and further developed by the authors, certain aspects of the theory of the special unitary groups are examined. The plurality type of a given representation is introduced as the generalization of the triality concept to SU_{n+1} and is shown to be associated with a multiplicative conservation law. Theorems for the reduction of representations of SU_{n+1} with respect to SU_n, $U_1^{(n)}$ are derived

which are subsequently used to relate plurality type to the existence of fractional eigenvalues for the generator $Y_1^{(n)}$ of $U_1^{(n)}$." *G. Heber* (Leipzig)

Gerstein, I. S. 4497

Virtual particles and the baryon-baryon system. (Italian summary)

Nuovo Cimento (10) **32** (1964), 1707–1714.

Author's summary: "The ${}^1S_0$ virtual bound state of the nucleon-nucleon system is shown to belong to the 27-dimensional representation of the symmetry scheme based on SU(3), known as the eight-fold way. The other states of this multiplet are derived. Experimental evidence bearing on this state is discussed and it is suggested that if the many complications of baryon number-2 states can be disentangled they can provide a fertile field for studying the validity of SU(3)."

{Reviewer's remarks: The (conjectured) approximate symmetry of strong interactions under SU(3) should not be expected to characterize the low-energy behavior of the two-baryon system. The far longer range of pion-mediated forces precludes the relevance, in this regime, of any symmetry scheme mixing pions and kaons.}

Fairbairn, W. M.; Fulton, T.; Klink, W. H. 4498

Finite and disconnected subgroups of SU_3 and their application to the elementary-particle spectrum.

J. Mathematical Phys. **5** (1964), 1038–1051.

From the authors' summary: "The techniques previously employed by Case, Karplus, and Yang [Phys. Rev. (2) **101** (1956), 874–876; MR **17**, 923] for the application of finite subgroups of SU(2) to isotopic spin are extended to the (finite and disconnected) subgroups of SU(3). As a first step, character tables, irreducible representations, and other relevant properties are derived for these subgroups. Next, the classification of elementary particles is made on the basis of the representations of these subgroups. The structure of SU(3) is utilized to suggest how charge and hypercharge operators are to be assigned in the subgroups. The results obtained are similar to those of SU(2) and isotopic spin. In particular, there exist finite subgroups of SU(3) which can accommodate the eight baryons in one of the irreducible representations. In scattering problems, however, use of the finite subgroups gives charge or hypercharge conservation only modulo an integer determined by the subgroup. Charge independence is also lost. Exact charge and hypercharge conservation can be maintained for the disconnected subgroups, but the maximum dimension of the irreducible representations is six, and only charge symmetry, not charge independence, is satisfied. A short discussion of the representations of the group $SU(3)/C$ (C = center) is included in the appendix."

Gürsey, F.; Radicati, L. A. 4499

Spin and unitary spin independence of strong interactions.

Phys. Rev. Lett. **13** (1964), 173–175.

It is claimed that the group SU(4), introduced by Wigner to classify nuclear states, can be extended to the relativistic domain and that it may be relevant to elementary particle physics. Containing both the 3-dimensional spatial rotation group and the isotopic-spin group as sub-groups, Wigner's group expresses the spin and isotopic spin independence of nuclear forces. Associated with the adjoint representation of SU(4) are the mesons ρ, ω, and π (15 distinct particles with spin and isotopic spin taken into account). The nucleons and the $\frac{3}{2}$-$\frac{3}{2}$ pion-nucleon resonance are accommodated in a 20-dimensional irreducible representation. By replacing the isotopic spin group by SU(3), a symmetry scheme involving SU(6) is obtained. The adjoint representation is 35-dimensional and it describes the octet of pseudoscalar mesons and a nonet of vector mesons. The baryon octuplet and the $j=\frac{3}{2}^+$ decuplet of meson-baryon resonances are accommodated in a 56-dimensional representation. The existence of some spin-dependent forces is invoked in order to explain the mass splittings between vector and pseudoscalar mesons and between baryons and resonances. It is by no means evident {and, this reviewer denies} that the models discussed do have the invariance properties under SU(4) or SU(6) that are claimed. In this connection, the authors refer to a forthcoming paper of theirs.

Pais, A. 4500

Implications of spin-unitary spin independence.

Phys. Rev. Lett. **13** (1964), 175–177.

The SU(6) model of strong interaction symmetry [F. Gürsey and L. Radicati, #4499] is further developed. A conjectured mass formula for the ($j=0^-, 1^-$) mesons, and one for the ($j=\frac{1}{2}^+, \frac{3}{2}^+$) baryons, are approximately satisfied by experimental masses. The form of the Yukawa meson-baryon coupling is unique and involves both symmetric "D-type" and antisymmetric "F-type" interactions with a determined ratio. Meson-baryon resonances are considered in the light of this symmetry scheme, and the possible existence of a 70-plet of $j=\frac{3}{2}^-$ states is suggested. *S. L. Glashow* (Berkeley, Calif.)

Bell, J. S. 4503
Nuclear optical model for virtual pions.
Phys. Rev. Lett. **12** (1964), 57–59.
This paper contains an evaluation of the cross-section of virtual pions on large nuclei. It is of possible use for the explanation of certain reactions (e.g., lepton production by neutrinos on nuclei, which can be explained by the one-pion-exchange model). The author shows that the optical model, used for collisions of real pions on nuclei, can be generalized to virtual pions. However, the effect of a new term in the equations, that vanishes for real pions, makes the absorption rate proportional to the volume of the nucleus. Consequently, this absorption rate is linear in the atomic number A, whereas real-pion absorption goes roughly like $A^{2/3}$. The contribution of this linear term to the cross-section is less than the sum of the cross-sections on the individual nucleons, and decreases with increasing virtual-pion energy.

On a universal six-dimensional space of events. (Russian)
Vestnik Moskov. Univ. Ser. III Fiz. Astronom. **1963**, *no.* 6, 23–34.
The sixth dimension is added to the five-dimensional theory of Kaluza and Klein in order to include a hypothetical vector gauge-field coupled to baryonic charge. The 6-space is closed in the fifth and the sixth dimension to give quantized electric and baryonic charges and to prevent ordinary space-time from mixing with two added coordinates. Classical field equations in this theory are proposed. *I. Białynicki-Birula* (Warsaw)

Rylov, Ju. A. 4507
Particles with half-integer spin in a universal 6-dimensional space. (Russian)
Vestnik Moskov. Univ. Ser. III Fiz. Astronom. **1964**, *no.* 3, 3–14.
The present paper, as a continuation of the preceding [#4506 above], deals with the spinor equation in the 6-dimensional space (the sense of the last two coordinates is stated through the corresponding momenta which represent the electric and baryonic charge, respectively; all physical quantities are periodic functions of these two coordinates). The introduction of spinors in 6-space allows one to consider all elementary particles as the various states of one 6-dimensional Fermi-field. However, for instance, the mass spectrum or other interesting properties of interacting particles can be obtained after the second quantization of these fields.

Vachaspati; Punhani, Sudarshan L. 4508
Electromagnetic field of a charged particle in uniformly accelerated motion.
Proc. Nat. Inst. Sci. India Part A **29** (1963), 501–519.
Authors' summary: "A uniformly accelerated charged particle is peculiar in that it gives rise, at any given space-time point, either to a retarded or to an advanced electromagnetic field, but not to both. On general grounds one expects both kinds of fields to exist at all space-time points. The mathematical reason why only one kind of field exists in the case of uniform acceleration is pointed out and a limiting procedure is introduced to overcome the difficulty. It is then possible to obtain both kinds of fields at all points excepting the boundaries of some regions. The field at these boundaries can be determined by requiring that it should eliminate the presence of any unphysical charges. The solutions at these boundaries are not unique. Explicit expressions for the potentials and the fields are given. Our results partly confirm those of Bondi and Gold [Proc. Roy. Soc. London Ser. A **229** (1955), 416–424; MR **16**, 1166]."

The structure of the nucleon core by the Hartree approximation.
Nuclear Phys. **26** (1961), 658–669.
Author's summary: "A method is proposed to investigate the structure of the nucleon core. A set of equations is derived to define the nucleon core and the meson cloud simultaneously. The equations are formulated by a variational method which enables us to find an approximate solution. The size of the nucleon core is estimated for a non-relativistic nucleon interacting with a neutral scalar meson. The coupling constant between nucleon and meson is given by the ratio of the sizes of the core and the cloud. It is shown that for $f^2/4\pi \approx 1$, the core size may be about half that of the meson cloud, where the number of mesons around the nucleon is about one. The generalization to a more realistic case is also suggested. The renormalization is not considered in this paper."

Bahtadze, A. K. 4510

On the solution of the equations of one-dimensional cascade theory of electron-photon showers with arbitrary boundary conditions and in the form of a source function. (Russian)

Vestnik Moskov. Univ. Ser. III Fiz. Astronom. **1964**, *no.* 3, 28–37.

In this paper the author obtains approximate solutions of equations of one-dimensional cascade theory of showers in the case of arbitrary boundary conditions and form of source functions. The method used permits one to obtain the general form of the distribution function of the number of particles without taking any particular form of the boundary conditions and source functions. This makes it convenient to compare the theory with experimental results. A new form of a source function is considered which is applicable to broad atmospheric showers. *P. K. Ghosh* (Calcutta)

Conservation of particle number in the nuclear pairing model.

Phys. Rev. (2) **135** (1964), B22–B34.

A trial wave function of pairing type which conserves the number of particles is used in a variational calculation with a δ-function interaction. The results are compared with results from a BCS wave function (particle non-conserving), and from using a BCS wave function with subsequent projection onto the given particle number. Individual level occupation probabilities are altered by up to 60% in unfavourable cases (weak pairing interaction, low occupation probability), but are usually correct to within 10–20%. On the other hand, neglect of particle conservation frequently results in a qualitatively different spectrum of excitation energies of a nucleus. *J. M. Blatt* (Kensington)

Modern methods in the theory of many-phonon processes.

Uspehi Fiz. Nauk **80** (1963), 553–595 (*Russian*); *translated as Soviet Physics Uspekhi* **6** (1964), 542–565.

The author reviews modern theories of many-phonon processes in solids, particularly those associated with localized electronic states. The emphasis is put on the theoretical methods rather than the physical facts. It includes the method of using generating functions, the method of moments, Green's function formulation, etc. *R. Kubo* (Tokyo)

Sen, D. K. 4513

A theoretical basis for two neutrinos. (Italian summary)

Nuovo Cimento (10) **31** (1964), 660–669.

The object of this paper is to show how an antisymmetric tensor of rank two can be split up in a covariant manner into the sum of a self-dual term and an anti-self-dual term, each giving rise to a form of the two-component Weyl equation for a neutrino. The two neutrinos will behave identically when they are free but their interactions with other particles may be different.

The second of Maxwell's equations is shown to be satisfied by this tensor. This implies that such a combination of two neutrinos can be considered as an example of an electromagnetic field, though it is by no means obvious that such a field corresponds to a physical photon. *I. M. Barbour* (Rome)

Kónya, A. 4514

Über die Reihenfolge der Besetzung der Quantenzustände in Atomen. (Russian summary)

Acta Phys. Acad. Sci. Hungar. **13**, 219–231 (1961).

Jensen and Luttinger [Phys. Rev. (2) **86** (1952), 907–911] have found a good agreement between the experimental dependence of average square of the total angular momentum of atoms on the atomic number Z and the theoretical dependence calculated by means of statistical atomic theory. In the present paper the same agreement is obtained for the average total angular momentum, $\langle L\rangle$, and its average z-component, $\langle L_z\rangle$. The corresponding statistical formulae for $\langle L\rangle$ and $\langle L_z\rangle$ are given.

On the other hand, the results of the statistical model are compared with those obtained by simple summations of the azimuthal quantum numbers of the atoms where Z is assumed to be great. A very good agreement between both calculations is attained if one assumes that the electrons occupy the quantum levels in the sequence close to this which is known from experiment. *S. Olszewski* (Warsaw)

On the interaction between two identical neutral dipole systems, one in an excited state and the other in the ground state.

Mathematika **11** (1964), 91–94.

It is found that the virtual exchange of transverse photons diminishes the interaction between two identical dipoles when one of them is in an excited state. *N. S. Wall* (College Park, Md.)

Glick, Arnold J. 4516

The linear response function of a many-body system.

The Many-Body Problem (Lecture Notes, First Bergen Internat. School of Physics, 1961), *pp.* 261–285. *W. A. Benjamin, New York*, 1962.

The first part of this lecture elucidates clearly the definition and properties of the linear "response function" in a many-body system. When an external field is turned on, a system in a state ψ_n will undergo transitions to other states exchanging energy with the field. In the linear approximation (suitable when the external field is weak) we use first-order perturbation theory, and the net rate of absorption from the field is given by

$$\frac{dE}{dt} = 2\pi\omega\left|\frac{V(k,\omega)}{2\pi\Omega}\right|^2[R_n(k,\omega)-R_n(k,-\omega)],$$

where $V(k,\omega)$ is one typical Fourier component of a field $V(r,t)$. The response of the system is characterised by the response function $R_n(k,\omega)$, which depends on the internal structure of the system and is given by

$$R_n(k,\omega) = \sum_m \delta(E_m-E_n-\hbar\omega)\left|\left\langle\psi_m\right|\sum_i e^{ik\cdot r_i}\left|\psi_n\right\rangle\right|^2.$$

In Sections 3 and 4 two integral rules for $R_n(k,\omega)$ are derived in a neat fashion, and it is shown that any two-body operator F of the form $F=\sum_{ij}F(r_i-r_j)$ can be

averaged over the system to yield $\langle F\rangle$, which can be related to the integral of the response function over ω.

This idea is used in relating scattering cross-sections in the Born approximation for a fast external particle to be scattered by a system losing momentum k, to the pair correlation function in the system through integrals over $R_n(k, \omega)$, thus making contact with the theory of van Hove for such processes. It is proved that the real part of the correlation between values of a one-body operator X at different times can be related to integral over response functions. Also, the dissipation of energy in a system in the ground state in interaction with an external field of the form $V(r, t) = f(t)X(r)$ (where $X(r)$ is a one-body operator) can be related to the integral over response functions. Therefore the fluctuations in X in equilibrium can be easily shown to be closely connected to the dissipation in energy, thus leading to the fluctuation-dissipation theorem. The response function itself is written in a more suggestive form

$$R_n(k, \omega) = \frac{1}{\pi}\operatorname{Re}\int_0^\infty ds e^{i\omega s}\langle\psi_n|e^{iHs}\rho_k{}^+e^{-iHs}\rho_k|\psi_n\rangle.$$

Mention is made of the simple linear relation of the response function with various other physical quantities like susceptibility, dielectric constant, etc. It is desirable that a direct connection between Green's functions, dielectric constants, etc., and the response functions might have been demonstrated in detail in the lecture.

From Section 7 onwards the lecture is devoted to the calculation of response functions in a Fermi system. To this end one has to calculate the matrix element $\langle\psi_0|e^{iHS}\rho_k{}^+e^{-iHS}\rho_k|\psi_0\rangle$ for $S>0$. In the second quantized form ρ_k is the operator which destroys a particle in a momentum eigenstate and creates another with momentum increased by k, and it has a role similar to an external field and is represented as such graphically. Feynman diagrams are drawn as in perturbation theory calculations in many-body theory introduced by Hubbard to represent time translation operators, etc., and the rules for drawing each graph are given in detail. In Section 8, the simple case of a non-interacting Fermi gas is investigated and $R_0(k, \omega)$ is derived. In Section 9, interacting systems are considered and $\Delta R(k, \omega)$, the correction to $R_0(k, \omega)$, is calculated in different orders of perturbation theory. It is shown that however small the strength of the interaction, provided it is not a delta function interaction and provided it is not zero, then perturbation theory is not valid for some k and ω. In Section 10, a distinction is made between the graphs which cannot be separated into two parts by cutting a single interaction line and those which can be separated by cutting a single interaction line. Attention is drawn to the entities $(1/\tau)B(x, x')$ which represents the polarization bubble parts between x and x' and $\nu(x, x')$, the effective interaction between x and x', which represents the sum of a class of elementary graphs which begin and end with simple interaction lines. Integral equations are written for these, by grouping certain classes of terms, and an expression for $R(k, \omega)$ in terms of Fourier transforms of $B(x, x')$ and $\nu(x, x')$ is obtained:

$$R(k, \omega) = \frac{\Omega}{2\pi^2}\operatorname{Im}\int_0^\infty ds\int d\omega' e^{i(\omega-\omega')s}\frac{B(k, \omega')}{1+\nu(k)B(k, \omega')}.$$

In Section 11, $B(k, \omega)$ is obtained by summing over the lowest-order graphs. For a system with repulsive interactions, $R(k, \omega)$ exhibits a strong peak for the vanishing of the denominator in the integrand of the above expression for $R(k, \omega)$ below a critical wave number k. For a system with Coulomb interactions this resonance is associated with plasma oscillations, and for finite range forces with zero sound. But for spinless fermions with a δ force, the interaction $R(k, \omega)$ is given by its value for the non-interacting case. Finally, the case of the electron gas (spin $\frac{1}{2}$ fermions with interaction $V(k) = 4\pi e^2/k^2$) is mentioned and the inadequacy of the approximation (the RPA) in which the response function is calculated using B^0, the uncorrected bubble contribution, is brought out.

★Lectures on the many-electron problem.

Interscience Monographs and Texts in Physics and Astronomy, Vol. X.

Interscience Publishers [*John Wiley & Sons*], *New York-London-Sydney*, 1963. viii + 204 *pp*. $9.50.

The field of the many-body problem is one of the most rapidly growing in present-day physics; this is quite natural if one considers that practically all physical problems can be viewed as particular cases of the many-body problem. Before this problem could be treated adequately, appropriate mathematical techniques had to be developed, and actually this field has adopted the great advances made recently in field theory. In its modern form the many-body problem is therefore a rather recent field, and the number of monographs published to date is still rather limited. We can therefore only welcome

the publication of this book which fills a gap in the literature. Indeed, this book is, in our opinion, the best existing text which would enable a student to learn the problem from the beginning up to the advanced level, and which treats a sufficient number of examples to give a good idea of the field of applicability of the methods.

Chapter 1 reviews the more important results of classical equilibrium statistical mechanics, such as the cluster expansion, the theory of plasma oscillations, the "random-phase approximation", etc. The presentation is simpler and more intuitive (although rigorous) than in usual texts. The stress is laid on the peculiarities introduced by the long-range forces.

Chapter 2 contains a very detailed exposition of the techniques of calculation, such as the perturbation expansion of the ground-state energy and the finite temperature expansion of the free energy.

Chapter 3 is devoted to a detailed calculation of the correlation energy of an electron gas in RPA. The two equivalent, but formally different, methods used here are the one due to Gell-Mann and Brueckner, based on summation of ring diagrams, and Sawada's method based on the exact solution of a simplified "pseudo-Hamiltonian". It is shown that the RPA correctly gives the high-density limit of the thermodynamic properties.

Chapter 4 is an exposition of the dielectric-constant approach to the many-body problem, originally due to Nozières and Pines. In this very elegant formalism it can be shown that all thermodynamic properties of a system in equilibrium can be expressed in terms of the dielectric constant of the system. The situation of the RPA in this formalism is discussed, as well as its links with the self-consistent field method.

Chapter 5 treats a number of applications of the formalism to the theory of metals. Among the topics discussed are the specific heat, the magnetic susceptibility, the characteristic energy loss, as well as a few indications on superconductivity.

All the calculations are done in great detail, with useful remarks stressing the delicate points. This feature, combined with a great clarity of the style, gives the book a significant pedagogical value. We strongly recommend these lectures to graduate students and to all research physicists in the fields of solid-state physics, statistical mechanics, plasma physics, nuclear physics, etc.

R. Balescu (Brussels)

Sandri, G. 4520

Global master equation. I. (Italian summary)
Nuovo Cimento (10) **32** (1964), 985–990.

The author derives a master equation for a classical system of interacting particles, using similar techniques as in his previous papers [Phys. Rev. Lett. 11 (1963), 178–179; MR 25 #4620; Ann. Physics 24 (1963), 332–379; ibid. 24 (1963), 380–418]. The basic smallness assumption is introduced in the following way. Let F be the normalized distribution function of the system in phase space, and Φ its configurational part; then it is assumed that (1) $(F/\Phi)-1\sim O(\varepsilon)$, and that Φ and F are of the form (2) $\Phi(t,\varepsilon t)=\Phi^{(0)}+\varepsilon\Phi'$; $F(t,\varepsilon t)=\Phi^{(0)}+\varepsilon F'$.

{The author interprets the condition (1) as characterizing the strength of the statistical correlation between the momentum and position degrees of freedom of the system. Moreover, he states that the validity of the resulting equation is independent of the details of the two-body potential. Both these remarks are obscure to the reviewer. First, assumption (1) need not be satisfied, in general, even in thermal equilibrium, in spite of the fact that then there is no correlation between positions and momenta; second, even in thermal equilibrium, the satisfaction of this assumption depends on the nature of the two-body potential.} *N. L. Balazs* (Stony Brook, N.Y.)

da Costa, R. C. T. 4521

On fluctuations in statistical mechanics. (Italian summary)
Nuovo Cimento (10) **32** (1964), 654–678.

A general discussion is given of the theory of fluctuations in microcanonical, canonical, and grand canonical ensembles. *D. ter Haar* (Oxford)

Conditions for optimal choice of approximate wavefunctions and the hypervirial theorem.
J. Chem. Phys. **41** (1964), 1991–1995.

Author's summary: "The hypervirial theorem for the operator L does not guarantee the independence of the expectation value L from all essential errors of the approximate wavefunction. The more complete system of conditions includes the matrix elements of higher commutators (and anticommutators) L with the Hamiltonian. These conditions prevent the effect of approximate wavefunction errors and may be useful for evaluations of expectation values and transition probabilities. The problem is considered in terms of dynamics or statics. These treatments are shown to be equivalent only for the exact solution."

Wichmann, Eyvind H. 4523

Density matrices arising from incomplete measurements.
J. Mathematical Phys. **4** (1963), 884–896.

Author's summary: "The problem of how to associate a statistical ensemble of a quantum mechanical system with an incomplete set of measured ensemble averages is discussed. The view adhered to in this note is that the most chaotic ensemble consistent with the measured ensemble averages is a reasonable choice of ensemble. The properties of this ensemble are studied rigorously for the case when the quantum mechanical system is associated with a finite-dimensional Hilbert space. The results are extended heuristically to some particular ensembles of many-boson and many-fermion systems."

Yaris, Robert 4524

Linked-cluster theorem and unitarity.
J. Chem. Phys. **41** (1964), 2419–2421.

Author's summary: "It is shown that the linked-cluster theorem for nonperturbational treatments (previously demonstrated) follows from the principle of unitarity (conservation of probability). The reason why unlinked clusters appear in CI calculations, but can be cancelled out of the results, is also briefly discussed."

Ninham, B. W. 4525

Specific heat of a degenerate electron gas.

Ann. Physics **28** (1964), 220–224.

Author's summary: "Computational errors in a calculation of the specific heat of a degenerate electron gas as computed by Du Bois [Ann. Physics 7 (1959), 174–237; MR 24 #B1567; ibid. 8 (1959), 24–77] are corrected."

Sherman, S. 4526

Product property and cluster property equivalence.

J. Mathematical Phys. **5** (1964), 1137–1139.

From the author's summary: "Uhlenbeck and Ford in their presentation of the Ursell development express a sequence of symmetric functions W_N in terms of another sequence of symmetric functions U_N. They invert this sequence of equations and remark that from the first set of equations it follows that the product property of the W_N sequence is equivalent to the cluster property for the U_N sequence. They ask for a simple proof of the equivalence. Here a modification of an algebra developed by Bohnenblust to prove Spitzer's formula on the fluctuations of the sums of independent, identically distributed, random variables is used systematically to invert the relations and to prove the equivalence under lighter assumptions than previously used."

Electrical conductivity of partially ionized gases. (Spanish. English summary)

An. Soc. Ci. Argentina **176** (1963), 45–55.

Authors' summary: "The authors calculate the conductivity of a partially ionized gas by solving Boltzmann's equations. Collision terms are found by expressing the velocity of a particle after the collision has happened as a function of the velocity before it, and for that the properties of the vector $\mathbf{K}=\mathbf{C}'-\mathbf{C}$ are used. The resultant conductivity has the same form as the conductivity calculated by means of the theory of mean free paths, but its terms are affected by correction factors."

Gold, L. 4528

On the wave mechanics of gases. (Italian summary)

Nuovo Cimento (10) **32** (1964), 1622–1628.

Some approximate expressions are derived for the thermodynamic functions and for the equation of state of a system of non-interacting particles obeying Boltzmann statistics. The transition from wave mechanics to kinetic theory is discussed. *H. B. Rosenstock* (Washington, D.C.)

Louck, J. D.; DeVault, G. P. 4529

Eigenfunctions of the Boltzmann collision operator.

Phys. Fluids **7** (1964), 1388–1390.

This is a simple and elegant derivation of the known fact that the oscillator wavefunctions are eigenfunctions of the Boltzmann collision operator in the case of Maxwellian interactions between the particles. *R. Balescu* (Brussels)

Naze, Jacqueline 4530

★Sur l'équation de Boltzmann des gaz faiblement ionisés.

Préface de Henri Cabannes.

Table of Contents: Chapitre I, Équation de Boltzmann; Chapitre II, Opérateurs collisionnels linéaires; Chapitre III, Opérateurs collisionnels particuliers. Gaz de Lorentz parfait et imparfait; Chapitre IV, Calcul exact de la conductivité électrique et de la température d'un gaz faiblement ionisé; Chapitre V, Grandeurs macroscopiques d'un gaz faiblement ionisé en deuxième approximation; Appendice I, Fonctions sphériques. Calcul de $\mathscr{C}_{l_0}(c)$ et de $(\partial/\partial c)\mathscr{C}_{l_0}(c)$; Appendice II, Propriétés des valeurs propres de l'opérateur K pour la loi en $1/r^5$; Appendice III, Variation de la conductivité électrique et de la température en fonction du champ magnétique et de la masse des particules.

Rose, Marian H. 4531

Drag on an object in nearly-free molecular flow.

Phys. Fluids **7** (1964), 1262–1269.

The steady linearized single relaxation kinetic model is considered for rarefied flow past a sphere. Denoting the mean-free-path by L, the sphere radius by a, then the lowest-order solution is found for distances R such that $a \ll R \leqq L$. This solution is then used to find the drag correction on the sphere. *L. Sirovich* (Providence, R.I.)

Ruelle, David 4532

Cluster property of the correlation functions of classical gases.

Rev. Modern Phys. **36** (1964), 580–584.

An algebraic formalism is set up to study the relationship connecting the various correlation and cluster functions used in the theory of fluids. This is used to obtain upper bounds on the integrals of the absolute values of the Ursell functions at zero density, and also at finite densities provided the fugacity is less than a specified quantity. The "cluster property" referred to in the title is the finiteness of these integrals. *O. Penrose* (London)

Struminskiĭ, V. V. 4533

On Hilbert's method of solving the kinetic Boltzmann equation. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 70–73.

It is shown that the Hilbert method of solution of Boltzmann's equation, based on an expansion in powers of a small parameter, is not appropriate for a dissipative fluid. In particular, it is shown that the Hilbert solution (contrary to the Chapman-Enskog solution) leads to equations of motion which are essentially different in structure from those describing a viscous fluid.

R. Balescu (Brussels)

Su, C. H. 4534

Kinetic theory of a weakly coupled gas.

J. Mathematical Phys. **5** (1964), 1273–1280.

The author considers the problem of the kinetic theory of gases by use of the multiple time scale method, first

invented by Poincaré in dealing with the perturbation of the orbits of celestial bodies, and applied here to the BBKGY hierarchy of coupled equations governing n-body distribution functionals. After an initial discussion of the physical problem and the relevant parameters, the author considers the weak coupling case and then higher-order approximations. Because the expansion considered is not valid for the case of small relative velocities between particles, a new expansion valid for this case is formulated to first order only. A discussion and analysis of the kinetic equations of the one-particle function which then follows concerns itself with the rate of relaxation of a system to the state governed by the Fokker-Planck equation and with the termination of the time scales in accord with the phenomena under investigation. A lengthy section concerning the effects of initial correlations shows that they are smoothed out during a time interval of the order of the collision time if certain simple conditions usually met are obtained. The paper concludes by discussing irreversibility and by pointing out that the irreversible nature of the kinetic equation has been introduced by requiring the solution to be nonsecular in the limit of large times. *Sylvan Katz* (Newport Beach, Calif.)

Cheng, Ping 4535

Two-dimensional radiating gas flow by a moment method.

AIAA J. **2** (1964), 1662–1664.

Starting from the radiation transport equation (in terms of the specific intensity) for a gray gas in local thermodynamic equilibrium, the author develops an infinite sequence of moment equations which are closed by assuming isotropy of radiation (Milne-Eddington approximation). The partial differential equation for the first moment (the radiative heat flux) is thus derived. The one-dimensional form has been derived earlier by others and, in fact, the three-dimensional form is noted by S. C. Traugott [Proc. 1963 Heat Transfer and Fluid Mech. Inst. (Calif. Inst. Tech., Pasadena, Calif., 1963), pp. 1–13, Stanford Univ. Press, Stanford, Calif., 1963; MR **29** #5622]. Cheng's development seems to parallel the earlier one of Traugott. The proposed general expansion in the complete set of spherical harmonics is of little value unless anisotropy is "small", in which case the harmonic expansion becomes an asymptotic one. Otherwise no rational truncation scheme is evident. The radiative heat flux equation is then combined with the usual mass, momentum, and energy conservation equations for inviscid flow of a thermally and calorically perfect gas. This system of equations is linearized about some uniform state and specialized to two-dimensional steady and one-dimensional unsteady flow. The application of this formulation to wave propagation and flow over a wavy wall is promised for a later paper.

Abonyi, I. 4536

Basic equations of magnetofluido-dynamics in anisotropic media. (Russian summary)

Acta Phys. Acad. Sci. Hungar. **17** (1964), 91–95.

Zuerst werden die aus den Maxwellschen Differentialgleichungen und den Navier-Stokesschen Gleichungen folgenden bekannten Grundgleichungen der Magnetohydrodynamik explizit angegeben und dann wird die Frage besprochen, wie diese Gleichungen abzuändern sind, wenn das fragliche Medium anisotrop wird, die elektrische und die magnetische Permeabilität (ε und μ) und die Leitfähigkeit σ also zu Tensoren werden. Der Verfasser beruft sich dabei auf die Tatsache, dass dieser Fall tatsächlich auftreten kann, wenn das magnetische Feld recht gross wird, weil dann die Zyklotronbewegung der Elektronen diese Anisotropie verursacht.

Zur tatsächlichen Durchführung der Rechnung werden die zu μ_{ij} und σ_{ij} reziproken Tensoren eingeführt und dann werden alle Grössen durch die mechanischen Variablen p, ρ, und v_i und die Feldgrössen H und B ausgedrückt. Die erhaltenen Resultate werden am Ende der Arbeit zusammengefasst und kritisch besprochen.

Effet des corrélations sur les coefficients de transport d'un plasma. (English summary)

Acad. Roy. Belg. Bull. Cl. Sci. (5) **47** (1961), 245–258.

Authors' summary: "A closed formula is obtained for the long living correlations in an inhomogeneous plasma; it is expressed in terms of the one-particle distribution function. This forms an appropriate starting point for a rigorous theory of transport phenomena in plasmas, including the effect of molecular correlations. An expression is obtained for the thermal conductivity."

Dupree, Thomas H. 4538

Theory of radiation emission and absorption in plasma.

Phys. Fluids **7** (1964), 923–940.

The author gives a consistent treatment of emission and absorption of radiation on the basis of kinetic theory for plasma situations where the collective effects are dominant. For the radiation field this means the low-frequency range that coincides for most plasmas of laboratory or astrophysical origin with the radio frequency spectrum. In this range, the basic radiation mechanisms are Bremsstrahlung and cyclotron radiation; however, due to the collective interaction of the plasma electrons, longitudinal and radiating modes are coupled. General formulas are worked out that cover various coupling possibilities in addition to explicit expressions for Bremsstrahlung and cyclotron radiation.

L. F. Oster (New Haven, Conn.)

Fante, Ronald 4539

Kinetic equations for a plasma including radiation in the presence of an external magnetic field.

Phys. Fluids **7** (1964), 940–948.

The interaction of electromagnetic radiation with a one-component plasma in an external magnetic field is investigated. Canonical position and momentum variables for the radiation field are introduced by replacing the field by a system of oscillators. Following Simon and Harris [Phys. Fluids **3** (1960), 245–254; MR **22** #7320], cluster expansions for both oscillator and particle distribution functions are introduced. A note on the dimensionless expansion parameters of this perturbation solution is appended.

An equation of radiative transfer and a Fokker-Planck

equation are obtained for describing relaxation to equilibrium. As is to be expected, the final expressions are quite cumbersome. The limiting case of vanishing magnetic field is also presented. Time scales for the relaxation process are briefly discussed. The calculation is a lengthy one but is clearly summarized.

G. L. Lamb, Jr. (E. Hartford, Conn.)

Gogosov, V. V. 4540

On the resolution of an arbitrary discontinuity in magnetohydrodynamics.

Prikl. Mat. Meh. **26** (1962), 88–95 (*Russian*); *translated as J. Appl. Math. Mech.* **26** (1962), 118–129.

Riemann's plane problem in a perfectly conducting adiabatic gas is discussed in the presence of a magnetic field which is set normally to the plane of discontinuity at $x=0$ at the instant $t=0$. (The author asserts that the limiting process from the more general case [the author, Prikl. Mat. Meh. **25** (1961), 108–124; MR **27** #5462] is rather complicated.) Possible types of resolution of the initial discontinuity into some combinations of various discontinuities are determined by use of $P-H_y$ diagrams and are shown as domains in the $(\delta u, \delta v)$-plane, where P is the square of pure sound speed divided by initial Alfvén speed, H_y the induced transversal magnetic field and $(\delta u, \delta v)$ is the initial velocity jump across the discontinuity. Six different diagrams are found to be possible for the $(\delta u, \delta v)$-plane depending upon the initial values of P in $x>0$ and $x<0$ referred to in the first case.

Johnson, Eric G., Jr. 4541

Use of the index of refraction as a means for study of plasma configurations.

Phys. Fluids 7 (1964), 1551–1552.

An analysis is given of a laboratory plasma which is in an equilibrium configuration but subject to small perturbations as a result of the action of an external A.C. signal. It is shown on the basis of fairly general assumptions that the off-diagonal elements of the dielectric tensor cannot all vanish. *S. Gartenhaus* (Lafayette, Ind.)

Jukes, J. D. 4542

Gravitational resistive instabilities in plasma with finite Larmor radius.

Phys. Fluids 7 (1964), 52–58.

Author's summary: "The linearized equations of a gravity driven, resistive instability of a plasma supported by a planar, sheared magnetic field are shown to be characterized by a variational principle from which an eigenvalue corresponding to a periodic growth is obtained. The effect of a finite ion Larmor radius is included through off-diagonal terms in the pressure tensor in the momentum fluid equation. When the Larmor radius is zero, a numerical solution for the growth rate is found using a one-parameter trial function which indicates that the correct function maximizes this rate. When the Larmor radius becomes significant, viz., with decreasing wavelength, the instability becomes an overstability with a reduced growth rate becoming proportional to the square root of the ratio of the resistivity to the wavelength. Whilst numerical results are given beyond this transition, the Larmor radius has become comparable with the thickness of an internal resistive layer and the equations cease to be reliable."

H. Weitzner (New York)

Jukes, J. D. 4543

Micro-instabilities in magnetically confined, inhomogeneous plasma.

Phys. Fluids 7 (1964), 1468–1474.

Author's summary: "Plasma with a density gradient supported in a strong, nearly uniform magnetic field is liable to resistive, gravitationally (g-) driven instability and short-wave drift instability. Waves associated with both propagate almost perpendicular to the field lines. Only a low g, and low density plasma are considered, for which these flutelike perturbations remain quasi-electrostatic, so that dispersion relations are readily found. When the magnetic-field lines are sheared, the localized perturbations which arise are treated by a phase-integral approximation and growth rates appear as eigenvalues of certain standard equations. The ions are treated throughout by the Vlasov equation so that fine-scale features such as finite ion Larmor radius a_i and Hall current are correctly included. The results for the resistive, gravitational instability are compared with those based on fluid equations and are valid if the perturbation is not localized within a_i."

Kuehl, Hans H. 4544

The kinetic theory of waves in a warm plasma excited by a current source.

J. Math. and Phys. **43** (1964), 218–226.

The author considers the waves in a warm, homogeneous and unbounded plasma excited by an electric dipole by using Boltzmann's equation. He determines the expression for the electric field and has shown that, except for Landau damping, the hydrodynamic and kinetic theories give the same result for the longitudinal waves for frequencies near the plasma frequency only. However, in the case of transverse waves, the two approaches give identical results for all frequencies greater than plasma frequency. *F. C. Auluck* (Delhi)

Lamb, G. L., Jr.; Burdick, B. 4545

Exact solution of the differential equation for the nondivergent correlation function in a one-component plasma.

Phys. Fluids 7 (1964), 1087–1088.

Frieman and Book [Phys. Fluids **6** (1963), 1700–1706; MR **28** #3821] derived a differential equation for the position-dependent factor in the two-particle equilibrium correlation function for an electron plasma balanced by infinite mass ions. By taking account of the mutual Coulomb force between the two electrons (usually ignored because it is small except when they are very close) they avoided a singularity for the interparticle distance 0, thus achieving a "nondivergent" correlation function for this special plasma.

The present paper refines the work of Frieman and Book by showing that this correlation function can be expressed exactly in terms of the solution of the associated Mathieu equation (with the independent variable t replaced by iz).

Méthode d'étude de la stabilité de certaines solutions de l'équation de Vlasov.

C. R. Acad. Sci. Paris **259** (1964), 1706–1709.

Authors' summary: "On étudie la stabilité de systèmes plasma-champ électromagnétique en négligeant le rayonnement, c'est-à-dire le flux du vecteur de Poynting. Le champ électromagnétique est décrit par les équations de Maxwell et le plasma par l'équation de Vlasov. La méthode consiste à rechercher les perturbations linéaires, qui conservent l'énergie et l'impulsion du système champ-particules."

Lenard, Andrew 4547

On Bogoliubov's kinetic equation for a spatially homogeneous plasma.

Ann. Physics **10** (1960), 390–400.

Author's summary: "An integral equation, proposed by Bogoliubov, to determine the time development of the velocity distribution of a spatially homogeneous plasma is considered. It is shown that the time derivative of the velocity distribution can be expressed explicitly in terms of the distribution itself. The resulting kinetic equation has all the required properties, in particular, it satisfies the $\mathscr{H}$-theorem. By means of an excellent approximation it can be reduced to that derived by Landau."

A similar result has been achieved by R. Balescu [Phys. Fluids **3** (1960), 52–63; MR **23** #B1959].

Matsuura, Kenya 4548

Interaction between plasma oscillation and radiation field. I. Radiation damping of plasma oscillation.

J. Phys. Soc. Japan 18 (1963), 1319–1325.

This paper discusses an interaction between plasma oscillations and the radiation field in a high temperature plasma, free from density and temperature gradients and magnetic fields, but not in thermal equilibrium. For a system of plasmons and photons in thermal equilibrium it is clear that the longitudinal and transverse modes are independent, but for a non-equilibrium system coupling can take place.

A quantum-mechanical treatment is used to derive an expression for the radiation damping of the plasma oscillations; however, this expression is simply the classical limit. This result is then compared (in the case of a classical plasma, $T=10^6$ °K, $n=10^{14}$ particles cm^{-3}) with Landau damping, mode-coupling damping and collision damping for a range of $k\lambda_D$ (k is the wave number, λ_D the Debye length). The radiation damping is non-vanishing for $k\to 0$ and dominates Landau damping for $k\lambda_D \lesssim 1/7$ but is several orders of magnitude smaller than mode-coupling damping over the range of k.

Field correlation functions in a plasma.

Phys. Fluids 7 (1964), 813–815.

Authors' summary: "The correlation function between the electrostatic field at point a and the electrostatic field at point b in a fully ionized hydrogen plasma is computed. The correlation function is shown to be a long-range function of the distance between points a and b. This result has significance in the treatment of transport properties in a plasma." *H. Weitzner* (New York)

Rand, S. 4551

Quantum effects on the conductivity of a dense plasma.

Phys. Fluids 7 (1964), 64–71.

The interaction of a radiation field with the collective modes of a plasma becomes important when the plasma frequency approaches the radiation frequency. The particle interaction must be treated quantum mechanically when electron plasma wave-phonon energies are in the neighborhood of, or greater than, the average random electron energies ($\bar{E}$). Both these conditions are established when optical or infrared radiation interacts with a dense plasma. The values for conductivity and opacity are computed (for the high frequencies) in the limit of a fully ionized high-density plasma. Finally, it is proved that, when the limit of the photon energy is much greater than the average random energy, and when $\omega_p \gg \omega_{\text{rad}}$, then the free-free contribution to the opacity is reduced by a factor of $\bar{E}\omega_{\text{rad}}^2/\hbar\omega_p^4$.

Sanfeld, Albert 4552

Répartition des pressions dans un fluide chargé et polarisé.

Acad. Roy. Belg. Bull. Cl. Sci. (5) **50** (1964), 339–357.

Author's summary: "Ce travail expose quelques modes de calcul de la répartition de la pression dans des couches chargées et polarisées, à température uniforme, où la constante diélectrique dépend de la température, des concentrations des divers constituants et du champ électrique. Une expression très simple a été obtenue pour la couche plane en équilibre mécanique. Pour des couches de forme sphérique, cylindrique ou quelconque, le calcul est théoriquement possible, à condition de connaître la répartition du champ et de la constante diélectrique en tout point. Une méthode thermodynamique permet un calcul approché de la répartition des pressions à l'équilibre de diffusion. Enfin, quelques estimations d'ordres de grandeurs sont données."

Seto, Y. J.; Dougal, Arwin A. 4553

The wave equation and the Green's dyadic for bounded magnetoplasmas.

J. Mathematical Phys. 5 (1964), 1326–1334.

Authors' summary: "In studies of electromagnetic wave propagation and radiation in magnetoplasmas, the wave equation takes the form of a dyadic-vector Helmholtz equation. The investigation here shows that the dyadic-vector Helmholtz equation is solvable by the separation method in four cylindrical coordinate systems. Solutions in the form of complete sets of eigenfunctions are possible when boundary surfaces are present. For problems

involving current sources in the plasma, the Green's dyadics for finite or semifinite domains can be constructed from the complete sets of eigenfunctions which are solutions to the homogeneous equation. The Green's dyadic for infinite domain is also shown to be obtained from that for a semifinite domain through a limiting process."

Tidman, D. A.; Guernsey, R. L.; Montgomery, D. 4554
"Test particle" problem for an equilibrium plasma.
Phys. Fluids 7 (1964), 1089–1091.

The authors derive a Fokker-Planck equation for a "test particle" distribution from the many-species Balescu-Lenard equation. The friction and dispersion coefficients are reduced to simple expressions for fast test particles, and compared with those previously calculated by Rostoker and Rosenbluth [Phys. Fluids **3** (1960), 1–14; MR **22** #4340]. The calculation has the advantages of being much more straightforward than earlier ones, and of yielding a Fokker-Planck equation for which there is no limitation in time and which predicts a relaxation to a Maxwell distribution. *H. Weitzner* (New York)

Trübenbacher, E. 4555
Die Thermodiffusion für ein binäres Gemisch von Gasen aus rauhen Kugeln gleicher Massen und gleicher Durchmesser.
Z. Naturforsch. **17a** (1962), 539–549.

In this doctoral dissertation the Boltzmann equation is formulated for a model of rough spherical molecules in isotropic approximation of the angular velocities by means of corresponding scattering cross-section, and for this the validity of "detailed-balance equation" presented. The thermal diffusion factor for a binary gas mixture of rough spheres is then computed with this scattering cross-section by means of the general formal theory. The derived formulae are used to determine the constants of thermal diffusion and thermal conductivity. While strong similarities in the applied mathematical model yield theoretical agreements with S. Chapman's findings, the great difference between the theoretical and experimental value of the thermal diffusion factor (1:15) makes the application of the chosen mathematical model questionable since even in a D_2 and H_2 gas the molecular behavior strongly deviates from that of a spherical molecule. Many authors expressed doubts lately concerning the validity of the Boltzmann equation, emphasizing the necessity for a deeper analysis of the collision mechanism. The Boltzmann description, even in the formulation of a rough spherical molecule, corresponds to a hypothetical physical situation with many independent random reflections, and the distribution function can be defined only by specifying the collision mechanism. The author also admits that greater accuracy is not to be expected from the "unphysical model of rough spheres". Besides, in a thermal diffusion process the irreversibilities in the collision mechanism cannot be neglected. The problem at hand demands a more sophisticated approach.

Woods, L. C. 4557
On the boundary conditions at an insulating wall for hydromagnetic waves in a cylindrical plasma.
J. Fluid Mech. **18** (1964), 401–408.

The dispersion relation for the propagation of hydrodynamic waves along a magnetized cylindrical plasma falls by a factor of ten as the plasma resistivity tends to zero. This results in the two required boundary conditions at the walls being reduced to a single condition due to the presence of a current sheet. Furthermore, if the ratio of the wave frequency to the ion cyclotron frequency (Ω) is assumed to tend to zero, then the nature of this single boundary condition for the slow hydromagnetic wave depends on the quantity $\sigma^{1/2}\Omega^2$ (where $\Omega^2=\omega^2/\omega_{c_i}^2$). Similarly, if $\Omega\gg 1$, the fast wave is determined by the boundary conditions associated with the limiting value $\Omega\sigma^{-1/2}$. Finally, it is shown that "resistive waves" accompany both fast and slow waves. (These are required in order to satisfy small but finite values of σ^{-1}.) The effects of these waves are studied and their contribution to the wave damping is determined.

Alder, B. J. 4558
Studies in molecular dynamics. III. A mixture of hard spheres.
J. Chem. Phys. **40** (1964), 2724–2730.

Part II (by the author and Wainwright) appeared in same J. **33** (1960), 1439–1451 [MR **22** #6116].

Author's summary: "For an equimolar mixture of hard spheres differing in radius by a factor of 3 it is shown that the numerical method gives the thermodynamic properties within 1% accuracy in the fluid region but generates metastable states at solid densities. The Percus-Yevick theory for mixtures is shown to be as accurate as for pure systems, which makes it plausible that no two-fluid phase region exists for mixtures of spheres. The volume of the mixture is found to be always smaller than the volume of the two pure fluid components, however, at high pressures when a solid and fluid must be mixed to give a fluid mixture, the excess volume is positive. The excess properties are small so that the assumption of ideal mixing (no excess volume) leads to an accurate predication of the properties of hard sphere mixtures. Furthermore, the conclusion can be drawn that the excess properties in mixing ordinary liquids are primarily determined by differences in the attractive potentials rather than solely by the molecular sizes of the pure components."

On variational principles in which the Lagrangian function involves third order derivatives.

Ann. Mat. Pura Appl. (4) **64** (1964), 77–97.

Many of the theories of relativistic particles endowed with spin are based on variational principles whose Lagrangians involve second-order derivatives of the position vector (principles of the second kind). A detailed discussion of such variational problems subject to conditions involving parameter-invariance was given by the reviewer [same Ann. (4) **55** (1961), 77–104; MR **25** #1469], while an entirely new theory of relativistic spin particles based on a variational principle of the third kind (i.e., one whose Lagrangian involves third-order derivatives) was recently suggested by Z. Borelowski [Acta Phys. Polon. **21** (1962), 609–635]. The present paper is devoted to an extension of the above-mentioned parameter-invariant theory to third-order problems. The conditions to be satisfied by the Lagrangian as a result of parameter-invariance are discussed in detail. Further requirements, prompted by physical considerations, are used to narrow down the choice of suitable Lagrangians. One of these leads to a special class of the equations of motion obtained by the reviewer [Ann. Physik (7) **7** (1961), 17–27; MR **22** #10725] from first-order variational principles associated with a conservation of total angular momentum law, while an alternative stipulation gives rise to the equations of motion of Z. Borelowski [loc. cit.]. *H. Rund* (Pretoria)

Remarks on a coordinate transformation to an accelerated frame of reference.

Amer. J. Phys. **32** (1964), 279–285.

A coordinate transformation from an inertial frame $R(x, y, z, t)$ to a non-inertial frame $R'(X, Y, Z, T)$ accelerating along the x-axis was recently derived by H. Lass [same J. **31** (1963), 274–276; MR **26** #7389]. The present paper analyses the assumptions on which the derivation of this transformation is based. The properties, and their mutual implications, involved in Lass's transformation, are studied in great detail. A particularly important implication of these properties is that R' moves with respect to R as a rigid body in the Born sense, and that each point of R' has a constant proper acceleration. *P. S. Florides* (Dublin)

Valqui, Holger 4567

Derivation of the transformation equations in the special theory of relativity. (Spanish)

Univ. Nac. Ingen. Inst. Mat. Puras Apl. Notas Mat. **1** (1962/63), 41–48.

Weinstock, Robert 4568

Derivation of the Lorentz-transformation equations without a linearity assumption.

Amer. J. Phys. **32** (1964), 260–264.

The author derives the Lorentz equations from four

assumptions which are, briefly: (A) Inertial frame β moves at velocity $\mathbf{v}$ relative to inertial frame α along their common xx' axis; α moves at velocity $-\mathbf{v}$ with respect to β; (B) Two lines, each parallel to $\mathbf{v}$ in α, are also parallel lines in β; the distance between them is the same in both frames; (C) At a point where $x'=x$, t and t' are equal; (D) The velocity of light is the same for all reference frames and all directions.

The discussion is based on a thought experiment in which a flash of light is emitted at the origin of α and received at the origin of β. Most of the derivation is a proof that the Lorentz transformation is linear; this proof requires only (A) and (D) and the assumption that the transformation is continuously differentiable. Assumption (B) gives $y=y'$, $z=z'$, and assumption (C) is used to obtain the constant $\gamma=(1-v^2/c^2)^{-1/2}$.

Droz-Vincent, Philippe 4569

Suppression des contraintes du champ de gravitation par l'introduction d'une source vectorielle.

C. R. Acad. Sci. Paris **259** (1964), 515–518.

It is well known [P. G. Bergmann, Phys. Rev. (2) **75** (1949), 680–685; MR **10**, 408] that the Einstein gravitational equations are subject to four constraints, due to the invariance of the field Lagrangian under the group of four-dimensional coordinate transformations.

The author proposes to remove these constraints (and also to destroy the invariance of the Lagrangian) by introducing an "external" vector source, which is given a priori as a function of the coordinates. *A. Peres* (Haifa)

Efinger, Helmut J. 4570

Der kugelsymmetrische Fall einer statischen Ladungsverteilung bei stark komprimierter Materie in der allgemeinen Relativitätstheorie.

Acta Phys. Austriaca **17** (1963/64), 347–350.

The author derives the static, spherically symmetric form of Einstein's field equations for a charged fluid in the presence of an electric field. The equations are integrated under the assumption of an ultra-relativistic equation of state, corresponding to vanishing trace of the energy tensor. This generalizes results found by O. Klein [Ark. Mat. Astronom. Fys. **34A** (1948), no. 19; MR **9**, 627] for the case of no electric field. *W. Israel* (Edmonton, Alta.)

Graiff, Franca 4571

Sull'uso di coordinate armoniche in relatività generale.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 312–320.

The author discusses the advantages of writing various expressions which involve the Christoffel symbols and their derivatives as tensorial expressions in which each term is a tensor by replacing the Christoffel symbols $\{_j{}^i{}_k\}$ by three-index tensors $\rho^i{}_{jk}$ which equal the difference of the Christoffel symbols of the V_4 and an E_4. Thus any special choice of coordinates defined by special values of the $\{_j{}^i{}_k\}$ and their derivatives leads to covariant equations for the $\rho^i{}_{jk}$ satisfied in any frame. As an example, he shows that if the "cartesian" coordinates (x^i) associated with the most general static, spatially spherically symmetric solution of the Einstein field equations are required to be harmonic $(g^{rs}\{_r{}^i{}_s\}'=0,\ i=1,\cdots,4)$, then the metric specializes to that of Schwarzschild.

Klauder, John R. 4572

Linear representation of spinor fields by antisymmetric tensors.

J. Mathematical Phys. **5** (1964), 1204–1214.

Let γ^μ be the four Dirac matrices and $\gamma^{\mu\nu}\equiv\frac{1}{2}(\gamma^\mu\gamma^\nu-\gamma^\nu\gamma^\mu)$; let v be any non-zero spinor for which $\gamma_5 v\neq\pm iv$. An arbitrary spinor field $\psi(x)$ can then be expressed by $\psi(x)=\frac{1}{2}f_{\mu\nu}(x)\gamma^{\mu\nu}v$. This relation provides a linear mapping of antisymmetric tensors $f_{\mu\nu}(x)$ onto spinors $\psi(x)$ for any given v. The mapping involves two classes of transformations (gauges); (1) the class of all $f_{\mu\nu}$ which lead to the same $\psi(x)$ for fixed v, called the c-gauge, and (2) the class of all transformations of $f_{\mu\nu}$ which are induced by transformations of v leaving ψ invariant, $\psi=\frac{1}{2}f_{\mu\nu}{}^F\gamma^{\mu\nu}v_F$, called F-gauges. One can then impose two Lorentz-invariant and gauge-covariant subsidiary conditions which permit tensors to behave like spinors. The Dirac equation is cast into tensorial form. The whole study is then generalized to general coordinate transformations leading to coordinate-dependent Dirac matrices. The F-gauge transformations then require a term in addition to the Christoffel term in the linear connection. A corresponding generalization of the Dirac equation is also proposed.

Komar, Arthur 4573

Commutators on characteristic surfaces.

Phys. Rev. (2) **134** (1964), B1430–B1440.

The author discusses derivation of commutation relations for Klein-Gordon, Maxwell and linearized gravitational fields from a Lagrangian formalism. His reason for this is the suitability of Penrose's scalar ψ [R. Penrose, Ann. Physics **10** (1960), 171–201; MR **22** #6563; Phys. Rev. Lett. **10** (1963), 66–68; MR **26** #7397] for a description of gravitational radiation. In particular, he considers the commutators on null surfaces at infinity, deriving the relations for Bondi's "news function" [Bondi, van der Burg, and Metzner, Proc. Roy. Soc. Ser. A **269** (1962), 21–52; MR **26** #4793]. He considers also the failure of the quantization methods in general relativity and indicates a way in which his approach may remedy the situation at least for asymptotically flat spaces.

v. Krzywoblocki, M. Z. 4574

On the equations of motion of a body with variable mass in the Einstein general theory of relativity.

Acta Phys. Austriaca **17** (1963/64), 159–185.

This work consists of three parts: I, II, III (Parts II and III are reviewed below [#4575, #4576]). It deals with the equations of motion, within the framework of general relativity, of a system of (non-rotating) bodies of which one body, A say, loses mass. The ejection of mass from A gives rise to a reaction force (exhaust force) on A. Consideration of the mass variation of A and the resulting exhaust force on A is what makes the present work different from all previous works on the problem of motion in general relativity.

The method of approach is that of Fock [*The theory of space, time and gravitation*, Pergamon, New York, 1959; MR **21** #7042] and Papapetrou [Proc. Phys. Soc. Sect. A **64** (1951), 57–75; MR **12**, 546; ibid. **64** (1951), 302–310; MR **13**, 695]. All their physical and mathematical assumptions on this problem, namely, (1) slow motion of the bodies (compared with c, the speed of light), (2) weakness of the gravitational field, (3) smallness of the dimensions of the bodies as compared with their mutual separation, (4) the harmonic coordinate condition, (5) the expansion of the metric tensor in powers of $1/c$, are here assumed unaltered. A further assumption made is that the lost mass of the body A, once it has left A, does not influence the gravitational field of the system of bodies. Also, the requirement that the body A loses mass necessitates an energy tensor which is different from the energy tensor of a perfect fluid used by Fock and Papapetrou.

The metric tensor, the energy tensor and the equations of motion are derived up to (and including) the second approximation. When the mass variation of A is set equal to zero, the results reduce to those of Fock and Papapetrou.

Part I reviews the approaches, to the problem of motion, of Einstein and his collaborators, and of Fock and Papapetrou, derives the energy tensor incorporating the mass variation of A, and sets up the field equations ($G_\mu{}^\nu\sqrt{-g}=T_\mu{}^\nu\sqrt{-g}$) and the dynamical equations ($(T_\mu{}^\nu\sqrt{-g})_{|\nu}=0$) of the problem.

v. Krzywoblocki, M. Z. 4575

On the equations of motion of a body with variable mass in the Einstein general theory of relativity. II.

Acta Phys. Austriaca **17** (1963/64), 271–300.

In this second part [see #4574 above for Part I] the energy tensor, the metric tensor and the equations of motion in their first approximation are derived. By comparing the equations of motion in their first approximation with the classical rocket equation (Section 4.2) it is shown that the exhaust force on A depends on the exhaust mass and its exhaust velocity.

Part II concludes with the calculation of the energy tensor and the metric tensor in their second approximation.

P. S. Florides (Dublin)

v. Krzywoblocki, M. Z. 4576

On the equations of motion of a body with variable mass in the Einstein general theory of relativity. III.

Acta Phys. Austriaca **17** (1963/64), 392–413.

In this final part [for Parts I and II, see #4574 and #4575 above] the equations of motion in their second approximation are derived. It is shown that when the mass variation of A is set equal to zero, the equations reduce to those of Fock and Papapetrou. The paper concludes with an extensive bibliography and an appendix where various results of the text are proved.

Mikhail, F. I. 4577

Unified field theory. (Italian summary)

Nuovo Cimento (10) **32** (1964), 886–894.

The author continues the investigation of a unitary field theory proposed earlier by W. H. McCrea and the author [Proc. Roy. Soc. London Ser. A **235** (1956), 11–22; MR **17** #1144]. The structural elements are a tetrad field, along with an asymmetric affine connection so chosen that the tetrad field is covariantly constant. The metric is symmetric and determined by the requirement that the tetrad field be orthonormal. Using methods analogous to those by Einstein and Mayer [S.-B. Preuss. Akad. Wiss. Phys.-Math. Kl. **1930**, 110–120], the author shows that the only spherically symmetric solution of his field equations (all contractions of the Riemann-Christoffel tensor are to vanish) possesses the geometry of Schwarzschild's solution.

P. G. Bergmann (New York)

Penney, R. 4578

Duality invariance and Riemannian geometry.

J. Mathematical Phys. **5** (1964), 1431–1437.

It is the purpose of the paper to show how one is led to field equations relating the electromagnetic field to space-time geometry solely by algebraical considerations based on the symmetry properties of the Maxwell-Einstein field. The underlying hypotheses are the following: (I) Space-time is a Riemannian space V_4; (II) Over V_4 is defined a skew-symmetric tensor $F_{\mu\nu}$ which contains all information concerning the electromagnetic field; (III) The field equations relating the geometry of V_4 to $F_{\mu\nu}$ must be algebraic; (IV) The laws of physics must be either first-order or (linear) second-order differential equations.

The author's starting point is what he calls "the duality invariance" of the Maxwell field, by which is meant the invariance of the field under the transformation

$$\begin{bmatrix} F'_{\mu\nu} \\ {}^*F'_{\mu\nu} \end{bmatrix} = M \begin{bmatrix} F_{\mu\nu} \\ {}^*F_{\mu\nu} \end{bmatrix},$$

where M is a unitary matrix and ${}^*F_{\mu\nu}=\frac{1}{2}\eta_{\mu\nu\lambda\rho}F^{\lambda\rho}$ the dual of $F_{\mu\nu}$ (here $\eta_{\mu\nu\lambda\rho}=-(-g)^{1/2}\epsilon_{\mu\nu\lambda\rho}$ is the permutation tensor). The properties of the tensors $t_\mu{}^\alpha=F_{\mu\nu}F^{\alpha\nu}+{}^*F_{\mu\nu}{}^*F^{\alpha\nu}$ and $T_{\mu\nu\alpha\rho}=F_{\mu\nu}F_{\alpha\rho}+{}^*F_{\mu\nu}{}^*F_{\alpha\rho}$ are studied with particular reference to the right dual ${}^*T_{\mu\nu\alpha\rho}=\frac{1}{2}\eta_{\mu\nu\epsilon\gamma}T^{\epsilon\gamma}{}_{\alpha\rho}$ and the left dual $T^*_{\mu\nu\alpha\rho}=\frac{1}{2}\eta_{\alpha\rho\epsilon\gamma}T_{\mu\nu}{}^{\epsilon\gamma}$. It is found that $T_{\mu\nu\alpha\rho}$ has exactly the same symmetry properties as the curvature tensor $R_{\mu\nu\alpha\rho}$ of V_4. By means of an investigation of all the possibilities resulting from an application of the contraction operations and the dual operation, the above postulates yield the field equations $R_{\mu\nu\alpha\rho}+{}^*R^*_{\mu\nu\alpha\rho}=kT_{\mu\nu\alpha\rho}$. These are found to be reducible to the set of nine equations $R_{\mu\nu}-\frac{1}{4}Rg_{\mu\nu}=-kt_{\mu\nu}$. The relations $F_{\mu\nu,\rho}+F_{\rho\mu,\nu}+F_{\nu\rho,\mu}=0$ are then introduced as an additional gauge condition. To this is adjoined the set of equations ${}^*F^{\mu\nu}{}_{|\mu}=0$ (which are now assumed to hold), which renders the system determinate.

Rylov, Yu. [Rylov, Ju. A.] 4579

Relative gravitational field and conservation laws in general relativity.

Ann. Physik (7) **12** (1963/64), 329–353.

Author's summary: "It is shown that by a description of the gravitational field within the limits of Einstein's theory only a relative gravitational field, i.e., the gravitational field at a point x with respect to one at a point x', is physically essential. A reflection of curved space-time into a continuum of flat spaces $E_{x'}$ depending on coordinates

of an arbitrary point x' is made. The relative gravitational field is described by tensor potentials in terms of the two-metric formalism. The relative gravitational field depends on two points: on a current point x and a base point x'. This allows one to localize the gravitational field without violating the equivalence principle. Integral conservation laws for energy momentum and angular momentum are obtained, the energy-momentum tensor being a true relative tensor, i.e., a tensor depending on two points: x and x'. All values connected with a gravitational field are relative to what is interpreted as the presence of some general relativity in the gravitational field."

Schöpf, Hans-Georg 4580

Allgemeinrelativistische Prinzipien der Kontinuumsmechanik.

Ann. Physik (7) **12** (1963/64), 377–395.

Starting with a comparison between general relativistic field theory and continuum mechanics, so-called conservative systems are considered. These are defined by assuming the existence of an elastic potential Φ and the absence of heat flow. For these systems field equations taking entropy into account are derived from a variational principle which involves variation of the world-lines of the medium. Eckart's interpretation [Phys. Rev. (2) **58** (1940), 919–924] of the energy tensor is used, of which the spatial part (stress tensor) is equated to the derivatives of Φ with respect to the elements of the strain tensor as defined by the reviewer [Proc. Roy. Soc. Ser. A **272** (1963), 44–53; MR **26** #7414]. The entropy balance equation is formulated for non-conservative systems using ideas of Kluitenberg and others [Kluitenberg, Mazur, and de Groot, Physica **19** (1953), 689–704; MR **15**, 490; ibid. **19** (1953), 1079–1094; MR **16**, 185; Kluitenberg and de Groot, ibid. **20** (1954), 199–209; MR **16**, 186; ibid. **21** (1955), 148–168; MR **16**, 1188]. *C. B. Rayner* (Brighton)

Świątak, H. 4582

On the algebraic structure of gravitational fields admitting of 5- and 6-parameter groups of motions.

Acta Phys. Polon. **25** (1964), 161–168.

Résumé de l'auteur: "In this paper the algebraic structure of gravitational fields admitting five- and six-parameter groups of motions is investigated, special note being taken of the gravitational fields produced by electromagnetic fields. Applying the modified criterion of integrability of Killing's equations, relations between the algebraic structure of the energy-momentum tensor and that of Weyl's tensor are derived. These show, in particular, that a zero electromagnetic field produces a gravitational field of type N or O, whereas a non-zero electromagnetic field gives rise to a gravitational field of type D or O. It is proved too that in either case Weyl's tensor and the energy-momentum tensor of the electromagnetic field assume the canonical form simultaneously."

A remark on the theory of general geometrodynamics.

J. Math. Mech. **13** (1964), 547.

This note adds a further result to those obtained by the author in a previous paper [same J. **12** (1963), 831–846; MR **28** #1947]. *G. F. R. Ellis* (Cambridge, England)

Hamoui, Adnan 4584

Sur le théorème de Birkhoff et la solution "radiative" de Petrov.

C. R. Acad. Sci. Paris **258** (1964), 6085–6087.

Birkhoff's theorem states that all spherically symmetric solutions of the equations $R_{ik}=0$ can be transformed into the Schwarzschild solution and are therefore essentially static. According to Petrov [Ž. Èksper. Teoret. Fiz. **44** (1963), 1525–1533; MR **28** #1965], this theorem is true only under certain unnecessarily restrictive assumptions concerning the differentiability of the g_{ik}.

The author refutes the work of Petrov by showing that Birkhoff's theorem is valid if the g_{ik} satisfy the conditions of Lichnerowicz. He shows, moreover, that Petrov's alleged counterexample to Birkhoff's theorem is, in fact, equivalent to the Schwarzschild solution.

W. B. Bonnor (London)

Papapetrou, Achille 4585

Champs gravitationnels à symétrie sphérique avec rayonnement électromagnétique.

C. R. Acad. Sci. Paris **258** (1964), 6081–6084.

The author writes the Schwarzschild field in the form

$$(1)\quad ds^2 = -\left(1+\frac{m}{r}\right)dr^2+\frac{2m}{r}\,dr dt + \left(1-\frac{m}{r}\right)dt^2 - r^2(d\theta^2+\sin^2\theta\, d\phi^2),$$

where m is a constant. He then takes m to be a function of $r-t$,

$$(2)\qquad m = f(r-t),$$

and shows that the metric (1) yields an energy tensor representing an outgoing radial flux of photons. He therefore interprets (1) together with (2) as the gravitational field of a star emitting electromagnetic radiation.

The relation of the solution to those of Synge [Proc. Roy. Irish Acad. Sect. A **59** (1957), 1–13; MR **20** #734] and Israel [Proc. Roy. Soc. London Ser. A **248** (1958), 404–414; MR **21** #4807] is discussed.

Allen, William A.; Knolle, Werner E. 4586
Differential corrections applied to the Izsak equations of artificial satellite motion.
Astronom. J. **69** (1964), 393–401.

Authors' summary: "Differential coefficients are derived for use with the Izsak solution of the Vinti dynamical problem. These coefficients are then applied to a typical problem—the least-squares fit of the Izsak equations to a comparison ephemeris. The comparison ephemeris was generated by numerical integration of the differential equations of motion for a satellite in a force field that includes the J_2, J_3, J_4 and J_{22} terms. The Izsak and Borchers second-order equations were determined to be accurate to eight decimal places for a near-earth satellite of low eccentricity in a Vinti gravitational potential. The Izsak equations constitute an intermediary orbit for the one-body problem of celestial mechanics. The Izsak orbit is compared with another well-known intermediary orbit—the rotating-precessing ellipse representation. The Izsak orbit, specified by only six parameters, is approximately twice as accurate as the moving ellipse orbit which requires eight parameters."

Ural'skaja, V. S. 4591
Polar orbits of artificial celestial bodies. (Russian)
Vestnik Moskov. Univ. Ser. III Fiz. Astronom. **1964**, *no.* 4, 34–44.

Polar orbits of artificial satellites are very useful for establishing the parameters of the tri-axiality of the earth and for finding how to avoid radiation belts. In the earth's potential considered by the author certain terms of second order of smallness with respect to the earth's polar flattening are neglected. This permits solving the problem by quadratures. The author takes into account that the earth is not symmetric with respect to the equator and keeps in the expression for the potential the zonal harmonics of odd order which characterize the asymmetry of the earth with respect to the equator. The author investigates twelve types of polar orbits belonging to three main classes: ballistic orbits which intersect the earth's surface, satellite orbits, and receding orbits. Satellite orbits are investigated in detail. For this case the author obtains closed formulas for the satellite coordinates as functions of an intermediate variable which in turn is time dependent. Since these formulas contain inconvenient elliptic functions, the author expands the satellite coordinates in trigonometric series, where terms of order higher than two with respect to the earth's polar flattening are neglected. The author finds that the earth's asymmetry with respect to the equator does not introduce secular terms in all the satellite coordinates, but causes very considerable periodic disturbances.

Ahmad, H. H. 4593

Perturbations of hyperbolic elements. (Russian)

Vestnik Moskov. Univ. Ser. III Fiz. Astronom. **1964**, *no.* 3, 15–27.

The paper is concerned with the construction of an analytic theory of perturbations for the hyperbolic orbital elements. First the differential equations for the hyperbolic osculating elements are derived by using Lagrange's bracket expressions. Then, following R. A. Ljah [Bjull. Inst. Teoret. Astronom. 7 (1959), 422–440], the expansion of the perturbation function in terms of powers of the ratio of the semi-axes is given for the circular restricted three-body problem. This is done for the inner as well as the outer case, i.e., for $r \lessgtr a$, where r denotes the distance between the perturbed and central bodies and a that between the perturbing and central bodies [cf. also N. B. Elenevskaja, ibid. 6 (1957), 434–465; MR 19, 616].

★Inertial guidance.

University of California Engineering and Physical Sciences Extension Series.

John Wiley & Sons, Inc., New York-London, 1962. xiii + 481 *pp.* $18.50.

A good book in "inertial navigation" has been needed for a long time. Until recently most of the material on inertial navigation has been withheld due to security reasons. With the declassification of some material, an excellent text was organized and born. The book is based upon a collection of notes given originally in an intensive course on inertial guidance at UCLA. These notes have since been extended, edited and compiled in book form.

The book is divided into three main sections. The first section, after a short introduction and historical resumé of inertial navigation, contains a comprehensive discussion of the principal inertial sensing instruments and components of a modern inertial guidance system. The analysis consists of vector analysis notations describing the motion of a system in space. The applied mathematician will immediately recognize the theory as that previously studied in analytical mechanics texts. The main chapters of this section discuss the various aspects of gyros (single and two-degree-of-freedom) and internal sensing accelerometers. A discussion of various problems, namely, vibration, mass unbalance, anisoelasticity and random gyro drift, is given. Each of these errors is expressed in a mathematical form. Chapter IV is concerned with the proper testing of the inertial components. Chapter V is an excellent chapter on "stable platforms", which is considered the heart of the inertial system. The platform is replete with mathematical analysis and relies entirely on feedback control analysis. Unfortunately, non-linear effects creep in and cause instability problems. This is a very fertile area for the applied mathematician to be engaged.

The second section is concerned mainly with the problems of designing and mechanizing inertial navigation systems for cruise vehicles, i.e., vehicles requiring navigational information over long periods of time. Chapter VI discusses guidance kinematics and its relation to the coordinate systems and their respective mathematics. Chapters VII and VIII are excellent contributions to the various errors associated with the platform and means of error rectification. This is extremely important for cruise type vehicles. Chapter IX discusses augmented types of inertial systems, namely, "stellar monitored", "Doppler inertial" and damped systems.

The last section discusses guidance systems for rocket vehicles. This is most important for boost vehicles, namely, IRBM, ICBM, Saturn. The flight is short with respect to the cruise type, but the requirements are demanding and exacting. The various schemes are explained and their interactions with the elastic body effects are discussed ever so lightly. The problem of fuel sloshing is explained briefly, but this is a major problem in large-size boosters. The chapter on error is an applied mathematician's haven. The error determination must be precise since the orbiting of satellites is very exacting.

The book ends with an application of inertial guidance to space missions. Celestial mechanics is the heart of the guidance schemes and contains the well-known Kepler equations, Hohmann transfer between orbits and the discussion of elliptical orbits. The chapter ends with the description of the successful space navigation system for the Ranger spacecraft.

In conclusion, the book is an excellent source of information dealing with both practical aspects and theoretical aspects of inertial navigation systems. Persons interested in the applied mechanics of inertial navigation systems will find a wealth of potential problems as well as a number of mathematical solutions to previous ones. Inertial navigation is dynamic in both methods of analysis and existence. More improvements are necessary for space vehicles of the future. The reviewer believes that the book would be enhanced by further additions on aeroelastic effects (wind shears and gusts acting on the vehicle), fuel sloshing effects and autopilot-structural mode coupling effects. The book does not discuss "Pontryagin's Principle" (optimal control) or adaptive control systems. These are becoming extremely important. Any further revision to the book should include these topics.

H. Saunders (Philadelphia, Pa.)

Finzi, Arrigo 4596

On the validity of Newton's law at a long distance.

Monthly Notices Roy. Astronom. Soc. **127** (1963), 21–30.

The author suggests that at great distances Newton's law of attraction should be changed to

$$F = (Gm_1m_2/\rho^2)(\rho/r)^{3/2}, \qquad r \gg \rho,$$

where ρ is some characteristic length (taken here to be half a kiloparsec). This is given no theoretical basis, but is suggested as an ad hoc hypothesis.

It is shown that it is then possible to resolve certain paradoxes arising from apparent contradictions when some problems are attacked by different methods. The problems considered here include the stability of clusters of galaxies, and the relations between galactic rotation and galactic mass.

On the analytic continuation of a logarithmic potential.

Izv. Akad. Nauk SSSR Ser. Geofiz. **1964**, 105–109 (*Russian*); *translated as Bull.* (*Izv.*) *Acad. Sci. USSR Geophys. Ser.* **1964**, 59–61.

In discussing the interpretation of magnetic and gravimetric anomalies in the case of a two-dimensional problem with the aid of methods based on finding by analytic continuation the singularities of a potential, the authors prove that the location of the sources of the potential (which is the true problem of interpretation) and finding the singularities are not, in general, identical problems because of the multivalued nature of the logarithmic potential. An example illustrates very well this important point.

Ein Verfahren zur unmittelbaren Bestimmung der vertikalen Leitfähigkeitsverteilung im Rahmen der erdmagnetischen Tiefensondierung. (English summary)

Nachr. Akad. Wiss. Göttingen Math.-Phys. Kl. II **1964**, 25–35.

Author's summary: "A method is given by means of which the distribution of electric conductivity with depth can directly be determined from observations of geomagnetic variations on the earth's surface; no assumption of a conductivity-model is needed. The method can be applied if the inducing magnetic fields are two-dimensional and quasi-stationary in a wide frequency domain. In its present state the method is not appropriate to investigate horizontal conductivity anomalies. A few concluding remarks concern the practical use of the formalism."

Strakhov, V. N. [Strahov, V. N.] 4601

The problem of obtaining the best numerical method for the transformation of potential fields. I.

Izv. Akad. Nauk SSSR Ser. Geofiz. **1963**, 1780–1797 (*Russian*); *translated as Bull.* (*Izv.*) *Acad. Sci. USSR Geophys. Ser.* **1963**, 1081–1090.

The special properties of harmonic functions involved in the theory of geological interpretation of gravimetric and magnetic anomaly maps are studied and the basic ideas concerning the best numerical schemes and methods of interpretation are formulated.

Essentially these methods (not yet defined in this first part) will be based on the theory of Fourier transforms and, in particular, on Parseval and translation theorems.

The numerical schemes—to be defined in the following parts of this paper [#4602]—will depend on the depth H (presumably as computed from the mapped potential field) of perturbing masses nearest to the ground, but not on their particular shape.

This new and systematic approach to the problem of interpretation seems to be a very promising one.

E. Kogbetliantz (New York)

Strakhov, V. N. [Strahov, V. N.] 4602

The problem of obtaining the best numerical methods for the transformation of potential fields. II, III.

Izv. Akad. Nauk SSSR Ser. Geofiz. **1964**, 55–67; *ibid.* **1964**, 68–81 (*Russian*); *translated as Bull.* (*Izv.*) *Acad. Sci. USSR Geophys. Ser.* **1964**, 30–35; *ibid.* **1964**, 36–42.

The basic ideas of a new interpretation method formulated by the author in his previous paper [#4601] are developed in detail in these two papers. The first one deals with the two-dimensional problem while the second treats the general three-dimensional case of interpretation.

In both cases the optimum numerical coefficients of the final approximate formula are obtained minimizing either the integral of the square of error (global error) or the upper bound of the maximum error. In the first case the positive definite symmetric matrix of the system of linear equations which determine the said coefficients has positive entries only. In the second case only rough approximations can be obtained.

Neuts, Marcel F. 4603

An inventory model with an optional time lag.

J. Soc. Indust. Appl. Math. **12** (1964), 179–185.

The author investigates a dynamic one-dimensional inventory model with independent, identically distributed demands and known probability density function. Two

types of replenishment, at equally spaced times, are available: (1) with immediate delivery and unitary cost k; (2) with one period lag in supply and unitary cost l. The cost of storage is a convex increasing and twice differentiable function of the stock in store, the penalty is proportional to the under-supply, and no other costs or revenues are considered. If x denotes the initial stock, $y-x$ the amount ordered in conditions (1), and u the quantity ordered in conditions (2), it is shown that the reordering policy which minimizes the total discounted cost of a process of unbounded duration is the following:

$$\begin{aligned} y &= x^*, & u &= u^*, & &\text{for } 0 \leq x \leq x^*, \\ y &= x, & u &= \bar{u}(x), & &\text{for } x^* \leq x \leq \bar{x}, \\ y &= x, & u &= 0, & &\text{for } x \geq \bar{x}, \end{aligned}$$

in which $\bar{u}(x)$ is non-negative, continuous and monotone decreasing in x and x^*, $\bar{x}$ are critical levels of the stock. Some degenerate cases are mentioned. For instance, when $l \geq k$, $u^* = 0$ and $x^* = \bar{x}$. The proof is by induction using a sequence $\{f_n(x)\}$ of successive approximations to $f(x)$, the minimum cost of an infinite process starting with x. This sequence is monotone because its first element is obtained by an approximation in the policy space. The arguments are similar to those of R. Bellman [*Dynamic Programming*, pp. 159–164, Princeton Univ. Press, Princeton, N.J., 1957; MR **19**, 820] and S. Karlin [*Studies in the mathematical theory of inventory and production*, Stanford Univ. Press, Stanford, Calif., 1958; MR **20** #767], which are given as references. *B. Bereanu* (Bucharest)

Slagle, James R. 4604

An efficient algorithm for finding certain minimum-cost procedures for making binary decisions.

J. Assoc. Comput. Mach. **11** (1964), 253–264.

A procedure, in this paper, is a method for making a true-false decision based on the outcome of a sequence of elementary binary tests. These tests are represented by random variables x having probability p of being true and $1-p$ of being false. With each test x there is associated a cost c. A procedure over a finite set of tests X is defined inductively on the cardinality of X. A procedure over 0 tests is true or false. A procedure over $n > 0$ tests is a triple $[x, P_0, P_1]$, where $x \in X$ and P_0, P_1 are procedures over subsets of $X - \{x\}$. The value of a procedure is likewise defined inductively. The value of a procedure over 0 tests is the procedure itself, i.e., true or false. The value of $[x, P_0, P_1]$ is defined as the value of P_0 if x is true and P_1 if x is false. Also the average, or expected, cost of a procedure is defined by $c(\text{true}) = c(\text{false}) = 0$

$$c([x, P_0, P_1]) = c + pc(P_0) + (1-p)c(P_1).$$

The general problem is, given a procedure P, to efficiently find a procedure P' of least average cost such that the value of P is the same as the value of P'. In general, a solution can be found by exhaustive search, so that the essential difficulty is to find an efficient method for solution. The author develops such a method for certain restricted classes of procedures, and shows by illustration how his results can be used in the more general case. The presentation is highly readable, beginning with examples from computer programming, geometry and personnel selection. *L. Hodes* (Yorktown Heights, N.Y.)

Programme de risque minimal en programmation linéaire stochastique.

C. R. Acad. Sci. Paris **259** (1964), 981–983.

It is unfortunate that access to Western literature is still so difficult in some parts of Europe. The results are a very special instance of those of the reviewer and W. W. Cooper [Operations Res. **11** (1963), 18–39; MR **27** #3448]. Specifically, the author treats the P-model with zero-order decision rule and no chance-constraints. *A. Charnes* (Evanston, Ill.)

Hanson, M. A. 4607

Duality and self-duality in mathematical programming.

J. Soc. Indust. Appl. Math. **12** (1964), 446–449.

A scalar function $\varphi(x)$ is functionally convex over a set $S \subset E_n$ if for all $x_1, x_2 \in S$, $\varphi(x_1) < \varphi(x_2)$ implies

$$\varphi[\theta x_1 + (1-\theta)x_2] < \varphi(x_2)$$

for all values of θ in the open interval $(0, 1)$.

The author establishes the following duality theorem: If $\varphi(x)$ is a differentiable scalar functionally convex function of the n-vector x, if $f(x)$ is a differentiable m-dimensional functionally concave function, and if x_0 minimizes $\varphi(x)$ over the set $S = \{x : f(x) \geq 0\}$, then there exists an m-vector $v_0 \geq 0$ such that (x_0, v_0) maximizes $\chi(x, v) \equiv \varphi(x) - v'f(x)$ over the set $W = \{(x, v) : \nabla\chi = 0, v \geq 0\}$; and the minimal value $\varphi(x_0)$ of the primal is equal to the maximal value $\chi(x_0, v_0)$ of the dual.

A self-dual convex programming problem is one whose dual is equivalent to it. The following is a paraphrase of the author's self-duality theorem. Let $f: R^n \to R^n$ be a concave mapping and suppose $\varphi(x) = x'f(x)$ is convex on the set $T = \{x : f(x) \geq 0, x \geq 0\}$. If x_0 minimizes $\varphi(x)$ over T, then the problem is self-dual, $\varphi(x_0) = 0$, and x_0 is an extreme point of T. *R. W. Cottle* (Holmdel, N.J.)

Bondareva, O. N. 4608

Some applications of the methods of linear programming to the theory of cooperative games. (Russian)

Problemy Kibernet. No. 10 (1963), 119–139.

The methods and results involve linear inequalities but not extrema. The main result is a distinct improvement of Gillies' theorem [*Contributions to the theory of games*, Vol. IV, pp. 47–85, Princeton Univ. Press, Princeton, N.J., 1959; MR **21** #4850] that a positive fraction of all games have unique solutions. There are a number of other results on necessary and/or sufficient conditions for

existence and nature of cores or k-quotas, and for a 1-dimensional core to be a solution. Systematic and effective use is made of the (finite) set of all expressions of $(1, 1, \cdots, 1)$ as a non-negative combination of independent 0-1 vectors. *J. R. Isbell* (New Orleans, La.)

★Reliable computation in the presence of noise.

The M.I.T. Press, Cambridge, Mass., 1963. xiv + 96 *pp.* $5.00.

Ever since von Neumann's fundamental study of the problem of the construction of reliable automata from unreliable components [von Neumann, *Automata studies*, pp. 43–98, Princeton Univ. Press, Princeton, N.J., 1956; MR **17**, 1040], a way to define computational capacity and to generalize Shannon's fundamental theorem for information transmission in the presence of noise to information processing in the presence of noise has been sought. A solution is presented in this monograph. It is a natural generalization that reduces to Shannon's result in the trivial case of transmission with no processing, and to von Neumann's system in the case in which the processing is limited to a single automaton. The method is based on the use of an error-correcting code with k information symbols applied to k copies of the automation which are not necessarily processing the same information. The probability of error can be made to approach zero by increasing the length of the code in the redundant automaton. The percentage of redundant logic modules is

essentially the percentage redundancy of the code. However, the complexity of the modules increases as the code length increases. The result appears, therefore, to be of considerable theoretical interest but presently not of practical value. *W. W. Peterson* (Honolulu, Hawaii)

Signal detection in a pulse flow. (Russian. Armenian summary)

Akad. Nauk Armjan. SSR Dokl. **38** (1964), 71–76.

For the signal detection in a pulse flow one considers the stationary flow $\Pi = S + N$, where S is the signal flow and N the noise flow, when the moments $t_1, t_2, \cdots, t_n \in (0, t)$ at which the pulses of Π appear are known; using the statistical properties of S and N we can obtain the distribution of the pulses of Π in S and N.

P. Constantinescu (Bucharest)

Jelinek, Frederick 4615

Coding for and decomposition of two-way channels.

IEEE Trans. Information Theory **IT-10** (1964), 5–17.

This paper summarizes a study of two-way discrete memoryless channels. The regions of possible rates of forward and reverse transmission are discussed and investigated. Also, it is found that under rather general conditions a two-way discrete memoryless channel is equivalent to a pair of oppositely oriented interconnected memoryless one-way channels connected in cascade to special channels that are noiseless whenever the signal transmitted in the opposite direction is an appropriate one. In particular, if the transition probabilities are symmetrical, the nature of the decomposition suggests that maximum forward transmission rate for a fixed reverse rate occurs with sources of independent symbols.

W. W. Peterson (Honolulu, Hawaii)

Arimoto, Suguru 4616

On a non-binary error-correcting code.

Information Processing in Japan **2** (1962), 22–23.

Let p be a prime number, $p > n$, and let T be the $n \times 2e$ matrix with ith row $(1, i, i^2, \cdots, i^{2e-1})$, $i = 1, \cdots, n$, with entries from GF(p). The author's code is the null space of T. It is an $(n, n-2e)$ code over GF(p) with minimum distance $d = 2e + 1$. Thus it is optimal with respect to the bound $d \leq n - k' + 1$ for linear (n, k') codes.

To decode, let X be sent and Y received. The error-vector is then $Y - X = A$. Let $C = (c_0, c_1, \cdots, c_{2e-1})$ denote $AT = YT$. By looking at the $i \times i$ matrix $C^{(i)}$ whose jth row is $c_j, c_{j+1}, \cdots, c_{j+i-1}$ $(j = 0, 1, \cdots, i-1)$, the author can prove that if the Hamming weight k of A is at most e, then $\det C^{(i)} \neq 0$ for $i \leq k$ and $\det C^{(i)} = 0$ for $i > k$. He can then determine the values $n_1, \cdots, n_k$ (considered in GF(p)) such that $A = (a_0, \cdots, a_{n-1})$ has $a_{n_i} \neq 0$ as the roots of a polynomial over GF(p) of degree k which is closely related to $C^{(k)}$. At this point he can solve k linear equations, say $\sum a_{n_i} n_i^{\,j} = c_j$, $0 \leq j < k$, arising from $AT = C$, for the k unknown coordinates of A. The author concludes with: "The error-correcting method is systematic and easily programmed for a digital computer and requires a small storage capacity."

Misprint: For $C^{(i)}$, use the definition in this review.

This paper is stated to have first appeared in Japanese in the Journal of the Information Processing Society of Japan **2** (1961), no. 6, 320–325. The present short version contains no proofs, but in a letter solicited by the reviewer the author gives nice proofs of his results. This review contains the substance of the paper.

Whether or not the decoding procedure is as simple as the author claims, the codes he has constructed are of theoretical interest and might well repay further study.

Metzner, John J. 4620

Burst-error correction for randomly-chosen binary group codes.

IEEE Trans. Information Theory **IT-9** (1963), 281–285.

A lower bound is found for the fraction of codes of a given length that are capable of correcting all possible burst errors up to a given length. In the cases where this fraction is not too small, a burst-error-correcting code could be found with high probability by randomly choosing several

codes and examining them. A decoding procedure that could be used with such a code is described.

W. W. Peterson (Honolulu, Hawaii)

Leont'ev, V. K. 4621

On a problem of close-packed codes. (Russian)

Diskret. Analiz. *No.* 2 (1964), 56–58.

In the paper by H. S. Shapiro and D. L. Slotnick [IBM J. Res. Develop. **3** (1959), 25–34; MR **20** #5092] it has been shown that if a close-packed $(n, 2l+1)$-code exists and l is of the form $4r+1$, then $(n+1)$ is a divisor of $l!$.

In the note under review a result is obtained for the more general case of an odd l, which states that in this case $(n+1) < l!B \ln l$, where B is the largest odd divisor of $l!$.

Also it is shown that for values of n greater than some number x_0 (whose existence depends upon a particular factorization of the polynomial $l!(1+C_x^1+\cdots+C_x^l)=\varphi(x)$ and whose definition, given in terms of the divisors of and the coefficients of polynomials arising from this specific factorization, is too involved to be quoted in a short review) no close-packed $(n, 2l+1)$-code exists.

No numerical examples are given.

Varšamov, R. R. 4622

On some singularities of linear codes which correct non-symmetric errors. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 546–548.

One considers the non-symmetric channels for which the probability of the passage $1 \to 0$ is essentially less than for $0 \to 1$ or conversely. If we have the codes $x=(x_1, \cdots, x_n)$ of length n we propose to find M codes stable with respect with r non-symmetric errors. We obtain the necessary and sufficient condition for this and interesting evaluations.

P. Constantinescu (Bucharest)

Wolf, J. K.; Elspas, B. 4623

Error-locating codes—a new concept in error control.

IEEE Trans. Information Theory **IT-9** (1963), 113–117.

Authors' summary: "A new coding technique is proposed lying midway between error-detection and error-correction coding. The block of received digits is regarded as subdivided into mutually exclusive sub-blocks. Errors occurring within particular sub-blocks are detected at the receiver and, in addition, the receiver is able to determine, by using the code redundancy, which particular sub-blocks contain errors. Such error-locating codes permit the location of digit errors to within a sub-block of the received message block without, in general, permitting the precise determination of erroneous digit positions. Two families of such codes are described, both of them limited to locating a single erroneous sub-block. One family permits the detection of up to $t-1$ errors in any one sub-block of length t. The second family locates up to two errors per sub-block, but is generally more efficient in its use of redundancy than the first family. Upper and lower bounds are given for the number of check digits required with any error-locating code. Codes meeting the lower bound exactly are termed optimum error-locating codes. All the codes of the second family, as well as some isolated examples of $t-1$ error-locating codes are optimum in this sense. The amount of redundancy required for such codes does not appear excessive and error location may provide an attractive alternative to conventional error detection in decision feedback communications."

On equivalent and similar grammars of ALGOL-like languages. (Preliminary communication)

Comment. Math. Univ. Carolinae **5** (1964), 93–95.

This brief note considers ways to produce a new grammar from a context-free grammar $G=(T, N, R, S)$ by two operations called extension and reduction, which are defined in terms of certain conditions imposed on the symbols of T and N and the rules of R. The author calls two grammars strongly similar or weakly similar if they have extensions or reductions, respectively, which are equivalent, i.e., if they can be mapped homomorphically onto the same grammar. An example is given to illustrate the theorem that strong similarity implies weak similarity, but not conversely.

A control system with doubling control devices in the presence of dry friction. (Russian. English summary)

Vestnik Moskov. Univ. Ser. I Mat. Meh. **1964**, *no.* **3**, 75–86.

Der Verfasser betrachtet ein Regelungssystem mit zwei Stellgliedern, in denen trockene Reibung vorhanden sei; diese werden eingeführt, um in der Arbeitsweise des Systems eine größere Zuverlässigkeit zu gewährleisten. Die zugrundeliegenden Differentialgleichungen lauten:

$$T D^2\varphi + q\rho + r\delta = \chi(t),$$

$$(VD^2+\tau D+n_1)\rho - s(\sigma D+1)\varphi = -k\,\mathrm{sgn}(D\rho),$$

$$(VD^2+\tau D+n_2)\delta - s(\sigma D+1)\varphi = -k\,\mathrm{sgn}(D\delta);$$

hierbei ist φ die Koordinate der Regelstrecke, $\chi(t)$ die Fremderregung, φ und δ sind die Koordinaten der Stellglieder; die Koeffizienten werden als positiv vorausgesetzt. Zuerst untersucht Verfasser das zugehörige lineare System ($k=0$), vor allem in einigen Sonderfällen, wo periodische Regime auftreten, und zieht sodann die nichtlinearen Glieder in Betracht, indem er sich auf Näherungsrechnungen stützt. Diese sollen den Einfluß der Nichtlinearität auf die möglichen freien Schwingungen sowie die Abhängigkeit der Stabilitätseigenschaft von verschiedenen Systemparametern klären. Einige Beispiele werden angeführt. *R. Reissig* (Berlin)

Synthesis of control systems seeking extrema. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 1156–1161.

Author's summary: "A method is presented for designing high performance extremum-seeking regulators. The method is based on injecting test signals—or alternately reversing the polarity of the input—and measuring the resultant discontinuities in an appropriate derivative of the system's output. Examples are given, and also a sample of analog computer results."

Imaz, C.; Vorel, Z. 4630

On domains of controllability of proper and normal systems.

Bol. Soc. Mat. Mexicana (2) 8 (1963), 79–88.

Consider the linear control system (1) $\dot{x}(t)=Ax(t)+Bu(t)$, $x(0)=0$, A, B constant matrices ($n\times n$ and $n\times s$, respectively). Define Ω as the set of measurable control functions u with components bounded in absolute value by one; $S_T\subset E^n$ as the set of points attainable at time T by solutions of (1) with $u\in\Omega$; $\mathscr{A}_T=e^{-AT}S_T$. For (1) normal it is known [LaSalle, *Contributions to the theory of nonlinear oscillations*, Vol. V, pp. 1–24, Princeton Univ. Press, Princeton, N.J., 1960; MR **26** #2704] that if η belongs to the unit $(n-1)$-sphere, $u(t,\eta)\equiv\operatorname{sgn}[\eta' e^{-At}B]$, then $x_\eta=\int_0^T e^{-At}Bu(t,\eta)\,dt$ belongs to the frontier of $\mathscr{A}_T(\operatorname{Fr}\mathscr{A}_T)$. The authors show that this map $\eta\to x_\eta$ is continuous. This is then used to obtain an approximation to $\operatorname{Fr}\mathscr{A}_T$ by considering a polyhedron P_k generated by $x_{\eta_1},\cdots,x_{\eta_k}$. It is shown that if $\{\eta_k\}$ is dense on the unit sphere, then the closure of $\bigcup_{k=1}^\infty P_k$ is $\mathscr{A}_T$.

The main theorem then characterizes S_T as being essentially a linear map of a set $\mathscr{A}_\infty$ which is independent of T. Specifically, with appropriate conditions on (1), the main theorem states that there exist convex compact sets $\tilde{\mathscr{A}}_T$, $\mathscr{A}_\infty$ symmetrical with respect to the origin and containing a neighborhood of the origin, with $\mathscr{A}_\infty$ independent of T and the Hausdorff distance between $\tilde{\mathscr{A}}_T$, $\mathscr{A}_\infty\to 0$ as $T\to\infty$, such that $x\in\operatorname{Fr}S_T$ if and only if $x=e^{DT}D_T\omega$, $\omega\in\operatorname{Fr}\tilde{\mathscr{A}}_T$, where D is the Jordan matrix similar to A and D_T is a diagonal matrix whose elements are natural powers of T. It is also shown that $\mathscr{A}_\infty$ depends on at most several rows of B.

On the multi-invariance of combined non-linear automatic systems. (Ukrainian)

Avtomatika **1964**, *no.* 4, 87–88.

A set of non-linear difference equations describing automatic control systems is studied. Necessary conditions are given for the simultaneous invariance of certain quantities in such systems.

H. P. Thielman (Alexandria, Va.)

Gabasov, R.; Kirillova, F. M. 4632

The solution of certain problems in the theory of optimal processes. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 1058–1066.

Consider the differential equation

$$(1)\qquad dx/dt=A(t)x+B(t)u(t),$$

where $A(t)$, $B(t)$ are real n-by-n and n-by-m matrices, respectively, $t\in[0,T]$, and $u(t)$ belongs to some linear normed space U of m-vectors (controls). Given $\rho>0$ and two compact, convex sets C_0, C_1 of the euclidean n-space E^n, it is required to find a $u\in U$, and correspondingly a solution $x(t;u)$ of (1) such that (2) $|u|_U\leq\rho$, $x(0;u)\in C_0$, $x(T;u)\in C_1$. Describing C_0 and C_1 in terms of their distance functions, it is also required to find min diam C_0, or min diam C_1, such that (2) hold. The problem is dealt with by using an inequality involving the dual space $(E^n)^*$; this is an extension of similar inequalities by W. T. Reid [Duke Math. J. **29** (1962), 591–606; MR **27** #424] when C_0 and C_1 are single-point sets, and by H. A. Antosiewicz [Arch. Rational Mech. Anal. **12** (1963), 313–324; MR **26** #4017] when C_0 is a single-point set and C_1 is a sphere. The inequality is obtained by Antosiewicz's approach, i.e., by means of the strict separation theorem for convex sets in E^n. (However, the assumptions on the nature of the space U should be made more precise in order to conclude that the set $\alpha(L)$ on page 1064 is closed. The same remark applies to the set $\alpha(L,\Delta)$ on page 1065.) Some variants, as well as a problem of tracking, are also dealt with along the same lines. *R. Conti* (Florence)

Un metodo per la soluzione dei problemi di ottimo nei processi controllati con tempi morti.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 279–298.

Among the generalizations of optimal control problems solved by Pontryagin's maximum principle, the following, which seems to be important in some applications, is solved here. Let (1) $\dot{x}=f(x,u,v)$ be the differential equation with x, u, v vectors of dimensions n, r and s, respectively. u is subjected to taking values in a compact set $U\subset R^r$. The components v_i of v are assumed to take only the values $\pm V_i$, except when they change from $+V_i$ to $-V_i$ or vice versa, in which case $v_i=0$ during a

"dead time" of length Δt (condition (*)). In order to take condition (*) into account, the following expanded system is posed: (2) $\dot{x}_i = f_i(x, u, v)$ $(i = 1, 2, \cdots, n)$; and $\dot{y}_i = w_i$, $(y_i^2 - V_i^2)(w_i^2 - W_i^2) = 0$, $(y_i - v_i)(w_i^2 - W_i^2) = 0$, $v_i w_i = 0$, $i = 1, 2, \cdots, s$. Here the y_i are auxiliary state variables such that $y_i = v_i = \pm V_i$ except for the "dead time" Δt, when $v_i = 0$. The constants $W_i = 2V_i/t$ assure that the duration of this commuting time from $+V_i$ to $-V_i$ (or vice versa) is Δt.

The last three equations are algebraic constraints and the standard method of Lagrange's multipliers is applied, together with Pontryagin's principle. The obtained result is the following: defining ψ, H by $\dot{\psi} = -\psi \cdot f_x$, $H = \psi \cdot f$, the optimal solution satisfies (3) $M(\psi, x) = \sup H(\psi, x, u, v) =$ const, $u \in U$, $v_i = \pm V_i$ $(i = 1, 2, \cdots, s)$, $M(t) = H(t)$ or (in the dead time intervals) (3′) $M'(\psi, x) = \sup H(\psi, x, u, v) =$ const $\leqq M$, $u \in U$, $v_i = \pm V_i$ $(i \neq k)$, $v_k = 0$, $M'(t) = H(t)$.

The switching intervals $(t_k, t_k + \Delta t)$ satisfy the relation

$$\psi(t_k)[f(t_k)_- - f(t_k)_+] = -\psi(t_k + \Delta t)[f(t_k + \Delta t)_- - f(t_k + \Delta t)_+],$$

where the subindices + and − refer to the limit values to the right and left, respectively.

The more general case, when $v \in V$ but the components v_i have a dead time Δt with $v_i = 0$ when changing sign, is also treated like the preceding case. Finally, some applications, especially to the linear case, are given.

In the reviewer's opinion, this result is of importance in many applications, where the dead time may be treated as a small perturbation, i.e., it does not change qualitatively the existence and behaviour of the optimal solution. But mathematically there is some ambiguity in the definition of allowed solutions. In the non-linear case, indeed, the value $v_i = 0$ may give a better performance than either $v_i = \pm V_i$, and this during a time longer than Δt; in this case equation (1) with condition (*) does not apply exactly. System (2), on the other hand, is mathematically satisfying, but (3) and (3′) give merely a necessary condition for optimality, without defining the solution progressively (as Pontryagin's principle does in the now classical case), because H is not maximum in the dead time intervals. *E. O. Roxin* (Baltimore, Md.)

Romiti, Ario 4635

Problemi di ottimo nei processi a più stadi e con parametri di controllo; applicazione ai missili pluristadio.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. 98 (1963/64), 445–464.

This is a discussion of necessary conditions, with reference to the approaches of both Bellman and Pontryagin, for an extremum of $\sum_1^n c_i x_i(T)$, T the terminal time, subject to side-conditions $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}, \mathbf{u}, \mathbf{w}, t)$, in which $\mathbf{w}$ is a parameter, and to various end-conditions. It is shown, as an example, that a necessary condition on thrust altitude $u(t)$, for an idealized planar trajectory of maximal horizontal range for a two-stage missile with fixed mass-function $m(t)$, is $u(t) =$ const. This condition, in an almost everywhere sense, is actually necessary under more general hypotheses and, with the constant properly chosen, such a u furnishes a global maximum for the range problem [the reviewer, Notices Amer. Math. Soc. 9 (1962), 404].

The papers in this volume will be reviewed individually.

Amer, R. A.-R.; Schwarz, H. R. 4639

Contributions to the approximation problem of electrical filters.

Mitt. Inst. Angew. Math. Zürich No. 9 (1964), 99 pp.

Two papers treating the construction of transfer functions for filters with multiple pass bands. The filters are effectively required to have equal maxima of loss in all the pass bands and equal minima of loss in all the stop bands. The problem is solved in terms of the so-called characteristic function of filter theory, an odd or even rational function of frequency.

The part by Amer considers the general problem of a filter with any number of pass bands and stop bands and at arbitrary locations. A special method for the restricted case of one pass band and two stop bands is developed as an eigenvalue problem and is solved by a simple iteration. The more general method involves finding, by linear-programming techniques, the local optimal solutions for all possible pole-zero distributions among the bands; the best local solution is then selected by inspection.

The part by Schwartz deals only with the one-pass-band, two-stop-band case (the general asymmetrical band-pass filter) and follows more closely the classical pattern using hyperelliptic integrals.

Beneš, V. E. 4640
Optimal rearrangeable multistage connecting networks.
Bell System Tech. J. **43** (1964), 1641–1656.

This paper, which continues work by the same author [same J. **43** (1964), 1619–1640; MR **29** #6985] and extends work by C. E. Shannon [ibid. **29** (1950), 343–349; MR **12**, 35], makes good use of elementary number theory (specifically unique factorization into rational primes) in order to design certain classes of rearrangeable connecting networks having a minimum number of cross-points (e.g., relay contacts).

Recall that Shannon's scheme minimizes the number of memory elements used, but, in general, it requires considerable spring load on certain relays. Contrariwise, the author's scheme minimizes the number of cross-points without regard to the number of relays used. The author's principal theorem, which deals with the cost of design, makes crucial use of a number-theoretic function D defined as follows: $D(n)$ is the sum of the prime divisors of n counting repetitions according to their multiplicity.

Hammond, J. L., Jr.; Johnson, R. S. 4642
A review of orthogonal square-wave functions and their application to linear networks.
J. Franklin Inst. **273** (1962), 211–225.

Authors' summary: "Attention is called to the Haar and Walsh functions as being potentially useful in engineering applications. The Walsh functions have a single magnitude with either a positive or negative sign in the range of definition. Each member of the Haar family also has a single magnitude although this magnitude is different for different members of the set. This interesting property makes the Haar and Walsh functions easy to generate as physical signals and enables analog multiplication by these functions to be performed by an appropriate sequence of sign changes.

"In this paper the well-known properties of the Haar and Walsh functions are summarized. Equations are derived which give the output of linear electric networks in terms of Haar and Walsh functions. Expressions relating the Haar and Walsh 'spectra' to the complex Fourier spectrum are presented, and practical applications of the results are suggested. An example illustrating the properties of the Haar and Walsh functions is worked out in detail."

Barzdin', Ja. M. 4643
Universal pulsating elements. (Russian)
Dokl. Akad. Nauk SSSR **157** (1964), 291–294.

The concept of a logical net is here extended to that of a network of pulsating elements. In such a network the connections between elements may change in the course of time and the behavior of each element at time $t+1$ depends on the states of its neighbors at time t. For these circuits, the author solves problems related to the problem of completeness of basis for ordinary logical nets. In particular, the existence of a universal pulsating element is announced. Using blocks built of copies of this element, one can construct a network whose behavior in T units of time simulates that of a given network of pulsating elements in one unit of time.

G. N. Raney (Storrs, Conn.)

Barzdin', Ja. M. 4644
Problems of universality in the theory of growing automata. (Russian)
Dokl. Akad. Nauk SSSR **157** (1964), 542–545.

In the preceding paper [#4643] the author has extended the concept of a logical net to that of a network of pulsating elements (P.E.), where not only the state of an element but also its connections with its neighbors at time $t+1$ are dependent upon the states of its neighbors at time t. In the present article the author goes a step further, considering networks of reproducing elements (R.E.) which, besides being able to change their states and connections, are able to reproduce copies of themselves and to form connections with these copies. The definitions of simulation and universality developed in the paper on networks of P.E. are here extended to networks of R.E. The author announces the existence of an R.E., A^0, which is universal for the class of all R.E. Roughly speaking, this means that for every R.E. A, there is a block B, a network built of copies of A^0, whose inputs, outputs and states correspond in a definite manner with those of A, and a natural number T such that for every network L built of copies of A, there is a network built of copies of B whose changes of state in T units of time correspond to the changes of state which L undergoes in one unit of time. Also considered are generalized reproducing elements (G.R.E.), whose behavior depends upon certain global properties of the net as well as on the states of their neighbors. The existence of a G.R.E. which is universal for the class of all G.R.E. is announced. By declaring some of the elements of a net to be input elements and others to be output elements, one may regard a network as performing a sequence-to-sequence transformation. It is stated that the class of such transformations realized by nets of R.E. coincides with the class of transformations realized by nets of G.R.E.

Krylov, N. V. 4645
Representation of coded regular events in abstract finite automata. (Russian)
Ukrain. Mat. Ž. **16** (1964), 385–389.

Es bezeichne F die freie Halbgruppe mit dem Erzeugendensystem $X=\{x_1, \cdots, x_n\}$ und G die freie Halbgruppe mit dem Erzeugendensystem $Y=\{y_1, \cdots, y_m\}$. Unter einer unitären Kodierung von F in G wird ein Homomorphismus φ von F in G verstanden, bei dem für kein $i\neq j$ das Wort $\varphi(x_j)$ ein Anfang von $\varphi(x_i)$ ist $(i,j=1, \cdots, n)$. Gegeben sei ein System $A_1, \cdots, A_k$ von regulären Ereignissen in F und es sei $\mathfrak{A}$ ein endlicher initialer

Automat mit dem Eingabealphabet X, in dem die Ereignisse $A_1, \cdots, A_k$ durch gewisse Teilmengen $S_1, \cdots, S_k$ der Zustandsmenge dargestellt werden. Es sei ferner $\mathfrak{B}$ ein endlicher initialer Automat mit dem Eingabealphabet Y, in dem die (einelementigen) Ereignisse $\{\varphi(x_1)\}, \cdots, \{\varphi(x_n)\}$ $(\subseteq G)$ durch gewisse Zustände $\alpha_1, \cdots, \alpha_k$ dargestellt werden. Es wird ein endlicher Automat $\mathfrak{A}(\mathfrak{B})$ mit dem Eingabealphabet Y (Superposition von $\mathfrak{A}$ und $\mathfrak{B}$) konstruiert, so daß in $\mathfrak{A}(\mathfrak{B})$ die Ereignisse $\varphi A_1, \cdots, \varphi A_k$ $(\subseteq G)$ durch bestimmte Teilmengen der Zustandsmenge von $\mathfrak{A}(\mathfrak{B})$ dargestellt werden können. Die Konstruktion läßt sich auf den Fall verallgemeinern, daß statt $\{\varphi(x_1)\}, \cdots, \{\varphi(x_n)\}$ beliebige reguläre Ereignisse in G genommen werden, sofern diese in $\mathfrak{B}$ durch paarweise disjunkte Zustandsmengen dargestellt werden (in $\mathfrak{A}(\mathfrak{B})$ wird dann die Superposition von regulären Ereignissen dargestellt (vgl. V. G. Bodnarčuk [dasselbe Ž. **14** (1962), 351–361; MR **26** #3557])). *G. Asser* (Greifswald)

Oehmke, Robert H. 4646

On the structures of an automaton and its input semi-group.

J. Assoc. Comput. Mach. **10** (1963), 521–525.

Let S be a semi-group (input signals). A right-congruence on S is an equivalence such that $x \sim y$ implies $xu \sim yu$. An S-automaton is defined to be a system $(A, /)$, A a set (states), $/$ a function from $A \times S$ into A such that $a/(xy) = (a/x)/y$ for $a \in A$ and $x, y \in S$ (transition operator). There is a natural relationship between S-automata and right-congruences on S. The paper contains some rather trivial remarks concerning these matters.

J. R. Büchi (Columbus, Ohio)

Ritchie, Robert W. 4647

Finite automata and the set of squares.

J. Assoc. Comput. Mach. **10** (1963), 528–531.

It is shown that the set of squares (in binary notation) is not the behavior of any finite automaton. This has previously been found as a biproduct of results on logical systems. The present proof proceeds directly from the definition of finite automata, and hinges on the following lemma: If $y^2 = (2^n - 1)2^l + 1$ with y, n, l positive and $n + l$ even, then $l = n + 2$ and $y = 2^{n+1} - 1$. It is noted that closely related results on Diophantine equations require much more powerful methods.

★Recent Soviet contributions to mathematics. 4656
Edited by J. P. LaSalle and S. Lefschetz.
The Macmillan Co., New York, 1962. viii + 324 *pp.* $8.75.

A disappointingly superficial account of recent Soviet progress in mathematics in view of the promise of the title and the impression given on p. v of the Preface that "... it is not certain that our general scientific community quite realizes the intense scientific activity that prevails in the Soviet Union".

The present volume is an outgrowth of an essay of the editors ["Recent Soviet Contributions to Ordinary Differential Equations and Nonlinear Mechanics", RIAS Tech. Rep. 59-3, 1959], to which have been added similar chapters. Several major fields of Soviet mathematical activity have been neglected, however, and the development of those topics included is very uneven in character. Some sections consist of little more than names and references (which are neither accurate nor orderly), while other parts seem to be intended for someone with no knowledge of mathematics (for example, pp. 59–66 contain nothing concerning Soviet mathematics, but rather an exposition of the inverse-square law of attraction and Newton's second law, together with an attempt to define a derivative and a differential equation). The material on pp. 19–20 concerning the solution of Hilbert's fifth problem is misleading, to cite another example.

Soviet sources have appeared regularly with comprehensive and well-integrated accounts of Soviet developments in all fields (cf., e.g., *Forty years of mathematics in the USSR: 1917–1959* [Fizmatgiz, Moscow, 1959; MR **22** #6672], which contains a bibliography of some 22,000 items by 3600 mathematicians; too infrequently was any real use made of this exhaustive survey); the volume reviewed below [#4657] is one of a series of more recent Soviet accounts of modern developments in mathematics.

A. J. Lohwater (Providence, R.I.)

★Algebra. Topology (1962) [Алгебра. Топология (1962)]. 4657
Itogi Nauki.
Akad. Nauk SSSR Inst. Naučn. Informacii, Moscow, 1963. 224 *pp.* 1.14 *r.*

This volume contains nine articles, largely expository in nature, describing recent developments in Lie groups and homogeneous spaces, semigroups, rings, modules, categories, homotopy theory, differential topology, manifold theory, and graph theory. Each article contains an extensive bibliography of recent work, both Russian and non-Russian; the papers will be given individual reviews.

★Mathematisches Wörterbuch. Mit Einbeziehung der theoretischen Physik. Band I: A–K. Band II: L–Z. 4658
Bearbeitet und herausgegeben unter Mitwirkung zahlreicher Fachgelehrter von Joseph Naas und Hermann Ludwig Schmid.
Akademie-Verlag, Berlin; B. G. Teubner Verlagsgesellschaft, Stuttgart, 1961. *Band I:* xii + 1043 *pp.*; *Band II:* viii + 952 *pp.* *Beide Bände: DM* 450.00.

These two volumes constitute an encyclopedia of most of the terminology of modern mathematics, and give not only definitions (usually with expository accounts) of the terms listed, but also references to the basic literature, whenever needed. Terms or expressions which are used in the definition of a given expression and which are listed elsewhere in the *Wörterbuch* are indicated in the text in a clear but unobtrusive way. At the end of Band II is an extensive list of symbols used in mathematics and theoretical physics. One must know the German expression or word to find its definition, for no word lists in other languages are given; a mathematical dictionary of this type, and not a bilingual or trilingual glossary, was the objective of the editors, who have succeeded in their task.

The *Wörterbuch* is the result of an extensive collaboration of 127 mathematicians, and is a tour de force of editing. The development of mathematics and theoretical physics is such, however, that new editions must be published regularly, as is the case of the *Iwanami mathematical dictionary* (Japanese), revised and enlarged [Iwanami Shoten, Tokyo, 1960; MR **24** #A644], whose first edition was published in 1954 [MR **15**, 1011]. The two dictionaries are similar in structure, the Iwanami dictionary having the disadvantage (for most of us) that its text is in Japanese, although a third edition is in preparation with a parallel English version. It appears that the Iwanami dictionary is considerably more comprehensive, with more current references to the literature, and the material is indexed in English, French and German for the use of Japanese mathematicians. The Iwanami dictionary contains several numerical tables of special functions at the end; however, it seems to the reviewer that the exclusion of such numerical tables from the *Wörterbuch* was a wise decision of its editors, particularly in view of its size.

Misprints are always inevitable in any first edition of a work of this magnitude; the number of these is rather large, although most of them appear in the references to the literature cited at the end of various topics. Typical of those appearing in the text, on the other hand, are the following. "Kloosterman" is spelled correctly on page 926 of Band I, but incorrectly on page 940 of

Band II; "Cesàro" is misspelled on page 926 of Band I, as is "Jaśkowski" on page 833 and "Kerékjártó" on page 730, and "Erdélyi" seems to be misspelled wherever it appears. The bold-face entry "Godefrey Herold Hardy" on page 691 was obviously meant to be "Godfrey Harold Hardy". The nature of these misprints shows, of course, that they are trivial points which detract nothing from the extremely valuable character of the work.

HISTORY AND BIOGRAPHY

Adamo, Marco 4659

Saggi sulla struttura del sistema aritmetico del Regno-Medio egiziano.

Rend. Sem. Fac. Sci. Univ. Cagliari **32** (1962), 101–183.

An Hand von Texten des mittleren Reiches wird der Inhalt der ägyptischen Arithmetik (Zahlbegriff, Rechenoperationen, Bruchrechnung, Maßsysteme) analysiert. Dabei legt der Verfasser seinen Überlegungen eine Gruppe von Axiomen zugrunde, die er—nach einer Übersicht über die Quellen—am Anfang seiner Untersuchungen formuliert (S. 107). Diesen freilich nicht ausgesprochenen Axiomen (S. 152: "taciti postulati") habe der Ägypter seine Regeln und Operationen untergeordnet. Auch die Existenz des logischen Beweises (für kleine Zahlen) und der Begriff der Induktion (für große Zahlen) wird für den Ägypter in Betracht gezogen. *K. Vogel* (Munich)

★Correspondance du P. Marin Mersenne, religieux minime. VIII: Août 1638–Décembre 1639. 4660

Publiée et annotée par Cornelis de Waard. Édition entreprise sur l'initiative de Mme Paul Tannery et continuée par le Centre National de la Recherche Scientifique.

Éditions du Centre National de la Recherche Scientifique, Paris, 1963 [1964]. ix + 787 *pp.* (4 *plates*) 100 *F.*

Dieser Band umfasst die Briefe Nr. 691–803, ferner anhangsweise zahlentheoretische Studien Frenicles und Mersennes Schreiben an G. Naudé über den Magneten. Wir befinden uns kurz nach Erscheinen des *Discours de la méthode* von Descartes (1637) und mitten in den Auseinandersetzungen zwischen Fermat und Descartes um die Extremwert und Tangentenmethode. Mersenne hat den 2. Teil der *Harmonie universelle* (1637) und die *Harmonicon libri* XII (1638) veröffentlicht; gerade entstehen die anonym erscheinenden *Nouvelles pensées de Galilei* (1639), eine Übertragung der *Discorsi e dimostrazioni* (1638). Die einschlägigen Teile der Korrespondenz mit Galilei, Descartes, Fermat, Frenicle und Debeaune sind grösstenteils bekannt; neu treten zahlreiche weitere Stücke der immer mehr in die Breite gehenden Korrespondenz hinzu, die hier erstmals ediert sind. Die wertvollen biographischen, bibliographischen und sachlichen Erläuterungen zu den einzelnen Stücken enthalten eine Fülle bisher unbekannter Einzelheiten; vorzüglich führt das ausgezeichnete Namenregister. *J. E. Hofmann* (Ichenhausen)

Euleri, Leonhardi [Euler, Leonard] 4661

★Commentationes astronomicae ad praecessionem et nutationem pertinentes.

Edited by Leo Courvoisier. Leonhardi Euleri Opera Omnia (Series Secunda, Opera Mechanica et Astronomica, Vol. Tricesimum), Vol. XXX.

Orell Füssli, Zürich, 1964. lxxix + 352 *pp.* *sFr.* 100.00.

Band XXIX (1961) wurde schon in MR **27** #1344 rezensiert. Band XXX *Leonhardi Euleri Opera Omnia* ist für den Astronomen und Mathematiker eine Fundgrube interessanter Untersuchungen. Aus dem Gebiet der sphärischen Astronomie behandelt Euler zwei Aufgaben (lateinisch) sowie eine Anweisung zur Bestimmung der Mittagsgleichung der Sonne (lateinisch), die Berechnung von Neu- und Vollmonden aus Mondfinsternissen (französisch) und einen kurzen Hinweis zum Problem der Sternbedeckungen (französisch). Der Berechnung von Sonnen- und Mondfinsternissen sind drei Arbeiten gewidmet (französisch und lateinisch). Die Ableitung der Mondparallaxe wird für den Fall einer ellipsoidischen Erde diskutiert (französisch); eine weitere Betrachtung beschäftigt sich mit der geozentrischen Monddistanz von einem Fixstern (lateinisch).

Die umfangreichste Arbeit gilt dem Venusdurchgang vom 3. Juni 1769 und der am gleichen Tag stattfindenden totalen Sonnenfinsternis. Euler behandelt hier die Berechnung der Sonnenparallaxe aus Beobachtungen des Venusdurchganges. Im zweiten Teil diskutiert er die Bestimmung der Elemente der Mondbewegung sowie der Längen von Erdorten, von denen aus man Beobachtungen der Sonnenfinsternis anstellte (lateinisch). Der Herausgeber fügte einen Anhang bei (deutsch).

In einer historischen Untersuchung gibt Euler eine Regel an, aus der sich der Beginn irgendeines indischen Jahres berechnen läßt (lateinisch). Die Arbeit wird von O. Neugebauer (Brown University, USA) kommentiert (deutsch). Ein kurzer Brief Eulers an H. W. Clemm (Berlin) über die Bestimmung der Jahreslängen in historischen Zeiten ergänzt diese Betrachtung (lateinisch).

Weitere Arbeiten gelten der Bewegung der Knoten der Planetenbahnen (lateinisch), der Figur und Neigung der Saturnsringe (lateinisch), der Theorie der Fixsternparallaxen (lateinisch), der Vermessung von Meridian-Gradbögen auf der Erde (französisch) und einer Minimumsaufgabe zur Berechnung der kürzesten Dämmerung (französisch). Erwähnt sei noch ein kurzer Brief Eulers über die Sternbilder (deutsch).

Der Band enthält noch vier Arbeiten von Eulers Sohn Johann Albrecht, der ein geometrisches Verfahren zur Bestimmung der Sonnenrotation aus Fleckenbeobachtungen vorschlägt (lateinisch) und auf die Ableitung der Sonnenparallaxe nach den Methoden seines Vaters kurz eingeht (englisch). J. A. Euler stellt ferner recht aufschlußreiche Rechnungen über eine magnetische Sonnenuhr an (deutsch) und behandelt in einer weiteren Arbeit die Figur der Erde (deutsch).

Der Herausgeber Dr. Leo Courvoisier hat es in seiner 69 Seiten langen Einleitung (deutsch) verstanden, die Arbeiten Eulers nicht nur vorzüglich zu erläutern, sondern sie auch einer gründlichen Durchsicht und Korrektur unterzogen. *Rolf Müller* (Degerndorf)

Logic as a mathematical science.
Ann. Japan Assoc. Philos. Sci. **2** (1963), 131–143.

This is the text of an invited address at the annual meeting of the Mathematical Society of Japan at the University of Tokyo on 1 June 1962.

Hasenjaeger, Gisbert 4667
★Einführung in die Grundbegriffe und Probleme der modernen Logik.
Verlag Karl Alber, Freiburg-Munich, 1962. 202 *pp. DM* 21.50.

The author's intention was not to write an elementary textbook of logic but to show the origin of the modern logical notions and to discuss some problems selected among the most typical. The notions and problems with a common origin form a particular aspect of the logic. Every chapter of the book is devoted to another aspect of logic, although different chapters are bound by deductive interconnections.

Chapter I contains the known interpretation of the ancient theory of syllogisms in the modern predicate calculus. In Chapter II the logic is treated as a kind of ontology, i.e., as a theory of being. The world can be described by the catalogue of properties of things and by the catalogues of properties of n-tuples of things. The author refers to some possible philosophical points of view: the realistic, idealistic, fictionalistic, and the skeptic one. The truth tables and the quantifiers are discussed here. In Chapter III, "Logic as Theory of the Language", the standard language of the predicate calculus is described. More general remarks concern the relation of inference and the main semantical notions. The rules of inference are discussed in Chapter IV, "Logic as Methodology". Gentzen's calculus of sequents is the subject of that discussion. "From ... one can derive ..." is written as "$\ldots \vdash_p \ldots$"; hence, "$\vdash_p \ldots$" means "... is provable in the predicate calculus". Thus the different aspects of the calculus of predicates is known to the reader of the first part of the book.

The second part deals with some extensions of the logical language. Its first subjects are the theory of types and some examples of antinomies. The distinction between decidable and undecidable theories is discussed in Chapter VII, "Logic and the Criticism of Reason". The sequences Z of symbols of a theory can be represented as terms t_Z of a fixed symbolism K with a predicate B. A set M of symbol sequences is called regular (as well as enumerable) if a formula A in the symbolism K exists such that for every symbol sequence Z: Z belongs to M if and only if $\vdash_p (\mathbf{A} \to Bt_Z)$. Chapter VIII deals with the logical problems of probability. The author distinguishes between logical, subjective, and statistical probability. Shannon's information measure is defined. The inductive inference is based on incomplete information. The rules of plausible inference of Pólya [*Patterns of plausible reasoning*, Princeton Univ. Press, Princeton N.J., 1954; MR **16**, 556] are quoted.

S. Jaśkowski (Toruń)

Robinson, Abraham 4668
Recent developments in model theory.
Logic, Methodology and Philosophy of Science (*Proc.* 1960 *Internat. Congr.*), *pp.* 60–79. *Stanford Univ. Press, Stanford, Calif.*, 1962.

This article gives a very suggestive survey of some important aspects of model theory of ordinary first-order logic. The "principle of localization" (compactness theorem, completeness theorem) is, of course, given a central role. The well-known results of Łoś and Tarski concerning universal classes are discussed and refined, an interesting interpolation theorem being given in this connection. Lyndon's interpolation theorem is also generalized. The ultraproduct construction is discussed. The author gives a novel proof of the localization principle and the basic property of ultraproducts, using a set-theoretical valuation lemma.

All of this material is given a concrete application by considering all along a theorem of Mal'cev about normal chains of subgroups of a group. The final section of the paper describes some of the author's work about model-completeness, with applications to the theories of algebraically closed fields, real closed fields, and differentially closed fields.

{Important errata: p. 61, beginning of Section 2: the set K_p does not seem to play any role later. p. 62^9, $\sim E(b_\mu, b_\nu) \ldots$. p. 63, third paragraph from bottom: since, according to p. 61, functions may be allowed, it should be assumed that R is closed under all the functions. p. 66^2, "positive sentence Z". p. 66, "Y, Y', Y''" for the three occurrences of "Y".}

Nishimura, Iwao 4670

On a classification of intermediate propositional calculi. (Japanese. English summary)

Sci. Rep. Fac. Lib. Arts Ed. Gifu Univ. Natur. Sci. **2** (1962), 5–9.

Let Σ be the lattice of all the intermediate propositional calculi and $\Pi = \{LP_i(X)\}$ be the lattice of all the propositional calculi $LP_i(X)$ which can be defined by a single basic formula $P_i(X)$ of one variable X. The author defines a homomorphism Σ onto Π by the fact that, for every calculus L in Σ, the strongest basic formula provable in L under the basic formulae $P_i(X)$ can be decided.

K. Ono (Nagoya)

Skolem, Th. 4671

Interpretation of mathematical theories in the first order predicate calculus.

Essays on the foundations of mathematics, pp. 218–225. *Magnes Press, Hebrew Univ., Jerusalem*, 1961.

The author discusses the possibility of developing, in general, ordinary mathematical theories within the first-order predicate calculus (with just constant predicates and finitely many axioms). The author observes that the faith in classical set theory may explain why the distinction between predicate calculi of different orders has been considered essential, asserts that there is no justification for assuming that the notion of subset in axiomatic set theory has Cantor's absolute meaning, and asks if the above distinction is not just a formal one. He recalls that Gilmore [*Summaries of talks presented at the Summer Institute for Symbolic Logic, Cornell Univ.*, 1957, pp. 309–312, second edition, Comm. Res. Div., Inst. Defense Analyses, Princeton, N.J., 1960] has shown how to transform a theory equivalent to the simple theory of types into one formulated in the first-order predicate calculus with axiom schemes and so that provable statements correspond.

The author's method [Dialectica **12** (1958), 443–450; MR **21** #3325] of transforming a theory formulated with axiom schemes (free predicate variables) into one with only ordinary axioms and having at least the same deductive power is very briefly sketched. (That any formula provable in this theory is a transform of a provable formula has not yet been shown.) This sketch is preceded by a description of the steps to be taken so as to properly formulate an ordinary mathematical first-order theory: treatment of the identity relation and elimination of functors in favor of predicates, with an illustration of how the rule allowing for the substitution of individual variables by functors becomes a valid rule of inference. Finally, the author emphasizes the preference for treatment, if possible, within free variable theories.

H. Ribeiro (University Park, Pa.)

Žuravlev, Ju. I. 4672

Set-theoretic methods in a Boolean algebra. (Russian)

Problemy Kibernet. No. 8 (1962), 5–44.

This paper contains a thorough and detailed presentation of the construction of algorithms for computing minimal disjunctive normal forms (dnf's) for Boolean functions. Definitions and basic results are given in the first chapter. The second deals with basic conjunctions that occur in irreducible dnf's. A strengthened form of Quine's algorithm is defined for obtaining the disjunction of all of these from reduced dnf's. A specific algorithm for simplifying dnf's is investigated in Chapter 3, and in Chapter 4 such algorithms are treated as devices for processing information about basic conjunctions that occur in dnf's. In Chapter 5 algorithms of finite order are considered and it is shown that with this class of algorithms the question of passing from a simplified dnf to a dnf whose basic conjunctions each occur in at least one minimal dnf is unsolvable.

E. J. Cogan (Bronxville, N.Y.)

Summersbee, S.; Walters, A. 4673

Programming the functions of formal logic. II. Multi-valued logics.

Notre Dame J. Formal Logic **4** (1963), 293–305.

Part I appeared in same J. **3** (1962), 133–141 [MR **27** #1374]. The authors are interested in programming the functions of multi-valued logic. The method is illustrated by means of a class-scheduling problem. The strategy is to consider the number of lectures given by a particular professor to a particular class to be a function on a multi-valued logic, with the collection of functions subject to conditions imposed by various practical considerations.

B. A. Galler (Ann Arbor, Mich.)

Gnidenko, V. M. 4674

Determination of orders of pre-complete classes in three-valued logic. (Russian)

Problemy Kibernet. No. 8 (1962), 341–346.

A class A of functors in a propositional calculus P is called complete if any functor of this calculus can be expressed by means of functors of A; a class B is pre-complete if it is not complete but if $B \cup \{f\}$, where f is any functor which is not in B, is complete. A class A of functors in P is closed if it is closed with respect to substitution of variables and functors of A for variables. The basis of a class A is a subset $A' \subset A$ such that all other functors in A can be expressed by means of elements of A'. The order of a closed class A is the least non-negative integer p such that there exists a basis A' of A whose functors do not contain more than p arguments.

The author proves that in the three-valued propositional calculus P_3 all pre-complete classes of functors are of order 2. This makes a difference in the case of classical calculus P_2, where this order can be greater than 2.

The proof employs the analysis of pre-complete classes, elaborated by Jablonskiĭ [Trudy Mat. Inst. Steklov. **51** (1958), 5–142; MR **21** #3331].

V. Vučković (Notre Dame, Ind.)

Partis, M. T. 4675

Commutative partially ordered recursive arithmetics.

Math. Scand. **12** (1963), 199–216.

The "numerals" in the commutative partially ordered recursive arithmetic (in short, in V) of the reviewer [Math.

Scand. 7 (1959), 305–320; MR 22 #7939; Bŭlgar. Akad. Nauk. Izv. Mat. Inst. 6 (1962), 15–25; MR 26 #1250] can be conceived, in the case of a finite number n of successors, as n-dimensional "vectors" with the basis $S_1, S_2, \cdots, S_n$ and with non-negative integers as coefficients: every "numeral" in V can be represented in the form $\sum_{i=1}^{n} \xi_i S_i$, where the ξ_i are non-negative integers.

The author applies systematically this point of view and shows that every primitive recursive function f in V can be represented by $f(\sum_{i=1}^{n} \xi_i S_i) = \sum_{i=1}^{n} f_i(\xi_1, \xi_2, \cdots, \xi_n) S_i$, where every f_i is a primitive recursive numerical function uniquely determined by f. The result is proved by establishing an isomorphism between V and an appropriate arithmetic C of n-tuples $(f_1, f_2, \cdots, f_n)$ of primitive recursive numerical functions.

Moreover, the author establishes a deductive isomorphism between V and C in the following sense: from the proof of an equation in V one can obtain the proof of the corresponding equation (between n-tuples) in C, and vice versa. This makes it possible to reduce some involved proofs in V to known proofs in recursive number theory. Also, a very simple investigation of the lattice structure of V is now made possible.

The method of the author (suggested by R. L. Goodstein) seems to provide a powerful tool for the examination of the structure of V.

V. Vučković (Notre Dame, Ind.)

Skordev, D. 4676

Rekursiv vollständige arithmetische Operationen. (Russian summary)

C. R. Acad. Bulgare Sci. 16 (1963), 465–467.

Let α be a binary partial operation on natural numbers whose value for arguments x, y, if it exists, is $x\alpha y$; in iterations of this function parentheses will be omitted according to the rule of association to the left. Then α is called recursively complete when there are natural numbers P, Q, R, S such that the following hold for all natural numbers x, y, z (with existence of either side of the equation entailing that of the other): (I) $P\alpha x = x+1$; (II) $Q\alpha(x+1) = x$; (III) $R\alpha 0\alpha y\alpha z = y$ and $R\alpha(x+1)\alpha y\alpha z = z$; (IV) $S\alpha x\alpha y$ is always defined and $S\alpha x\alpha y\alpha z = x\alpha y\alpha(x\alpha z)$. The principal result of this paper is that if α is such an operation, then every partial recursive function ϕ of n arguments is representable in the form $f\alpha x_1 \alpha x_2 \alpha \cdots \alpha x_n$, where f is a fixed natural number (for fixed ϕ) and $f\alpha x_1 \alpha \cdots \alpha x_{n-1}$ is defined for all $x_1, \cdots, x_{n-1}$. This result is obtained by noticing that the α-operation can be taken as an interpretation of the application operation of combinatory logic; that the combinator S can be interpreted as the number S, and the combinator K as $R\alpha 0$; and then using techniques similar to those which show that all partial recursive numerical functions can be defined in terms of combinators. From the main result it follows that a binary numerical function is a principal function [in the sense of Uspenskiĭ, *Lectures on computable functions* (Russian), Fizmatgiz, Moscow, 1960; MR 22 #12043] for partial recursive functions of one argument just when it is recursively complete and partial recursive; and a recursively complete function is partial recursive just when it has a certain minimal property. It is claimed that these results indicate a possible method for the axiomatization of the theory of partial recursive functions.

H. B. Curry (University Park, Pa.)

Tugué, Tosiyuki 4677

On the partial recursive functions of ordinal numbers.

J. Math. Soc. Japan 16 (1964), 1–31.

In this review functions and functionals take ordinals as values, functions have ordinals, functionals have functions and/or ordinals as arguments. Takeuti and Kino [same J. 14 (1962), 199–232; MR 27 #4747, hereinafter "TK"], developed a theory of primitive recursive (Pr.R) and general recursive functionals; this can be easily extended to include partial recursive functionals (Pa.R). {Reviewer's remark: the definition of Pr.R in TK and the one used by the author are unnecessarily elaborate. More specifically, Pr.R (relative, perhaps, to a class C of functions) is the least class which contains the identity and successor functions, $\lambda x\omega$, $\lambda xy(x \cdot y)$, $\lambda x(1 \dot{-} x)$ (and the functions of C), and which is closed with respect to substitution, the bounded μ-operator, and the recursion schema $\phi(x) = \chi(\phi^x, x)$, where parameters have been omitted, and $\phi^x(y) = \phi(y)$ $(y < x)$, $\phi^x(y) = 0$ $(y \geq x)$. Pa.R is obtained by allowing the unbounded, instead of the bounded, μ-operator.} The author points out that these definitions can be widened (from the "strict" to the "classical" sense) by permitting all constant functions. This distinction has also been drawn by Levy [Notices Amer. Math. Soc. 10 (1963), 286] who refers to "finitarily computable" and "computable" functionals.

The chief aim of the paper under review is to develop an analogue of Kleene's concept of "formally calculable". For this purpose the author adapts work by Machover [Bull. Amer. Math. Soc. 67 (1961), 575–578; MR 26 #17] and sets up an equational calculus in which $\mathrm{Sup}_{z<x} f(z) = y$ may be inferred for appropriate y from the (infinite) set of equations which evaluate f for all ordinals less than x. It is shown that the partial functionals which are formally calculable (from C) in this calculus are exactly those in Pa.R (relative to C). For the strict sense, primitive symbols for ordinals other than 0 and ω must not appear in the defining equations (although, of course, they do appear in the deductions). A Gödel numbering is set up; here the axiom of constructibility is assumed, so that a single ordinal may be used to encode the infinite sequence of ordinals which is necessary to describe a given deduction. In this way a Pr.R analogue of Kleene's T predicate is obtained; this is used to give new proofs of the enumeration and hierarchy theorems of TK. The enumeration of the predicates of a given quantifier form is by natural numbers when the scope of the quantifiers is general recursive in the strict sense; by ordinals if it is general recursive in the classical sense.

{Reviewer's comments: (1) The term "primitive recursive" to describe the class Pr.R is not well-chosen, for Pr.R is a very narrow class. It is not hard to show that if $x < \omega^\omega$ and ϕ is in Pr.R, then $\phi(x) < \omega^\omega$; thus $\lambda x(x^\omega)$ is not in Pr.R. A class which is more properly described as "primitive recursive" is obtained if ϕ^x in the recursion schema is replaced by $\mathrm{sup}_{y<x}\phi(y)$; this does not alter the extent of Pa.R. (2) The assumption of the axiom of constructibility is not necessary. For the sequences of ordinals needed to describe the deduction of a value of a function in Pa.R (or Pa.R relative to C) are themselves general recursive, and are therefore constructible (or constructible from the restrictions to some ordinal of a finite number of functions in C). A similar remark applies to the use of the axiom in TK.}

Péter, Rózsa 4678

Über die Rekursivität der Begriffe der mathematischen Grammatiken. (Russian summary)

Magyar. Tud. Akad. Mat. Kutató Int. Közl. 8 (1963), 213–228.

As an application of her version of the recursive arithmetic of words the author proves that the notion of "grammatically true sentence" in the categorial and phase-structure grammars of Chomsky and Bar-Hillel is primitive recursive in a suitable arithmetic of words, and that the "grammatically true sentences" in the combinatorial grammar of Chomsky form a recursively enumerable set.

The theorems cannot be considered as new (in the first case, a representation by finite automata is possible, and in the second case the recursive enumerability follows by known theorems about combinatorial systems), but the method of proof deserves attention by showing an elegant application of the recursive arithmetic of words to problems of grammatical structures.

Tennenbaum, S. 4679

Degree of unsolvability and the rate of growth of functions.

Proc. Sympos. Math. Theory of Automata (New York, 1962), pp. 71–73. Polytechnic Press of Polytechnic Inst. of Brooklyn, Brooklyn, N.Y., 1963.

A recursively enumerable (r.e.) set M is a "maximal simple" set if, though its complement M' is infinite, every r.e. superset N of M has the property that either $N-M$ or $M'-N$ is finite. The author proves the theorem: If π is the enumerating function of a maximal simple set M and g is any general recursive function, then $\pi(n)>g(n)$ for all $n>k$.

Belnap, N. D., Jr.; Leblanc, H.; Thomason, R. H. 4680

On not strengthening intuitionistic logic.

Notre Dame J. Formal Logic 4 (1963), 313–320.

The paper is concerned with Leblanc's conjecture [Leblanc and Belnap, same J. 3 (1962), 79–82; MR 27 #1367; Belnap and Thomason, ibid. 4 (1963), 39–43; MR 27 #28] to the effect that any rule for "v" which holds in CPC (Gentzen formulation of the classical propositional calculus) also holds in IPC (intuitionistic propositional calculus), from which it follows that the only way of turning standard Gentzen rules of inference for IPC into rules for CPC is to strengthen rules for "$\sim$", "$\supset$", or "$\equiv$". Leblanc's formulation, however, left room for unintended interpretations under which the conjecture proved to be false [cf. Vesley, ibid. 4 (1963), 80; MR 27 #29]. By interpreting a rule for "v" as one with the property that every inference condoned by it can be obtained by substitution from one condoned by it that exhibits no connective but "v" and by interpreting "holding in a system" as derivability of the conclusion of a rule by means of the axioms and primitive rules of the system from the premises, the conjecture thus obtained is shown to be true. A number of alternative interpretations are considered which help to clarify the situation.

Thomas, Ivo 4681

S1° and Brouwerian axioms.

Notre Dame J. Formal Logic 4 (1963), 151–152.

Let B_n be the modal axioms $C'pL^nMp$ (C' for strict implication, L^n for L iterated n times). We say B_n is sufficient if its addition to Feys's $S1°$ yields $S5$. The author proves that (i) no set of axioms of the form B_{2k+1} ($k\geq 0$) is sufficient; (ii) any pair B_1, B_{2k} ($k\geq 1$) is sufficient; (iii) for all m, n ($n>2$), if m and n are co-prime, then B_{m-1}, B_{n-1} are sufficient.

E. J. Lemmon (Claremont, Calif.)

Thomas, Ivo 4682

S1° and generalized S5-axioms.

Notre Dame J. Formal Logic 4 (1963), 153–154.

Let $A_{j,k}$ be the modal axioms $C'M^jpL^kMp$ ($j,k\geq 1$) (C' for strict implication); then $A_{1,1}$ is the usual special $S5$-axiom. We say $A_{j,k}$ is sufficient if its addition to Feys's $S1°$ yields $S5$. The author's main results are: (i) if $j+k$ is odd, $A_{j,k}$ is not sufficient; (ii) if $j=k$, $A_{j,k}$ is sufficient; (iii) if $j=k+2$, $A_{j,k}$ is sufficient.

E. J. Lemmon (Claremont, Calif.)

Thomas, Ivo 4683

A final note on S1° and the Brouwerian axioms.

Notre Dame J. Formal Logic 4 (1963), 231–232.

Let B_n be the modal axioms $LCpL^nMp$ ($n\geq 1$). The author shows that, if any single B_n is added to $T°$ (Feys's $S1°$ together with the rule from α to infer $L\alpha$), the resulting system lacks $CpMp$ and so does not contain T.

E. J. Lemmon (Claremont, Calif.)

Sobociński, Bolesław 4684

A note on modal systems.

Notre Dame J. Formal Logic 4 (1963), 155–157.

It is known that the system $S1°$ of Feys affords the rule: If $\vdash C'M\alpha L\beta$, then $\vdash C'\alpha\beta$. The author states several results concerning interconnexions between various systems which result from $S1°$ or $S2°$ by adding as axioms theses related to this rule (such as $CCMpLqC'pq$, $CCMpLqCpq$).

Zeman, J. Jay 4685

Bases for S4 and S4.2 without added axioms.

Notre Dame J. Formal Logic 4 (1963), 227–230.

Consider the two modal rules: RL1: from $\vdash C\alpha\beta$ to infer $\vdash CL\alpha\beta$; RL2: from $\vdash C\alpha\beta$ to infer $\vdash C\alpha L\beta$, if α is completely modalized. It is known that RL1 and RL2, subjoined to a propositional calculus base with detachment, give $S5$, where α is completely modalized if and only if all occurrences of propositional variables in α lie within the scope of a modal operator. The author shows that the same two rules, subjoined to the same base, give $S4$ and the Dummett-Lemmon $S4.2$ under different interpretations of complete modalization. Thus, for $S4$, we define: α is completely modalized if and only if either $\vdash_{S4}\alpha$ [and α is full modalized in the $S5$ sense] or α is of the form $KL\gamma KL\delta\cdots L\nu$ with $\alpha=L\gamma$ as limiting case. (Actually, the clause in square brackets is redundant.) The $S4.2$ definition of complete modalization requires a third clause: "or of the form $\phi\gamma$, where ϕ is composed of alternating 'L' and 'N', beginning with 'N', and containing at least two 'L's'".

Putnam, Hilary 4686

Uniqueness ordinals in higher constructive number classes.

Essays on the foundations of mathematics, pp. 190–206. *Magnes Press, Hebrew Univ., Jerusalem*, 1961.

The author extends Kleene's definition of H_a to all numbers a in the Kreider-Rogers system C of notations for ordinals. He then extends Spector's uniqueness theorem, which says that the degree of H_a is determined by the ordinal for which a is a notation. The proof consists of an exceedingly complicated application of the recursion theorem. The reviewer feels that the concepts studied here cannot be of much use in further investigations until more manageable ways of dealing with them are developed.

J. R. Shoenfield (Durham, N.C.)

Sedol, Ja. Ja. 4687

The free product of associative calculi with joined subalphabets and certain related questions. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 1034–1037.

An associative calculus $\mathfrak{A}$ in the alphabet A is the semigroup of words in A (under concatenation), together with a finite system of generating relations $\alpha_i \leftrightarrow \beta_i$, $i = 0, 1, \cdots, r$, which defines, in the usual way, the equivalence $\mathfrak{A}: \alpha \amalg \beta$ of words in A. $\mathfrak{A}$ is inversive if to every word α corresponds its inverse α^{-1} such that $\mathfrak{A}: \alpha\alpha^{-1} \amalg \alpha^{-1}\alpha \amalg \Lambda$, where Λ denotes the empty word.

Let $\mathfrak{A}$ and $\mathfrak{B}$ be associative calculi in the alphabets A and B, respectively. Let $C = A \cup B$ and $D = A \cap B$. Suppose that the following two conditions are satisfied. (1) The group condition: If M is a word in letters of D, then there exists an inverse M^{-1} (in letters of D) such that $\mathfrak{A}: MM^{-1} \amalg M^{-1}M \amalg \Lambda$; (2) the isomorphism condition: If M and N are words in the alphabet D, then $\mathfrak{A}: M \amalg N$ implies $\mathfrak{B}: M \amalg N$, and vice versa.

The associative calculus $\mathfrak{C}$ in the alphabet C, obtained from $\mathfrak{A}$ and $\mathfrak{B}$ by the union of their systems of generating relations, is called the free product of $\mathfrak{A}$ and $\mathfrak{B}$ with the common subalphabet D.

The author quotes the following theorems. (1) $\mathfrak{C}: P \amalg Q$ implies $\mathfrak{A}: P \amalg Q$ and (2) $\mathfrak{C}: P \amalg Q$ (P in A, Q in B) implies the existence of Q_1 in A and Q_2 in B such that $\mathfrak{A}: P \amalg Q_1$ and $\mathfrak{B}: Q \amalg Q_2$.

Some more complicated theorems, involving notions of generators, isomorphism, stationary letters, special letters (which cannot be explained here) are quoted, leading to the theorem that one can construct an inversive associative calculus in which the problem of the equivalence is not constructively solvable. This should give a relatively simple constructive proof of Novikov's theorem on the word problem in groups.

The author asserts that the plan of proof of these theorems is borrowed from the paper of J. L. Britton [Ann. of Math. (2) **77** (1963), 16–32; MR **29** #5891].

Wang, Hao 4688

Dominoes and the AEA case of the decision problem.

Proc. Sympos. Math. Theory of Automata (New York, 1962), pp. 23–55. *Polytechnic Press of Polytechnic Inst. of Brooklyn, Brooklyn, N.Y.*, 1963.

Author's introduction: "It has recently been established that the AEA case is unsolvable and forms a reduction class. Several people have looked into possible directions along which the result can be strengthened, using in part earlier methods developed by Büchi for the E and AEA case. There are three different aspects. First, unsolvable AEA subcases such as restrictions on the number of dyadic predicates, on the form of the quantifier-free component, on the complexity of the models (e.g., finite, essentially periodic, etc.). Second, solvable AEA subcases. Third, the detailed structure of the reduction of the general case to the AEA case. A survey of these questions is presented."

A. P. Ershov (Novosibirsk)

Kahr, Andrew S. 4689

Improved reductions of the Entscheidungsproblem to subclasses of AEA formulas.

Proc. Sympos. Math. Theory of Automata (New York, 1962), pp. 57–70. *Polytechnic Press of Polytechnic Inst. of Brooklyn, Brooklyn, N.Y.*, 1963.

The author is interested, for each positive integer k, in whether the class Δ_k of AEA formulas in the predicate calculus involving k dyadic predicates (in addition to monadic predicates) is a reduction class.

The author establishes reduction to the classes Δ_7 and Δ_5, and discusses for some particular cases a procedure of reduction of a class of diagonal-constrained domino problems to formulas in Δ_1.

This is a translation of the author's paper on the abstract theory of automata [Uspehi Mat. Nauk **16** (1961), no. 5 (101), 3–62; MR **25** #1976], together with a translation of a paper on problems of design of automata [Ž. Vyčisl. Mat. i Mat. Fiz. **1** (1961), 371–411].

Red'ko, V. N. 4692

On the commutative closure of events. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1963**, 1156–1159.

Let Y be an event (a set of words) over an alphabet X. By the commutative closure of Y one means the set $\bar{Y}$ of all words which are permutations of words in Y. Let C_X denote the commutative free semigroup over X. There is an obvious correspondence between the commutative closure $\bar{Y}$ and the image of Y in C_X. The author defines a normal commutative event as any set in C_X which may be obtained from finitely many powers of elements in X by finitely many disjunctions and (semigroup) multiplications. His main result is then that the commutative closure $\bar{Y}$ of an event Y is regular (in the sense of Kleene) if and only if the image of Y in C_X is a normal commutative event.

The paper is not self-contained: notably missing is a definition of Medvedev machine (which is invoked to support the proof in one direction).

On the structure of the set of natural numbers. (Spanish)

Collect. Math. **14** (1962), 287–300.

This is a smooth exposition of the construction of the natural numbers and of the definition of the notion of finite set, starting (à la Dedekind) with a one-one function from a set into a proper subset of itself.

E. Mendelson (Flushing, N.Y.)

Piccard, Sophie 4694

Quelques propriétés des constituantes des ensembles de Souslin linéaires et de leurs complémentaires.

Publ. Sém. Géom. Univ. Neuchâtel (1) *Fasc.* 3 (1963), 43–58.

E étant un ensemble souslinien de R, la donnée d'un crible permet de décomposer canoniquement E et son complémentaire E' en une infinité d'ensembles E_α $[E_\alpha']$ deux à deux disjoints et indexés par les nombres ordinaux de deuxième classe. De même, la donnée d'une famille d'ensembles $E_{n_1,\cdots,n_k,k}$ (système déterminant de E) dont E est déduit par l'opération de Souslin, permet une décomposition de même nature que la précédente de E et de E'.

Ceci étant, l'auteur montre: (1) qu'à tout crible élémentaire de E on peut associer un système déterminant régulier tel que les deux décompositions canoniques coïncident; (2) qu'il est possible que les ensembles E_α $[E_\alpha']$ soient mesurables-B et vides lorsque α est de deuxième espèce; (3) que pour un même ensemble E, il peut exister deux cribles C et C^* tels que pour une partie infinie A de $[0, \Omega]$, les E_α et E_α' relatifs à C et d'indices appartenant à A soient vides, tandis que les ensembles de mêmes indices relatifs à C^* ne le soient pas.

A. Revuz (Poitiers)

Erdős, Paul; Tarski, Alfred 4695

On some problems involving inaccessible cardinals.

Essays on the foundations of mathematics, pp. 50–82. *Magnes Press, Hebrew Univ., Jerusalem*, 1961.

The authors investigate six properties of infinite cardinals. λ has the property P_1 if there is a set A of power λ which is simply ordered by a relation $\leq$ such that every subset of A well-ordered by $\leq$ or $\geq$ has power $<\lambda$; the property P_2 if the complete graph on a set of power λ can be divided into two subgraphs, neither of which includes a complete graph on a set of power λ; the property P_3 if, in the set algebra of all subsets of a set of power λ, every λ-complete prime ideal is principal; the property P_4 if there is a λ-complete and λ-distributive Boolean algebra $\mathfrak{B}$ not isomorphic to any λ-complete set algebra; the property Q if, in P_4, $\mathfrak{B}$ is restricted to be λ-generated by λ elements; and the property R if there is a ramification system (tree) $\langle A, \leq\rangle$ of order λ such that for each $\xi<\lambda$, the set of elements of A of order ξ has power $<\lambda$, and every subset of A well-ordered by $\leq$ has power $<\lambda$. It is shown that P_1 implies P_2, P_2 implies P_3, P_3 implies P_4, P_2 implies Q and R implies Q for inaccessible λ, Q implies P_3, and R implies P_3. Furthermore, the properties P_1, P_2, P_3, and P_4 are shown to hold for all accessible cardinals; all the properties fail for ω. Not all of the results mentioned are new; exact references to earlier works are found in the paper, in particular, to an earlier paper of the authors in which most of the results are announced. Additional results are found in the papers of Keisler and Tarski [Fund. Math. **53** (1963/64), 225–308; MR **29** #3385], Hanf [ibid. **53** (1963/64), 325–334; MR **28** #3944], and the reviewer and Scott [ibid. **53** (1963/64), 335–343; MR **29** #3386]. Several open problems are mentioned. The paper is largely self-contained. {Errata: On p. 66 it is erroneously stated that every λ-distributive Boolean algebra is isomorphic to a quotient algebra $\mathfrak{A}/I$, where $\mathfrak{A}$ is a λ-complete set algebra and I is a λ-complete ideal; see the Keisler and Tarski paper [loc. cit.], footnote (9), for the correction.}

COMBINATORIAL ANALYSIS

See also 4914, 5157, 5657.

Abramson, Morton 4696

Explicit expressions for a class of permutation problems.

Canad. Math. Bull. **7** (1964), 345–350.

The author rederives the usual expression for selecting k indistinguishable elements from a linear array of n elements with at most j consecutive elements being selected. This result is then applied to counting the number of selections with the maximum number of consecutive elements being j, computing the probability that the success run of maximum length is j elements long, computing the probability the maximum length of success run is at most j, and counting the number of ways of selecting k elements so that no pair of elements x_i, x_{i+2}, $i=1, 2, \cdots, n-2$, is selected. This last result is applied to computing the probability that in a random permutation none of the $2(n-1)$ events $1\to2$, $2\to1$, $3\to2$, $2\to3$, $\cdots$ occur.

Bernard Harris (Madison, Wis.)

Cheema, M. S. 4697

Vector partitions and combinatorial identities.

Math. Comp. **18** (1964), 414–420.

Let S be a given set of vectors (x, y) whose components are non-negative integers. Let $p(m, n\,|\,S)$ be the number of partitions $(m, n)=\sum (x_i, y_i)$, where the parts (x_i, y_i) are all in S. Let $q_e(m, n\,|\,S)$ $[q_0(m, n\,|\,S)]$ be the number of such partitions into an even [odd] number of distinct parts. Put $A=\{(a,a)\,|\,a\in\mathrm{N}\}$, $B=\{(b,b-1)\,|\,b\in\mathrm{N}\}$, $C=\{(c-1,c)\,|\,c\in\mathrm{N}\}$, $D=\{(2d+1,\ 2d-1)\,|\,d\in\mathrm{N}\}$, $E=\{(2e-1,\ 2e+1)\,|\,e\in\mathrm{N}\}$. It is shown that $q_e(m, n\,|\,A\cup B\cup C)-q_0(m, n\,|\,A\cup B\cup C)=(-1)^r$ or 0 according as $(m, n)=(\frac{1}{2}r(r+1), \frac{1}{2}r(r-1))$ (where $r\in\mathrm{Z}$) or not. Recurrence relations are obtained for $p(m, n\,|\,D\cup E)$ and $p(m, n\,|\,A\cup B\cup C\cup D\cup E)$, but these are incorrect since equations (1.5) [1.8] must be divided by $(1-xy^{-1})$ $[1-x^{-1}y]$ before the reciprocals of

their left-hand sides can be interpreted combinatorially. The correct recurrence for $C(m,n)=p(m,n\,|\,A\cup B\cup C\cup D\cup E)$, for example, is: $C(0,0)=1$, and if $(m,n)\neq(0,0)$,

$$C(m,n) = \sum_{r=1}^{\infty}\left[\sum_{s=0}^{3r-2} C\left(m-\frac{3r^2+r}{2}+s+1,\, n-\frac{3r^2-5r}{2}-s-1\right)\right.$$
$$\left.-\sum_{s=0}^{3r} C\left(m-\frac{3r^2+5r}{2}+s,\, n-\frac{3r^2-r}{2}-s\right)\right].$$

Next, it is shown that the partitions of $(n_1,\cdots,n_s)$ into vectors with at least one odd component are equinumerous with those into distinct vectors. Putting

$$f(x) = \prod_{n=1}^{\infty}(1-x^n)^{-1},\quad F(x) = f(x^2)f(x^3)f(x)^{-2}f(x^6)^{-1},$$
$$G(x) = f(x^2)f(x^3)f(x^{12})f(x)^{-1}f(x^4)^{-1}f(x^6)^{-2},$$

the author evaluates

$$\int_0^1 x^{-1}(G(x)-1)\,dx \quad\text{and}\quad \int_0^1 x^{-1}(F(x)-1)\,dx.$$

The second of these contains an error; the correct result is $2-2\pi/\sqrt{3}$. The paper concludes with a table of the number of partitions of $(49, 49)$ into at most r parts with non-negative components $(1\leq r\leq 98)$.

B. Gordon (Los Angeles, Calif.)

Conway, J. H. 4698

Mrs Perkins's quilt.

Proc. Cambridge Philos. Soc. **60** (1964), 363–368.

Let a square with integral side N be subdivided into squares of integral sides. Let $f(N)$ be the least number of such squares in any proper subdivision with 1 as the g.c.d. of the lengths of the sides. It is shown that $f(N)\leq 6\sqrt[3]{N}+1$. The method is to consider the subdivision of the square into selected rectangles and to note that if $\langle a_1, a_2, \cdots, a_k\rangle$ is the simple continued-fraction decomposition of p/q, $(p,q)=1$, $p<q$, the rectangle of size p by q is divisible into $a_1+a_2+\cdots+a_k$ squares in a simple manner. It is also shown, by network methods, that $f(N)\geq\log_2(N)$. The logarithm is the "natural order" of f. A table of $f(N)$ for $N\leq 100$ is given, and the author conjectures that $f(N)\sim c\log N$, where $c\leq 7/\log(\frac{1}{2}(7+\sqrt{33}))$.

Partition functions and spiralling in plane random walk.

Canad. Math. Bull. **6** (1963), 231–237.

A spiral of n steps on the square lattice in the plane is a path starting at the origin which always turns clockwise or counter-clockwise, never occupies the same position twice, and can be continued to an m-step spiral for every $m>n$. The number of spirals in plane symmetric random walk is calculated. In particular, the author shows that if $N(n)$ is the number of different n-step spirals, then

$$\sum_{n=1}^{\infty} N(n)x^n = [x/(1-x)]\sum_{k=1}^{\infty} x^{k^2}\Big/\prod_{i=1}^{k}(1-x^i)^2.$$

Shen, Mok-Kong 4703

On the generation of permutations and combinations.

Nordisk Tidskr. Informations-Behandling **2** (1962), 228–231.

The author suggests a procedure for generating the $n!$ permutations on n distinct marks in lexicographical order. Taking the marks to be the integers $1(1)n$, suppose that, starting with the permutation $(1, 2, 3, \cdots, n)$, we have arrived at any stage at the permutation $(k_1, k_2, \cdots, k_n)$. The next permutation is produced from this one by the following procedure. (1) Find the largest i such that $k_{i-1}<k_i$; (2) Find the largest j such that $k_{i-1}<k_j$; (3) Interchange k_{i-1} and k_j; (4) Reverse the order of $k_i, k_{i+1}, \cdots, k_n$. This method compares favorably with a rather inefficient additive method proposed by Howell [Math. Comp. **16** (1962), 243–244; MR **26** #2369]. For generating the combinations of n things taken m at a time in lexicographical order the author proposes the following procedure. If the n things are the integers $1(1)n$, and if the current selection is $(k_1, k_2, \cdots, k_m)$ with $k_i<k_{i+1}$ $(i=1(1)m-1)$, the next combination is found as follows. (1) Find the largest i such that $k_i<n-m+i$; (2) Replace k_i by $1+k_i$; (3) Replace k_{i+j} by k_i+j $(j=1(1)m-i)$.

Harrison, Michael A. 4704

On the classification of Boolean functions by the general linear and affine groups.

J. Soc. Indust. Appl. Math. **12** (1964), 285–299.

Author's summary: "The general linear group and the affine group of transformations are defined over the field of two elements and are applied as transformation groups to Boolean functions. Algorithms for counting the number of classes under both groups are derived. The concept of equivalence is extended by allowing complementation of the range of the functions, and the number of such classes is also obtained. The number of classes of invertible Boolean functions is calculated when these groups are considered. Some other problems are stated and solved."

Un'applicazione delle geometrie di Galois a questioni di statistica.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 479–485.

Denote by $M_q^{(r,u)}$ ($u \geq r$, $r \geq 3$) an $r \times u$ matrix over GF(q) such that all subdeterminants of order r and $r-1$ are distinct from zero. The author shows that such matrices exist if and only if $q \geq 3$.

For $q \geq 3$ let $m(r, q)$ denote the largest possible value of u. The author finds the value of $m(r, q)$ for $q-1 \leq r$, for $r=3$ and arbitrary q and for $r>3$ if q is odd and large with respect to r. For arbitrary r and q the author finds lower and upper bounds for $m(r, q)$.

Hanani, Haim 4706

On covering of balanced incomplete block designs.

Canad. J. Math. **16** (1964), 615–625.

Given a set E of v elements and given positive integers k ($k \leq v$) and λ, we understand by balanced incomplete block designs (BIBD) $B[k, \lambda, v]$ a system of blocks (subsets of E) having k elements each such that every pair of elements of E is contained in exactly λ blocks. A set $F \subset E$ covers a given BIBD $B[k, \lambda, v]$ if the intersection of F with every block of $B[k, \lambda, v]$ is nonempty. A set F covering a given BIBD $B[k, \lambda, v]$ is denoted by $F(B[k, \lambda, v])$, or briefly by $F(B)$.

The author considers the following problem raised by H. J. Ryser. Given integers v, k and λ for which some $B[k, \lambda, v]$ exists, find the greatest integer $f(k, \lambda, v)$ such that for any BIBD $B[k, \lambda, v]$ every $F(B)$ has at least $f(k, \lambda, v)$ elements. A set $F(B[k, \lambda, v])$ having $f(k, \lambda, v)$ elements is called minimal.

We say that $v \in B(k, \lambda)$ if there exists a BIBD $B(k, \lambda, v)$. Some of the important results obtained are the following. Theorem 1: Let $v \in B(k, \lambda)$; then $f(k, \lambda, v) \geq (v-1)/(k-1)$. Theorem 2: Let $qu+1 \in B(q+1, \lambda)$. A necessary condition for $f(q+1, \lambda, qu+1) = u$ is the existence of a BIBD $B[q+1, \lambda, u]$. Theorem 3: If there exists a projective plane of order p, then a necessary and sufficient condition for $f(p+1, \lambda, pu+1) = u$ is the existence of a BIBD $B[p+1, \lambda, u]$. These results contain as a particular case the results of Ryser and Fulkerson for $k=3$, $\lambda=1$ [same J. **15** (1963), 371–396; MR **26** #6068]. The complete solution to Ryser's problem for $k=3$ is given by the following theorem. Theorem 7: For every λ, if $v \in B(3, \lambda)$, then

$$\begin{aligned} f(3, \lambda, v) &= \tfrac{1}{2}(v-1) \text{ if } v \equiv 3 \pmod 4 \text{ or if } v \equiv 1 \pmod 4 \\ &\qquad\qquad \text{and } \lambda \equiv 0 \pmod 2, \\ &= \tfrac{1}{2}(v+1) \text{ if } v \equiv 1 \pmod 4 \text{ and } \lambda \equiv 1 \pmod 2, \\ &= \tfrac{1}{2}v \text{ if } v \equiv 0 \pmod 2). \end{aligned}$$

The author makes extensive use of the construction of designs given by himself in [Ann. Math. Statist. **32** (1961), 361–386; MR **29** #4161].

Gould, H. W. 4709

The operator $(a^x\Delta)^n$ and Stirling numbers of the first kind.

Amer. Math. Monthly **71** (1964), 850–858.

The author proves the following operational formulas:

$$(*) \quad \left(a^x \underset{x,h}{\Delta}\right)^n f(x) = \frac{a^{nx}}{h^n}\sum_{j=0}^{n}(-1)^{n-j}\begin{bmatrix} n \\ j\end{bmatrix} q^{j(j-1)/2} f(x+jh),$$

where

$$\underset{x,h}{\Delta} f(x) = \frac{f(x+h)-f(x)}{h}$$

and

$$\begin{bmatrix} n \\ k\end{bmatrix} = \prod_{j=1}^{k}\frac{q^{n-j+1}-1}{q^j-1} \qquad (q = a^h);$$

$$(**) \quad \left(a^x \underset{x,h}{\Delta}\right)^n f(x) = $$

$$\frac{a^{nx}}{h^n}\sum_{k=0}^{n} h^k \underset{x,h}{\Delta^k} f(x) \sum_{j=k}^{n}(-1)^{n-j}\begin{bmatrix} n \\ j\end{bmatrix}\binom{j}{k} q^{j(j-1)/2}.$$

When $h \to \infty$, (**) yields

$$(a^x D_x)^n f(x) = a^{nx}\sum_{k=0}^{n}(-1)^{n-k} s(n,k)(\log a)^{n-k} D_x^k f(x),$$

where $s(n, k)$ is a Stirling number of the first kind; this in turn implies

$$(z^2D_z)^n g(z) = z^n \sum_{k=0}^{n} (-1)^{n-k} s(n, k)(zD_z)^k g(z).$$

Finally, a formula inverse to (*) is obtained.

Novák, Vítězslav 4710

A note on a problem of T. Hiraguchi. (Czech. Russian and English summaries)

Spisy Přírod. Fak. Univ. Brno **1962**, 147–149.

The author shows that if G is a non-empty partially-ordered set, with a a maximal element in G, and if there exists in G an element b such that $b<a$, and such that $x<a$ implies $x \leq b$, $x \in G$, then the element a is d-removable. Here an element $a \in G$ is said to be d-removable if $\dim(G-a)=\dim(G)$. The author gives two examples to show that the converse does not hold, and asserts that his results solve a problem of T. Hiraguchi [Sci. Rep. Kanazawa Univ. 4 (1955), no. 1, 1–20; MR **17**, 1045; errata, MR **19**, 1431].

Blyth, T. S. 4711

Matrices over ordered algebraic structures.

J. London Math. Soc. **39** (1964), 427–432.

Three generalisations of a result due to R. D. Luce [Proc. Amer. Math. Soc. **3** (1952), 382–388; MR **14**, 347] are first established. The following is typical. Let $\mathfrak{M}(\mathscr{G})$ be the set of matrices of order $n \times n$ with elements from an ordered groupoid $\mathscr{G}$ which is also a lattice with respect to the ordering, and define $A \leq B \Leftrightarrow a_{ij} \leq b_{ij}$. $AB=C \Leftrightarrow \bigcup_j a_{ij}b_{jk}=c_{ik}$; then $\mathfrak{M}(\mathscr{G})$ is residuated if and only if $\mathscr{G}$ is residuated.

Secondly, the following generalisation of results due to J. H. M. Wedderburn [Ann. of Math. (2) **35** (1934), 185–194] and the reviewer [Proc. Glasgow Math. Assoc. **6** (1963), 49–53; MR **26** #6092] is obtained. If $\mathscr{H}$ is a groupoid which is a union semi-lattice and in which multiplication, though not necessarily commutative, is distributive with respect to unions and which has universal and null elements which are, respectively, a multiplicative unit and a zero, then the set $\mathscr{C}$ of multiplicatively complemented elements ($a \cup a'=1, aa'=0$) in $\mathscr{H}$ forms a Boolean algebra. If I is the Kronecker matrix and $A, B \in \mathfrak{M}(\mathscr{H})$ such that $AB=I=B^TA^T$, then $B=A^T$ and $BA=I$. The necessary and sufficient conditions that A have an inverse are that $A \in \mathfrak{M}(\mathscr{C})$ and $AA^T=I$.

Insel, Arnold J. 4712

A relationship between the complete topology and the order topology of a lattice.

Proc. Amer. Math. Soc. **15** (1964), 847–850.

A complete subset of a lattice L is a non-empty subset $C \subset L$ such that each non-empty subset of C possesses a supremum s and an infimum t in L and $s, t \in C$. The smallest topology for L in which the complete subsets of L are closed is called the complete topology and is designated by $K(L)$. $O(L)$ is the order topology for L. A net (i.e., a directed set of elements) in a set X is called universal if it is eventually in or eventually outside of any subset of X [J. L. Kelley, *General topology*, Van Nostrand, Toronto, Ont., 1955; MR **16**, 1136]. L has the complete separation property if for any two distinct elements x, y of L there exists a finite collection $\mathbf{C}$ of complete subsets of L such that $\mathbf{C}$ covers L and for each $C \in \mathbf{C}$, $x \in C \Rightarrow y \notin C$.

The main result: For any lattice L the following are equivalent. (1) $K(L)$ is Hausdorff; (2) Every universal net in L is order-convergent; (3) Every net in L has an order-convergent subnet; (4) L has the complete separation property. If $K(L)$ is Hausdorff, then $O(L)=K(L)$, and $O(L)$ is compact.

★Lectures on Boolean algebras.

Van Nostrand Mathematical Studies, No. 1.

D. Van Nostrand Co., Inc., Princeton, N.J., **1963**. v+147 *pp.* $2.95.

This is a very good introduction to the theory of Boolean algebras. It contains a discussion of all fundamental notions like subalgebras, homomorphisms, ideals, filters, complete algebras, σ-complete algebras, etc. α-complete algebras for $\alpha > \aleph_0$ are not discussed. The book contains almost no references to the literature.

Contents: Boolean rings. Boolean algebras. Fields of sets. Regular open sets. Elementary relations. Order. Infinite operations. Subalgebras. Homomorphisms. Free algebras. Ideals and filters. The homomorphism theorem. Boolean σ-algebras. The countable chain condition. Measure algebras. Atoms. Boolean spaces. The representation theorem. Duality for ideals. Duality for homomorphisms. Completion. Boolean σ-spaces. The representation of σ-algebras. Boolean measure spaces. Incomplete algebras. Products of algebras. Sums of algebras. Isomorphisms of factors. Isomorphisms of countable factors. Retracts. Projective algebras. Injective algebras.

GENERAL MATHEMATICAL SYSTEMS

Grätzer, G. [Grätzer, György] 4716

Free algebras over first order axiom systems. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 193–199.

The author clarifies and generalizes the notion of a free algebra of a given kind with β generators, and derives some theorems about them, in particular, existence theorems. The algebras have a not necessarily finite number of finitary operations. A Σ-algebra has operations which satisfy an axiom system Σ. The axioms of Σ are expressible as sentences of the first-order predicate calculus and may involve existential quantifiers as well as universal quantifiers.

If axioms with existential quantifiers occur, the usual definition of a homomorphism of one Σ-algebra into another is replaced by that of a Σ-homomorphism, which is required to preserve all inverses of a set of elements relative to such an operation, in addition to preserving the results of the operation. The free Σ-algebra $F(\beta)$ is then defined to be a Σ-algebra with a set of β generators $\{x_\gamma\}$ such that if A is any Σ-algebra, then any mapping of the generators $\{x_\gamma\}$ onto elements $\{a_\gamma\}$ of A can be extended to a Σ-homomorphism of $F(\beta)$ into A. Such homomorphisms need not be unique. If they are unique, the algebra is called free in the stronger sense.

Some of the theorems about free Σ-algebras $F(\beta)$ are the following. If $F(\beta)$ exists, it is unique up to isomorphism. If $F(\beta)$ exists, so does $F(\delta)$ for all $\delta<\beta$. If $F(n)$ exists for all $n<\omega$, so does $F(\omega)$. If $F(\omega)$ exists, so does $F(\beta)$ for every cardinal β. The author gives a necessary and sufficient condition for the existence of the free Σ-algebra $F(\beta)$ which is too complicated to give here. It requires that there exist a finite upper bound to the number of inverses of a finite set of elements relative to a given compound operation.

If K is a class of algebras with operations of the same type, one can define the free K-algebra $F(\beta)$ with β generators in the usual way without using the notion of inverse. The author considers the relationship between these two notions of free algebra in the case where K is the class of all Σ-algebras. To do this, he introduces the notion of an axiom system with the inverse-preserving property. Finally, he gives a simplified necessary and sufficient condition for the existence of the free Σ-algebra $F(\beta)$ in the classical case where no existential quantifiers occur in the axiom system Σ.

This paper contains no proofs. Proofs of the results stated are to appear in a later publication.

O. Frink (University Park, Pa.)

Grätzer, György 4717

On the Jordan-Hölder theorem for universal algebras. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 397–406 (1964).

A. W. Goldie [Proc. London Math. Soc. (2) **52** (1950), 107–131; MR **12**, 238] derived forms of the Jordan-Hölder-Schreier theorems for normal series and principal series of subalgebras of an algebra with finitary operations. Here the author simplifies Goldie's proofs. This allows him to prove various generalizations of the theorem.

A normal series $A=A_0\supset A_1\supset\cdots\supset A_n$ of subalgebras of A has associated with it a series $\theta_0,\theta_1,\cdots,\theta_n$ of congruence relations, θ_i being a relation on A_i. The first form of the theorem states that two normal series have isomorphic refinements if their congruence relations are weakly associable over A_n. In a principal series, each A_i is a normal subalgebra, and θ_i is a congruence relation over A, rather than over A_i. The theorem for principal series has the same form as that for normal series.

Noting that the operations of A play little role in the proof, the author considers more generally a class of subsets of A to take the place of the subalgebras, and of mappings between these subsets called homomorphisms. The subsets and homomorphisms satisfy a set of nine axioms. With the proper definitions in terms of these notions, the Jordan-Hölder theorems for normal and principal series are then derived. Only eight axioms are required for normal series.

The generalized theorems are then applied to multialgebras, in which the operations are multivalued, sending ordered sets into subsets rather than elements. They are also applied to ideals in semigroups and groupoids, to multigroups, and to lattices with congruence relations determined by standard ideals.

Some direct decompositions of the set of integers.

Math. Comp. **18** (1964), 537–546.

Let S be the set of non-negative integers whose representation in the scale of 4 does not contain the digits 2 or 3. A pair (M,N) of non-negative integers is called "good" if every non-negative integer can be represented uniquely in the form Ms_1-Ns_2, where each s_i is in S. In an earlier paper [Publ. Math. Debrecen **1** (1950), 232–242; MR **12**, 590] the author listed all good pairs for $1\leq M\leq N\leq 100$. New numerical data obtained with the aid of an IBM 620 computer suggested the existence of three infinite sequences of good pairs, namely $(11,22\cdot 4^k+1)$, $(1,10\cdot 4^k-3)$, and $(2^{2k+2}-3,\ 2^{2k+1}-1)$, where $k=0,1,2,\cdots$. Using

oriented graphs whose vertices are the integers, the author proves that each such pair is indeed good.

Carlitz, L. 4721
Functions and polynomials (mod p^n).
Acta Arith. **9** (1964), 67–78.
Let p be a prime and n an integer $\geqq 1$. Let Z_n denote the ring of integers (mod p^n). A function f over Z_n is a mapping $Z_n \to Z_n$; two such functions, f and g, are equal if $f(a) \equiv g(a)$ (mod p^n) for all $a \in Z_n$. When $n=1$, it is well known that every function is equal to a (not necessarily unique) polynomial, but this is not true for $n>1$.

The author gives the following necessary and sufficient conditions for a function to be equal to a polynomial over Z_n for general n. Theorem 2: $\Delta^r f(0) \equiv 0$ (mod $p^{\nu(r)}$) for $0 \leqq r < p^n$, where $\nu(r) = \min(n, \mu(r))$, $p^{\mu(r)} \| r!$. Theorem 3: $f(x+kp) \equiv \sum_{j=0}^{n-1} (kp)^j f_j(x)$ (mod p^n), where k is an arbitrary integer and the f_j are functions over Z_n. Theorem 4: $\sum_{s=0}^{r} (-1)^{r-s} \binom{r}{s} f(c+sp) \equiv 0$ (mod $p^{\nu(rp)}$) for $0 \leqq r < p^{n-1}$ and $0 \leqq c < p$. Examples are given, and corresponding theorems for functions of two variables are stated without proof.

Some analogues of certain arithmetical functions.
Riv. Mat. Univ. Parma (2) **4** (1963), 115–125.
For positive integers n and r define the unique factoring of n into relatively prime integers $\alpha_r(n)$ and $\beta_r(n)$ by the following rule: If p^k is the highest power of a prime dividing n, let p^k be a factor of $\alpha_r(n)$ or $\beta_r(n)$ according as $k \leqq r$ or $k > r$. Define $\phi_r(n) = \beta_r(n)\phi(\alpha_r(n))$, where ϕ is the Euler totient function. The author studies $\phi_r(n)$ and related functions. This involves the use of the analogue of the Möbius function defined as the multiplicative function such that $\mu_r(p^e) = p^r, -1$, or 0 according as $e=r+1$, $e=1$, or otherwise. The following typical results are cited. First, $\phi_r(n) = n \sum \mu_r(d)/d$, where the sum is taken over all divisors d of n. Also $\sum_{n \leqq x} \phi_r(n)/n = a_r x + O(\log^2 x)$, where $a_r = \prod (1-p^{-2}+p^{-r-2})$, the product being taken over all primes. The sum $\sum_{n \leqq x} \phi_r(n) = \frac{1}{2} a_r x^2 + O(x \log^2 x)$. These estimates are obtained by using classical properties of Dirichlet series.

Diagonal equations over $\mathfrak{p}$-adic fields.
Acta Arith. **9** (1964), 291–300.
Let K be a $\mathfrak{p}$-adic field. It is well known that to each positive integer d there is a constant $\varphi(K,d)$ such that every form of degree d over K in $n \geqq \varphi(K,d)$ variables has a non-trivial zero in K. It has long been conjectured that $\varphi(K,d) = d^2+1$, and this has been verified for $d=2, 3$ and for certain other d, provided the residue class field of K is sufficiently large. Brauer [Bull. Amer. Math. Soc. **51** (1945), 749–755; MR **7**, 108] has shown that a $\varphi(K,d)$ can be determined provided we are given a constant $\psi(K,d)$ such that every diagonal form of degree d over K in $n \geqq \psi(K,d)$ variables has a non-trivial zero in K. When d is a prime the reviewer [Michigan Math. J. **4** (1957), 85–95; MR **18**, 793] and Gray [Doctoral Dissertation, Univ. of Notre Dame, Notre Dame, Ind., 1958] have shown $\psi(K,d) \leqq d(d-1)+1$. When K is the p-adic completion of

the rationals, Davenport and the reviewer [Proc. Roy. Soc. Ser. A **274** (1963), 443–460; MR **27** #3617] have shown that $\psi(K, d) \leq d^2+1$. In this paper the author determines a function $\psi(d)$, which is essentially a dth power, and shows that $\psi(K, d) \leq \psi(d)$ for all $\mathfrak{p}$-adic fields K. The proof involves a careful examination of the expansion of the series $(1+\sum_{i=1}^{\infty} \pi^i y_i)^d$, where π is a prime of K. The expansion varies greatly with the ramification index of K.

Chawla, L. M. 4730
On some abelian groups of equivalence classes over integers and the related favourable Diophantine equations.
J. Natur. Sci. and Math. **4** (1964), 87–92.
The author describes a group he calls $J^{(\mathrm{mod}\ m)}$; this is the multiplicative group of non-zero rational numbers modulo the subgroup of mth powers. *B. J. Birch* (Manchester)

Davenport, H.; Lewis, D. J. 4731
Non-homogeneous cubic equations.
J. London Math. Soc. **39** (1964), 657–671.
Let $\phi(\mathbf{x})$ be a cubic polynomial in n variables with integral coefficients, and let C be the part of ϕ that is homogeneous of degree 3. Define the invariant $h(C)$ as the codimension of the greatest rational linear space contained in the hypersurface $C=0$, so that, for instance, $h(C)=n$ if $C=0$ has no rational point. The authors prove that if $h(C) \geq 17$ and if $\phi(\mathbf{x}) \equiv 0\ (m)$ is soluble for all m, then $\phi(\mathbf{x})=0$ has a solution in integers. Combining this with a theorem of Watson, it follows that $\phi=0$ is soluble in integers whenever $n \geq 20$, $h(C) \geq 4$, and the obvious necessary condition that $\phi \equiv 0\ (m)$ be soluble for all m is satisfied. The main part of the proof is essentially routine, using machinery developed by the authors [Amer. J. Math. **84** (1962), 649–665; MR **26** #2403] and by Davenport alone [Proc. Roy. Soc. Ser. A **272** (1963), 285–303; MR **27** #5734], but it should be added that their version of the machinery is exceedingly well-oiled. A new feature is the curious theorem that if a p-adic integral cubic ψ in at least 15 variables has a p-adic integral zero, then ψ has a non-singular p-adic zero; this can be false for a cubic polynomial in 14 variables. *B. J. Birch* (Manchester)

Oppenheim, A. 4733
The rational integral solution of the equation $a(x^3+y^3)=b(u^3+v^3)$ and allied Diophantine equations.
Acta Arith. **9** (1964), 221–226.
A method of solving the Diophantine equation

$$a(x^3+y^3) = b(u^3+v^3), \qquad (a, b) = 1,\ ab \neq 0,$$

in rational integers x, y, u, v, is presented. Apart from exceptional cases when $a(x+y)^3 = b(u+v)^3$, the remaining solutions are associated with those of a diagonal ternary quadratic equation

$$X^2+3Y^2-3nZ^2 = 0$$

by means of the expression

$$4g^2\{a(x^3+y^3)-b(u^3+v^3)\}-k(a\lambda^3-b\mu^3)\{X^2+3Y^2-3nZ^2\},$$

which vanishes identically under the substitutions

$$(X, Y, Z) = (gk, e, f), \qquad n = ab\lambda\mu,$$
$$x+y = k\lambda, \qquad u+v = k\mu,$$
$$g(x-y) = e\lambda+bf\mu^2, \qquad g(u-v) = e\mu+af\lambda^2.$$

It is indicated that a similar method applies to more general equations of the types:

(1) $$aL^n(x, y)Q(x, y) = bL^n(u, v)Q(u, v)$$

when n is an integer $\neq -2$, L is an integral linear form and Q is an integral quadratic form,

(2) $$p(x, u)Q(x, y) = q(x, u)Q(u, v),$$

where p and q are integers, depending on x and u.

Swinnerton-Dyer, H. P. F. 4734
Rational zeros of two quadratic forms.
Acta Arith. **9** (1964), 261–270.
Let f, g be quadratic forms in 11 variables defined over the rationals; and suppose that for all real λ, μ (not both 0) the form $\lambda f+\mu g$ is indefinite. The author proves that under these conditions f, g have a common non-trivial rational zero. The reality condition is obviously necessary. Previously, Mordell [Abh. Math. Sem. Univ. Hamburg **23** (1959), 126–143; MR **21** #3378] proved a related result assuming 13 variables. The idea behind the proof is to show that, in general, f can be expressed in the form $x_1x_2+\cdots+x_7x_8+h(x_9,\ x_{10},\ x_{11})$ in such a way that $g(x_1, 0, x_3, 0, x_5, 0, x_7, 0, \cdots, 0) = k(x)$ has a non-trivial rational zero. The agreement that f can be so expressed is very intricate and involves some careful byplay between the real condition and the p-adic conditions necessary for the solubility of $k(x)$. Ad hoc arguments are needed when f cannot be so expressed.

Since quadratic forms in 4 variables over the rationals may not have non-trivial rational zeros, clearly 9 variables are needed. On the other hand, Dem'janov [Izv. Akad. Nauk SSSR Ser. Mat. **20** (1956), 307–324; MR **18**, 284] (see also Birch, Lewis and Murphy [Amer. J. Math. **84** (1962), 110–115; MR **25** #52]) has shown that two forms in 9 variables over the rationals have a common non-trivial p-adic zero for each p. Thus one might hope that 9 variables would suffice. The author discusses the possibilities of proving the existence of common non-trivial rational zeros of f, g assuming 9 or 10 variables and possibly a stronger real condition.

Williams, K. S. 4735
A note on the quadratic form $ax^2+2bxy+cy^2$.
Math. Gaz. **48** (1964), 290–291.
The author gives a simple geometric proof of the following well-known result. Let Λ be a 2-dimensional lattice of

determinant $d(\Lambda) \neq 0$. Suppose $a > 0$, $ac > b^2$. Then there is a point $(u, v) \neq (0, 0)$ of the lattice Λ such that

$$au^2 + 2buv + cv^2 \leqq \frac{2}{\sqrt{3}} \sqrt{((ac-b^2)d(\Lambda))}.$$

D. J. Lewis (Ann Arbor, Mich.)

Forder, H. G. 4736

A simple proof of a result on diophantine approximation.

Math. Gaz. **47** (1963), 237–238.

Let p_n/q_n denote the $(n+1)$st convergent in the simple continued fraction for an irrational number ξ, and let a_n denote the $(n+1)$st quotient, so that $q_{n+1} = a_n q_n + q_{n-1}$. A famous theorem of Borel states that at least one of any three successive convergents satisfies

$$\left| \frac{p_n}{q_n} - \xi \right| < \frac{1}{\sqrt{5}q_n^2}.$$

The author gives an elegant and simple proof along the following lines: If the inequality is false for $n = r-1, r, r+1$, the fact that the convergents are successively closer to ξ implies that both ratios q_{r-1}/q_r and q_{r+1}/q_r satisfy the quadratic inequality $t^2 - \sqrt{5}t + 1 \leqq 0$ and therefore lie in the open interval joining $\frac{1}{2}(\sqrt{5} \pm 1)$. This interval has length 1, so $a_r = q_{r+1}/q_r - q_{r-1}/q_r < 1$, a contradiction.

T. M. Apostol (Pasadena, Calif.)

Wright, E. M. 4737

Approximation of irrationals by rationals.

Math. Gaz. **48** (1964), 288–289.

Refer to the foregoing review [#4736]. If k is a positive integer, let $\alpha = \frac{1}{2}(k^2+4)^{1/2}$. Using Forder's simple method, the author proves that if

$$\left| \frac{p_n}{q_n} - \xi \right| \geqq \frac{1}{2\alpha q_n^2}$$

for $n = r-1,\ r,\ r+1$, then $a_r < k$. He then uses this to prove that for any ξ either (i) there is an infinity of rational approximations p/q to ξ such that $q|q\xi - p| < (k^2+4)^{-1/2}$, or (ii) $a_r \leqq k-1$ for all $r \geqq$ some r_0.

Krätzel, E. 4738

Ein Gitterpunktsproblem.

Acta Arith. **10** (1964/65), 215–223.

Denote by $R'_{2k,2}(x)$ the number of integer lattice points (a, b) in the region $a^{2k} + b^{2k} \leqq x$, adjusted if necessary by counting any lattice points on the boundary with multiplicity $\frac{1}{2}$; let V be the volume of the region. Write $F * G$ for the convolution $\int F(\tau)G(t-\tau)\,d\tau$, and $S(x)$ for $\pi^{-1} \sum (\sin 2\pi nx)/n$. The author shows that

$$R'_{2k,2}(x) = \frac{d}{dx}[S(x^{1/2k}) * S(x^{1/2k})],$$

generalising the classical Hardy identity for $R'_{2,2}$; many details are omitted. He attempts to estimate $|R'_{2k,2} - V|$, but makes an error at the head of page 221. The result he is trying to prove was apparently obtained by D. Cauer [Univ. Göttingen, Göttingen, 1914]; far better results may be deduced from the theorem of van der Corput (see Landau, *Vorlesungen über Zahlentheorie*, Hirzel, Leipzig, 1927, esp. Teil 8, Kap. 11–12).

B. J. Birch (Manchester)

Shimura, Goro 4739

On the field of definition for a field of automorphic functions.

Ann. of Math. (2) **80** (1964), 160–189.

As shown in detail by the author in a series of earlier publications [see, for example, same Ann. (2) **79** (1964), 369–409; MR **28** #2104], the study of families of polarised abelian varieties with prescribed algebras of endomorphisms is directly related to certain discontinuous groups and the fields of automorphic functions belonging to these groups. This study is continued here, and leads to the determination of the arithmetical field of definition for the field of moduli of such families in several important cases, viz., the following: (i) The given algebra of endomorphisms L is a totally real algebraic number-field F; (ii) L is a totally indefinite quaternion algebra over F; (iii) L is a totally imaginary quadratic extension of F. In each one of these cases, the family of abelian varieties can be defined by data consisting of a vector-space V over L, an anti-hermitian form T on V, and a lattice M in V; these data determine a semisimple Lie group G and an "arithmetical" discrete subgroup Γ of G; if H is the Riemannian symmetric space belonging to G (with its natural complex structure), the field of moduli of the family in question is in many cases the field of automorphic functions for $\Gamma\backslash G$, or else it is a suitably determined subfield of that field. The purpose of the paper is to show, under suitable restrictions (sometimes of rather delicate arithmetical nature) on the lattice M, that the arithmetical field of definition for the field of moduli is the rational number-field in cases (i) and (ii) and in a certain subcase of (iii), and that otherwise, in case (iii), it is an unramified class-field over a totally imaginary quadratic extension of a totally real field, whose explicit description is given in terms of class-field theory. The proof relies heavily on previous work by the same author, and particularly upon his earlier results on the arithmetical theory of the groups in question. Case (iii), involving, as it does, a generalization of the main result in the theory of complex multiplication for abelian varieties [cf. the author and Y. Taniyama, *Complex multiplication of abelian varieties and its applications to number theory*, Chapter IV, § 15, Math. Soc. Japan, Tokyo, 1961; MR **23** #A2419] and of the concept of "dual CM-types" [ibid., Chapter II, § 8], is by far the most difficult one; a decisive step in the proof consists in showing that a "generic" abelian variety in the family under consideration can be specialized, over an arbitrarily large number-field, to an abelian variety with complex multiplication [as defined, loc. cit., Chapter II, § 6], to which the theory of complex multiplication can then be applied.

A. Weil (Princeton, N.J.)

Ankeny, N. C.; Onishi, H. 4740

The general sieve.

Acta Arith. **10** (1964/65), 31–62.

The authors derive both upper and lower bounds for a large class of sieve problems, on the basis of Selberg's method. Let T be an infinite set of primes, and let T_Y denote the set of all $p \in T$ with $p \leqq Y$. For each N let

S_N be a given set of positive integers. With a fixed $\lambda > 0$, it is required to obtain upper and lower bounds for $M(S_N, T_{N^\lambda})$, i.e., the number of integers $m \in S_N$ which are not divisible by any $p \in T_{N^\lambda}$.

In the following, $\alpha, \beta, \delta, C_1, C_2$ are fixed positive numbers. It is assumed that for each N there exists a positive multiplicative function f_N such that, for every square-free d, the number of m with $m \in S_N$, $m \equiv 0 \pmod{d}$, equals $N(f_N(d))^{-1} + R_d(N)$, where $(f_N(p))^{-1} < 1 - \delta$ for all $p \in T$, and

$$\sum_{d \leq N^\beta} (6\delta^{-2})^{\nu(d)} |R_d| = O(N(\log N)^{-\alpha-2})$$

($\nu(d)$ represents the number of prime divisors of d). Moreover, it is assumed that

$$\sum_{p<X} p(f_N(p))^{-1} < C_1 X (\log X)^{-1} \quad \text{for } X < \log N,$$

$$\sum_{p<X} (p(f_N(p))^{-1} - \alpha) < C_2 X (\log X)^{-2} \text{ for } \log N < X < N^\lambda.$$

With the abbreviation

$$B_\alpha(N) = \Gamma(\alpha) \prod (1 - (f(p))^{-1})(1 - p^{-1})^{-\alpha},$$

where p runs through T_{N^λ}, the main result is as follows.

The expression

$$M(S_N, T_{N^\lambda})(B_\alpha(N))^{-1} N^{-1} (\log N)^\alpha$$

lies between positive bounds depending on α, β, λ only. The bounds which are actually obtained contain $J_\alpha(\beta/2\lambda)$ and $G_\alpha(\beta/2\lambda)$, where J_α and G_α are related to special solutions of the differential-difference equation

$$\tau'(u) = -u^{-1}\{\alpha\tau(u-1) - (\alpha-1)\tau(u)\}.$$

Some applications are given. Let $d_1, \cdots, d_a$ be distinct integers which do not form a complete set of residues for any prime, and $K(\chi) = \prod_{i=1}^a (\chi + d_i)$. Then if a is sufficiently large, there exist infinitely many n for which $\nu(K(n)) < a(\log a + 2)$. Another application is that if we assume the extended Riemann hypothesis, then there exist infinitely many primes q such that $q+2$ has at most three prime factors.

{The reviewer was unable to check as many details as he wished, because of many minor errors and omissions. For example, the very crucial Lemma 3.1 is obscure in several respects, and instead of a proof, there is a reference that seems to be irrelevant.} *N. G. de Bruijn* (Eindhoven)

Zur Abschätzung von $L(1, \chi)$.

Nachr. Akad. Wiss. Göttingen Math.-Phys. Kl. II **1964**, 101–102.

The author shows that there exists an absolute constant c with the following property: For every integer $k \geq 2$ and for every real non-principal character mod k, we have either $L'(1, \chi) > 1$ or $L(1, \chi) \geq c/(\log k)$ (or both).

N. G. de Bruijn (Eindhoven)

Grosswald, E. 4742

A proof of the prime number theorem.

Amer. Math. Monthly **71** (1964), 736–743.

The proof uses the Riemann-Lebesgue theorem for an infinite interval. It is similar in principle to the one outlined (in small print) on pp. 34–35 of the reviewer's Cambridge Tract [*The distribution of prime numbers*, Cambridge Univ. Press, London, 1932], but works with $\Pi(x)$ and $\log \zeta(s)$ (in the notation of the Tract) instead of $\psi(x)$ and $-\zeta'(s)/\zeta(s)$. It is claimed that the proof, though not as short as some or as elementary as others, "seems to have the advantage of great clarity". Such judgments are highly personal; the reviewer merely records his inability to share this view of the proof as presented. Some observations of a more objective kind may, however, be offered. (1) It seems to be assumed (statement and proof of Lemma 1) that, if $f(t)$ is differentiable in a finite interval $[\varepsilon, T]$, then $|f'(t)|$ is integrable in $[\varepsilon, T]$. (2) On p. 740 the wording suggests (in two places) that uniform convergence is sufficient to justify term-by-term integration, even when the range of integration is infinite. (3) The second reference to the Euler-Maclaurin sum formula on p. 737 might well be amplified; it is not clear (to the reviewer) how this formula facilitates the passage from $\zeta(1+it) \neq 0$ to an explicit lower estimate of $|\zeta(1+it)|$ or a uniform upper estimate of $|\log \zeta(\sigma + it)|$ for $1 \leq \sigma \leq c$ (a need not explicitly recognized in the application of Cauchy's theorem at the bottom of p. 740). (4) The argument under (c) on pp. 741–742 is basically sound (though needlessly complicated), but contains statements that are incorrect or inadequate as they stand.

Errata: "A corollary of the Goldbach conjecture".

Duke Math. J. **30** (1963), 683.

The author deletes the Introduction of an earlier paper [same J. **29** (1962), 625–629; MR **26** #88; errata, MR **26**, p. 1544] and replaces it by another.

Moser, W. O. J. 4748

A generalization of some results in additive number theory.

Math. Z. **83** (1964), 304–313.

The author proves the following two results. (I) Let $0\leq f(x)\leq 1$, $0\leq g(x)\leq 1$, $f(x)+g(x)=1$ for $0\leq x\leq 1$, $f(x)=g(x)=0$ otherwise. Let $\alpha=\inf_{0\leq x\leq 1}(1/x)\int_0^x f(y)dy$, $\alpha_0=\int_0^1 f(y)\,dy$. For $0\leq t\leq 1$ put $D(t)=\int_0^{1-t}f(x)g(x+t)dx$, $C=\alpha_0+\sup D(t)$. The author proves

$$C>\alpha+\frac{1+\sqrt{\alpha}+\alpha}{(1+\sqrt{\alpha})^2}\alpha(1-\alpha).$$

(II) Let $f(x)$, $g(x)$ and α_0 be defined as in (I). Let $D(t)=\int_0^1 f(x)g(x+t)dx$. Then if $\alpha_0=\frac{1}{2}$, we have $\max D(t)>0.17675n$. (I) implies a similar result for sequences of integers, and the author states that it implies Kasch's inequality [F. Kasch, same Z. **62** (1955), 368–387; MR **17**, 712]. (II) implies a result by L. Moser [Acta Arith. **5** (1959), 117–119; MR **21** #5594].

In (II) the definitions of $f(x)$ and $g(x)$ in this review are more general than those that appear in the paper. The reviewer assumes that the author intended them to be as stated. *H. B. Mann* (Madison, Wis.)

Rotkiewicz, André 4749

Sur les nombres pseudopremiers pentagonaux.

Bull. Soc. Roy. Sci. Liège **33** (1964), 261–263.

A positive integer n is pseudoprime if n is composite and n divides 2^n-2. The author has shown [see, e.g., #4724 above] that there are infinitely many triangular pseudoprimes and only two square pseudoprimes $<10^{12}$. Here he shows that there are infinitely many pentagonal pseudoprimes. (A pentagonal number is one of the form $\frac{1}{2}k(3k-1)$, where k is a positive integer.) *J. B. Kelly* (Tempe, Ariz.)

Davenport, H.; Erdős, P. 4750

A theorem on uniform distribution. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 3–11.

Let $z_1<z_2<\cdots$ be a sequence of positive real numbers such that $z_n\to\infty$ as $n\to\infty$, and let α be a positive irrational number. For given λ, $0<\lambda<1$, let $F(N)$ be the number of positive integers $k\leq N$ for which $k\alpha$ falls in one of the intervals $(z_j, z_j+\lambda(z_{j+1}-z_j))$. If $F(N)/N\to\lambda$ as $N\to\infty$, for each λ, then the sequence $\{k\alpha\}$ is said to be uniformly distributed relative to the sequence $\{z_j\}$. We suppose that $z_{j+1}\sim z_j$ as $j\to\infty$, since this is easily seen to be necessary for uniform distribution. It follows from work of the reviewer [Pacific J. Math. **3** (1953), 757–771; MR **15**, 511] and Davenport and the reviewer [Michigan Math. J. **10** (1963), 315–319; MR **27** #3619] that $\{k\alpha\}$ is uniformly distributed relative to $\{z_j\}$ for almost all $\alpha>0$ if $z_{j+1}-z_j$ is monotonic. In the present paper this monotonicity condition is considerably weakened. Namely, it is a consequence of the slightly more general theorem actually proved, that if the number of z_j not exceeding N is $O(N^{2-\delta})$, for some fixed $\delta>0$, then $\{N\alpha\}$ is uniformly distributed relative to $\{z_j\}$ for almost all $\alpha>0$.

Davenport, H.; Lewis, D. J. 4755

Character sums and primitive roots in finite fields.

Rend. Circ. Mat. Palermo (2) **12** (1963), 129–136.

Let p be a prime, and denote by $[p^n]$ the finite field with p^n elements. Let χ be a nonprincipal character of the multiplicative group of nonzero elements of $[p^n]$. Each element ξ of $[p^n]$ has a unique representation in the form

$$\xi = x_1\omega_1+\cdots+x_n\omega_n,$$

where $\omega_1, \cdots, \omega_n$ form a basis for $[p^n]$ over $[p]$. Let B be the set of elements ξ for which $N_j<x_j\leq N_j+H_j$ $(j=1, \cdots, n)$, where the N_j and H_j are integers satisfying $0\leq N_j<N_j+H_j<p$ $(j=1, \cdots, n)$. It is shown that then

$$\left|\sum_{\xi\in B}\chi(\xi)\right| < \{p^{1/2}(\log p+1)\}^n,$$

and that when $H_1=\cdots=H_n=H$ and $\delta>0$, there exist $\delta_1(\delta)>0$ and $p_1(\delta)$ such that if $H>p^{n/2(n+1)+\delta}$ and $p>p_1(\delta)$, then

$$\left|\sum_{\xi\in B}\chi(\xi)\right| < (p^{-\delta_1}H)^n.$$

The first of these inequalities generalizes one due to G. Pólya [Nachr. Ges. Wiss. Göttingen Math.-Phys. Kl. **1918**, 21–29] and J. Vinogradoff [Ž. Fiz.-Mat. Obšč. Permsk. Gos. Univ. No. 1 (1918), 94–98] relative to the rational integers, while the second is analogous to a result of D. A. Burgess [Proc. London Math. Soc. (3) **12** (1962), 179–192; MR **24** #A2569]. For $n=1$, the second estimate is valid for $H>p^{1/4+\delta}$, as is the estimate of Burgess.

On transformations by polynomials in two variables.

Colloq. Math. **12** (1964), 53–58.

Let K be a field and X a subset of K. The author has proved [Acta. Arith. 7 (1961/62), 241–249; MR **26** #110; ibid. 8 (1962/63), 11–19; MR **26** #4987] that for a wide class of fields (including all finitely generated extensions of the rationals) if $P(t)$ is a non-linear polynomial with coefficients in K such that $P(X)=X$, then X must be finite. He now considers the analogous problem for transformations in K^n defined by n polynomials in n variables. Now, there are non-linear polynomials with infinite invariant sets. For $n=2$ the following theorem is proved. Let K be a finite algebraic extension of the rationals and let $F_1(x, y)$, $F_2(x, y)$ be homogeneous polynomials with coefficients in K of degrees m_1, m_2, respectively. Suppose that $F_1(x, y)$ and $F_2(x, y)$ have no non-trivial common factor and that m_1, m_2 are greater than 2. Then the transformation T defined in K^2 by $(x, y)\to(F_1(x, y), F_2(x, y))$ has no infinite invariant sets. The theorem holds also in the case $m_1=m_2=2$. The proof depends on the work of the first of the papers referred to. *J. V. Armitage* (Durham)

Application of Dedekind's method to a non-Archimedean ordered field. (Spanish)

Collect. Math. **15** (1963), 77–90.

Let K be a non-archimedean ordered field. The author shows that the Dedekind cut extension Φ of K is a hemiring, that is, an object $\langle R, \cdot, +, 0\rangle$ such that $\langle R, \cdot\rangle$ is a commutative semi-group, $\langle R, +, 0\rangle$ is a commutative monoid, and the set of elements of R with additive inverse forms a subring of R. In a natural way he finds the maximal subfield Σ of Φ and shows (1) $\Sigma\neq\Phi$, and (2) the ordered field Σ is isomorphic to the completion of K by Cauchy sequences. *B. Brainerd* (Toronto, Ont.)

Thaler, Alvin I. 4759

On the Newton polytope.

Proc. Amer. Math. Soc. **15** (1964), 944–950.

In the sequel $K=\{a, a_{ij}, \cdots\}$ denotes a complete field with respect to a non-archimedean rank one valuation $a\to\text{ord }a$ with value group $\mathfrak{G}=\{r, s, \rho, \cdots\}$ which is dense in the additive group of real numbers $R=\{\mu, \nu, b, \cdots\}$. Let $\mathfrak{K}=\{\xi, \eta, \cdots\}$ denote the algebraic closure of K with the corresponding unique prolongation of the valuation. Define Γ_b as $\{\xi\in K:\text{ord }\xi=b\}$. Next set $v(f;\mu,\nu)=\min_{i,j}(\text{ord }a_{ij}+i\mu+j\nu)$ for $f=f(x, y)=\sum a_{ij}x^iy^j\in K[x, y]$. Then the graph of $\Pi_f(X, Y)=\sup_{\mu,\nu\in R}[v(f;\mu,\nu)-\mu X-\nu Y]$ in an (X, Y, Z)-space is called the Newton polytope of f. Furthermore, let $V(f)=\{(\xi,\eta)\in K\times K:f(\xi,\eta)=0\}$, and call $r\in R$ x-distinguished on $V(f)$ if there exist infinitely many $s\in\mathfrak{G}$ such that $V(f)\cap(\Gamma_r\times\Gamma_s)\neq\varnothing$. The author proves the following noteworthy results on the zeros of polynomials f. (1) Let $r, s\in\mathfrak{G}$, and let P_{rs} be the lower plane of support of the Newton polytope of f with $\partial Z/\partial X=-r$, $\partial Z/\partial Y=-s$. Then f has a zero (ξ,η) with ord $\xi=-r$, ord $\eta=-s$ if and only if P_{rs} contains an edge of the polytope. (2) Suppose $f(0,0)\neq0$. Then $\rho\in\mathfrak{G}$ is x-distinguished on $V(f)$ if and only if there is an edge of the Newton polytope of f with direction numbers $(1, 0, -\rho)$. The proofs of these theorems involve skilful geometric considerations in reductions to the one variable case.

Bialynicki-Birula, A. 4760
[Bialynicki-Birula, Andrzej]
On the inverse problem of Galois theory of differential fields.
Proc. Amer. Math. Soc. **15** (1964), 960–964.

If $\mathscr{F}$ is a differential field of characteristic 0 with algebraically closed field of constants $\mathscr{C}$, then the Galois group of a strongly normal extension of $\mathscr{F}$ is (isomorphic with) an algebraic group defined over $\mathscr{C}$. Given $\mathscr{F}$, it is natural to ask what algebraic groups occur in this way. The author proves, in the case in which the differential field is ordinary, that if the transcendence degree of $\mathscr{F}$ over $\mathscr{C}$ is finite and nonzero, then every connected nilpotent affine algebraic group G defined over $\mathscr{C}$ occurs. The idea of the proof is to consider the field $\mathscr{F}(G)$ of rational functions on G which are defined over $\mathscr{F}$, and to extend the given derivation on $\mathscr{F}$ to a derivation on $\mathscr{F}(G)$ which is left-invariant under every element of G which is rational over $\mathscr{C}$; then $\mathscr{F}(G)$, together with this derivation, is a strongly normal extension of $\mathscr{F}$ on the Galois group G.

Harder, Günter 4761
★Über die Galois-Kohomologie der Tori.
Dissertation zur Erlangung des Doktorgrades der Mathematisch-Naturwissenschaftlichen Fakultät der Universität Hamburg, Hamburg, 1963. iii + 71 *pp.*

Let k be a global field, i.e., either a finite algebraic number field or an algebraic function field of one variable over a finite constant field. Let T be an algebraic torus defined over k, i.e., an algebraic group defined over k which is isomorphic over the algebraic closure of k with the product $G_m \times \cdots \times G_m$, G_m being the multiplicative group of the universal domain. Viewing G_m as a trivial torus defined over k, it is natural to ask to what extent the arithmetical properties of G_m can be generalized for an arbitrary torus T defined over k. In this paper the author considers the Hasse principles. A torus T defined over k is said to be split by a finite Galois extension K of k if there exists an isomorphism $T = G_m \times \cdots \times G_m$ defined over K. The author says that the Hasse principle holds for T if the map φ: $H^1(K/k, T) \to H^1(K/k, T_A)$ is injective; here $T_A = T_{A_k}$ means the adelization. The main results are the following: the kernel of φ is always finite (§ 7, Satz 3), and the Hasse principle holds if every Sylow subgroup of the Galois group of K/k is cyclic (§ 6, Satz 8). This paper begins with careful preparations (§ 1–§ 5) which make it self-contained. [Cf. the reviewer's works, Ann. of Math. (2) 74 (1961), 101–139; MR 23 #A1640; ibid. (2) 78 (1963), 47–73; MR 28 #94.]

Tjurin, A. N. 4762
On the classification of two-dimensional fibre bundles over an algebraic curve of arbitrary genus. (Russian)
Izv. Akad. Nauk SSSR Ser. Mat. **28** (1964), 21–52.

Atiyah and Grothendieck gave the classification of vector bundles over an elliptic and over a rational curve [Atiyah, Proc. London Math. Soc. (3) 7 (1957), 414–452; MR 24 #A1274; Grothendieck, Amer. J. Math. 79 (1957), 121–138; MR 19, 315]. The author considers this problem for curves of arbitrary genus. But in this case there is no universal family of bundles, i.e., the functor which to any algebraic variety E associates the set of all families of two-dimensional bundles over the algebraic curve X, parametrized by E, is not representable. Then he introduces the notion of exceptional one-dimensional sub-bundle of a two-dimensional bundle. He proves that any two-dimensional bundle over the curve X of genus g has at most $2g$ exceptional sub-bundles. The new object consisting of a two-dimensional bundle and a fixed exceptional sub-bundle of minimal height is called a quasi-bundle. The author proves that for quasi-bundles there is a universal family whose base B is the union of a finite number of algebraic varieties.

The behaviour of semi-simple algebraic groups under extension of the ground field. (Russian)
Dokl. Akad. Nauk SSSR **158** (1964), 767–769.

Suppose G is a connected semi-simple algebraic group defined over an algebraic number field k. The author asks which G satisfy: (A) G splits (i.e., has a splitting maximal torus) over almost all $\mathfrak{p}$-adic extensions $k_\mathfrak{p}$ of k. The question is answered completely by cohomology. G corresponds to an element h of $H^1(k, A_{\bar{k}})$, where $A_{\bar{k}}$ is the automorphism group (over the algebraic closure $\bar{k}$ of k) of the Lie algebra of G. Let $\beta(h)$ be the natural image of h in $H^1(k, W)$, where W is the quotient of $A_{\bar{k}}$ by its maximal connected subgroup. Then G satisfies (A) if and only if $\beta(h) = 0$.

Marcus, Marvin; Gordon, William R. 4764
Inequalities for mappings on spaces of skew-symmetric tensors.
Duke Math. J. **31** (1964), 691–696.

Let a positive definite Hermitian matrix A of order mk be partitioned into m^2 submatrices A_{ij} $(i, j = 1, 2, \cdots, m)$ each of order k; i.e., A_{ij} is the submatrix of A lying in rows $k(i-1)+1, \cdots, ki$ and columns $k(j-1)+1, \cdots, kj$. For $t = 1, \cdots, m$ let B_t denote the matrix of order t whose (i, j)th entry is $\det A_{ij}$, and let A_t be the principal submatrix of A formed by the first tk rows and columns. By determining the eigenvalues and eigenvectors of a certain Hermitian operator on an appropriate Grassmann space, the authors prove the inequality $(\det B_{t-1})/(\det A_{t-1}) \leq (\det B_t)/(\det A_t)$ for $t = 2, \cdots, m$. Equality holds if and only if $A_{it} = A_{ti} = 0$ $(i = 1, 2, \cdots, t-1)$. As $\det B_1 = \det A_1$, this result implies the inequality $\det A_t \leq \det B_t$ obtained by R. C. Thompson [Canad. Math. Bull. 4 (1961), 57–62; MR 26 #133].

Another proof of the theorems on the eigenvalues of a square quaternion matrix.
Proc. Glasgow Math. Assoc. **6**, 191–195 (1964).

From the author's introduction: "The nature of the eigenvalues of a square quaternion matrix had been considered by Lee [Proc. Roy. Irish Acad. Sect. A 52 (1949), 253–260; MR 12, 153] and Brenner [Pacific J. Math. 1 (1951), 329–335; MR 13, 312]. In this paper the author gives another elementary proof of the theorems on the eigenvalues of a square quaternion matrix by considering the equation $Gy=\mu\bar{y}$, where G is an $n\times n$ complex matrix, y is a nonzero vector in C^n, μ is a complex number, and $\bar{y}$ is the conjugate of y."

Westwick, R. 4766

Linear transformations on Grassmann spaces.

Pacific J. Math. 14 (1964), 1123–1127.

Let U be an n-dimensional vector space over an algebraically closed field, and let G_{nr} be the Grassmann variety (lying in the space $\Lambda^r U$) representing the r-dimensional subspaces of U. Any non-singular linear mapping of U onto itself induces a linear transformation of $\Lambda^r U$ in which G_{nr} is invariant. In this paper it is proved, conversely, that if $n\neq 2r$, any linear transformation of $\Lambda^r U$ which leaves G_{nr} invariant is induced by a linear mapping of U. When $n=2r$, such a linear transformation is either of the type just described or is the composite of such a transformation with that induced by a correlation of the r-dimensional subspaces of U.

Erdős, P.; Rényi, A. 4769

On random matrices. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. 8 (1963), 455–461 (1964).

The permanent of an n-square matrix $A=(a_{ij})$ is defined by $\sum_{\sigma\in S_n}\prod_{i=1}^n a_{i\sigma(i)}$. Let $\mathscr{A}(n,N)$ denote the set of all n-square (0, 1) matrices with N elements equal to 1 and n^2-N elements equal to 0. Let $P(n,N)$ be the probability that a matrix M chosen at random from $\mathscr{A}(n,N)$ has a positive permanent. The authors prove that if $N(n)=n\log n+cn+o(n)$, where c is any real constant, then

$$\lim_{n\to\infty}P(n,N(n))=e^{-2e^{-c}}.$$

This result can be interpreted as follows. If, under the above conditions, the permanent of M is 0, then this is probably due to M having a zero row or a zero column.

ASSOCIATIVE RINGS AND ALGEBRAS

See also 4657, 4778, 5250.

Bergman, G. M. 4770

A ring primitive on the right but not on the left.

Proc. Amer. Math. Soc. 15 (1964), 473–475.

A ring B is right [left] primitive in case it possesses a faithful simple right [left] B-module M. (In this case, B is isomorphic to a dense ring of linear transformations in the right [left] vector space M over K, where K is the field $\mathrm{Hom}_B(M,M)$.) The author presents the first known example of a ring B which is right but not left primitive. The example is, of course, ingenious, and is too complicated to completely describe in this space. The starting point is the field $D=Q(X)$ of rational functions over the rational number field Q, and the ring $A=D[Y,\alpha]$ of noncommuting polynomials $\sum_{i\geq 0}d_iY^i$ defined by the rule $Yd=\alpha(d)Y\ \forall\, d\in D$, where α is the map $d(x)\mapsto d(X^2)$. The first result states that any subring B of A containing both X and Y is right primitive. The author notes that D is a right A-module under the rule $r\cdot Y=r^*\ \forall\, r\in D$, where r^* is the unique element of D satisfying $\frac{1}{2}[r(x)+r(-X)]=r^*(X^2)$, and that the right B-submodule of D generated by X is faithful and simple. By extending the "cyclotomic" valuations (for odd n) of D to A, he obtains a subring B of A, which is the intersection of the valuation subrings corresponding to the extended valuations, which contains both X and Y, and which is not left primitive. It is remarkable that the counterexample B is an integral domain which is embedded in a field (the left quotient field of A).

Carl Faith (Princeton, N.J.)

Wall, C. T. C. 4771

Graded Brauer groups.

J. Reine Angew. Math. 213 (1963/64), 187–199.

Let A be a finite-dimensional associative algebra with 1 over a field k of characteristic $\neq 2$. A is called graded if $A=A_0\oplus A_1$, A_i are nonzero subspaces and $A_iA_j\subseteq A_{i+j}$ (i,j are taken mod 2). A subspace B of A is called graded if $B=B\cap A_0\oplus B\cap A_1$. A graded algebra A is called central if (center of A) $\cap A_0$ consists only of multiples of 1, and is called simple if it has no proper ideals. A typical example of a graded central simple algebra is the Clifford algebra $C(q)$, q being a quadratic form over k, and the motivation of this work was the observation of the fact that when q is the orthogonal sum of q_1,q_2, $C(q)\neq C(q_1)\otimes C(q_2)$ in the usual sense of (ungraded) algebras. The author first determines the structure of a graded central simple algebra $A=A_0\oplus A_1$. Either A or A_0, but not

both, is a central simple (ungraded) algebra over k (Lemma 4). The case where A is central simple is denoted by $(+)$ and where A_0 is so by $(-)$. Then, by the usual structure theory of central simple algebras, it is shown that A is determined by the invariants (ε, n, D, a), where $\varepsilon = \pm$, n a positive integer, D a central division algebra, and $a \in k^*/k^{*2}$ (Theorem 1). Next, he shows that if A, B are graded central simple, then so is $A \otimes B$, where $\otimes$ means the graded tensor product (Theorem 2). He then defines the type of A as the triple (ε, a, D) and proves that the product of types is well-defined and that the types form a group, the graded Brauer group (Theorem 3). (Thus, in the sense of graded algebras, one gets $C(q) = C(q_1) \otimes C(q_2)$ (Theorem 4). It is remarked that, for $C(q)$, ε is the parity of the number of variables of q, a is the discriminant of q, and D is essentially the Hasse-Witt invariant.) The paper concludes with some modifications in characteristic 2. *T. Ono* (Philadelphia, Pa.)

Yuan, Shuen 4772

Differentiably simple rings of prime characteristic.

Duke Math. J. **31** (1964), 623–630.

Let D be a set of derivations on a commutative ring R with identity 1, and assume that 0 and R are the only ideals I of R satisfying $dI \subseteq I$ for all $d \in D$. L. R. Harper, Jr. [Trans. Amer. Math. Soc. **100** (1961), 63–72; MR **24** #A116] showed that if, furthermore, R is a finite-dimensional algebra over an algebraically closed field C, then R is of the form $C[t_1, \cdots, t_n]/(t_1^p, \cdots, t_n^p)$.

In this paper, the author first remarks that R is the direct sum of a field F and the radical N of R, and obtains Harper's conclusion (where C is replaced by F) under the milder assumption that N/N^2 or D^*/ND^* is of finite dimension over F, where D^* is the restricted derivation Lie algebra on R generated by D.

Rimhak Ree (Vancouver, B.C.)

Faith, Carl 4773

Noetherian simple rings.

Bull. Amer. Math. Soc. **70** (1964), 730–731.

The author outlines a proof of the following theorem: If R is a simple ring with identity which contains a minimal complement (= closed = uniform) right ideal, then R is the endomorphism ring of a unital torsion-free module over an integral domain. Consequently, a right noetherian simple ring with identity is isomorphic to the endomorphism ring of a unital torsion-free module of finite rank over an integral domain. Since a right artinian ring with identity is right noetherian, this theorem generalizes the Wedderburn-Artin theorem, which states that a right artinian simple ring with identity is isomorphic to the ring of endomorphisms of a unital module over a division ring.

A. J. Douglas (Sheffield)

Hayes, Allan 4774

A characterisation of f-rings without non-zero nilpotents.

J. London Math. Soc. **39** (1964), 706–707.

An f-ring is a lattice-ordered ring satisfying the condition $a \cap b = 0$, $c \geq 0$, implies $ca \cap b = ac \cap b = 0$. The following non-lattice-theoretic characterization of f-rings without non-zero nilpotents is obtained: A partially ordered ring R without non-zero nilpotent elements is an f-ring if and only if for each $a \in R$ there exist elements a_1 and a_2 in R with $a_1 \geq 0$ and $a_2 \geq 0$ such that $a = a_1 - a_2$ and $a_1 a_2 = a_2 a_1 = 0$. *R. S. Pierce* (Seattle, Wash.)

Weinert, H. J. 4775

Ein Struktursatz für idempotente Halbkörper.

Acta Math. Acad. Sci. Hungar. **15** (1964), 289–295.

Let H be a semifield with non-commutative, idempotent addition, not containing a zero element. The author considers the equivalence on H defined by $x+y+x=x$ and $y+x+y=y$. This is compatible with both addition and multiplication on H: $C_a + C_b = C_{a+b}$, $C_a C_b = C_{ab}$. The class C_e containing the unit element of H forms a subsemifield. The quotient system G is an additively commutative semifield which is universal among all additively commutative homomorphic images of H. $G^\times$ is then the factor group $H^\times/C_e^\times$. Thus, the author discusses also the above decomposition in connection with Schreier's theory of group extensions. *Y. Utumi* (Leeds)

NON-ASSOCIATIVE ALGEBRA

See also 4809, 5116.

Block, Richard E.; Zassenhaus, Hans 4776

The Lie algebras with a nondegenerate trace form.

Illinois J. Math. **8** (1964), 543–549.

A Lie algebra L is said to have trace form (x, y) if there is a representation Δ of L such that $(x, y) = \mathrm{tr}(\Delta x \Delta y)$ for all $x, y \in L$. Over fields of characteristic zero, the structure of Lie algebras with nondegenerate trace forms has been determined by Borel and Mostow [Ann. of Math. (2) **61** (1955), 389–405; MR **16**, 897]; they are direct sums of the center and a semisimple ideal. Over algebraically closed fields F of characteristic $p > 3$, the Lie algebras with nondegenerate trace form and no abelian ideals are determined by results of the first author [Proc. Amer. Math. Soc. **11** (1960), 377–379; MR **22** #5697; Canad. J. Math. **14** (1962), 553–564; MR **25** #3973] and by results of Mills and the reviewer [the reviewer, Mem. Amer. Math. Soc. No. **19** (1956); MR **17**, 1108; Mills and the reviewer, J. Math. Mech. **6** (1957), 519–548; MR **19**, 631; Mills, ibid. **6** (1957), 559–566; MR **19**, 632]; they are direct sums of simple Lie algebras which are analogues of simple complex Lie algebras. In the present paper, the authors drop the assumption that L has no abelian ideals. If F is algebraically closed of characteristic $p > 3$, then L is the direct sum of ideals, orthogonal with respect to the trace form, and each ideal is either (a) one-dimensional; (b) simple with nondegenerate form; or (c) isomorphic to the Lie algebra of all n-by-n matrices with $p \mid n$. When F is not assumed algebraically closed, it is proved that L is the orthogonal direct sum of indecomposable ideals L_i, each L_i being either (a) one-dimensional; (b) simple; or (c) such that its center Z_i is contained in the derived algebra L_i', $L_i'' = L_i'$, $Z_i \cong L_i/L_i'$, and L_i'/Z_i is simple.

Cohn, P. M. 4777

Subalgebras of free associative algebras.

Proc. London Math. Soc. (3) **14** (1964), 618–632.

In an earlier paper [Proc. Cambridge Philos. Soc. 57 (1961), 18–30; MR 22 #9514] the author characterized free associative algebras (f.a.a.) in terms of a degree function which satisfies a generalized Euclidean algorithm. Since $F[x^2, x^3]$ is a non-free subalgebra of the f.a.a. $F[x]$, it is natural to ask how to pick out those subalgebras of an f.a.a. which are free.

Let A be an f.a.a. over a field F with a degree function d, i.e., d is a discrete valuation with rank 1 of A, and let B be a subalgebra of A with 1. A family $\{u_i\}_{i\in I}$ of elements of A is called B-independent if, for every family $\{b_i\}_{i\in I}$ of elements of B, almost all zero,

$$d(\sum u_i b_i) = \max\{d(u_i) + d(b_i)\}.$$

Theorem: Let A be an f.a.a. over a field F with the degree function defined by a free generating set. If B is any subalgebra of A such that A is B-free as a right B-module, and has a B-independent basis, then B is an f.a.a. over F.

This theorem, together with that of Poincaré, Birkhoff and Witt, yields a nice proof of the Širšov-Witt theorem which states that every subalgebra of a free Lie algebra is free. Next follow some results on the problem of deciding whether or not a subset of an f.a.a. A generates a free subalgebra and some results on the structure of the automorphism group of A. These results are used to study the automorphism group of a free Lie algebra L and to prove that every Lie automorphism of L is a succession of elementary (Lie) transformations.

G. Leger (Medford, Mass.)

Roy, Amit 4778

On a characterisation of Clifford algebras.

Math. Z. **85** (1964), 241–244.

Author's introduction: "Sridharan [Trans. Amer. Math. Soc. **100** (1961), 530–550; MR **24** #A754] considered filtered algebras over a commutative ring K whose associated graded algebras are isomorphic to the symmetric algebra of a free K-module M. He showed that such algebras are suitable generalisations of enveloping algebras of Lie algebra structures on M. In this note we ask an analogous question: namely, that of determining filtered algebras whose associated graded algebras are isomorphic to the exterior algebra on a free K-module M. If Q is a quadratic form on M, it is easily verified (Proposition 1) that the Clifford algebra of Q is an algebra of this type. We prove here that if 2 is invertible in K, any filtered algebra whose associated graded algebra is isomorphic to the exterior algebra on M is in fact a Clifford algebra."

G. Leger (Medford, Mass.)

Smith, David A. 4779

On fixed points of automorphisms of classical Lie algebras.

Pacific J. Math. **14** (1964), 1079–1089.

Let A be the automorphism group of a semi-simple Lie algebra over an algebraically closed field of characteristic zero. Let $n(A_i)$ denote the minimal multiplicity of 1 as characteristic root for elements of a connected (algebraic) component A_i of A, and let $m(A_i)$ denote the minimal dimension of fixed-point spaces for elements of A_i. Jacobson [same J. **12** (1962), 303–315; MR **26** #6222] showed that $n(A_i) = m(A_i)$, and determined these numbers. In this paper the above result is extended to the case when the ground field is infinite. For finite ground fields, only the Lie algebras of the types A, B, C, and D are considered, and the same result is obtained for $A_i = G$, the automorphism group of the Lie algebra.

Rimhak Ree (Vancouver, B.C.)

Yamaguti, Kiyosi 4780

On the theory of Malcev algebras.

Kumamoto J. Sci. Ser. A **6**, 9–45 (1963).

This is a general study, along familiar lines, of the structure and representation of a class of algebras defined by identities. Let A be alternative and let A_L be the algebra whose product operation is commutation in A. The alternative identity gives rise to identities in A_L which are then taken to define the class of Malcev algebras. These algebras are closely related to the author's general Lie triple systems and consequently to Lie algebras. For example, Malcev algebras are precisely those algebras M which can be obtained in the following way. Let L be a Lie algebra and D a subalgebra with a complementary D-invariant subspace M in L. Make M an algebra by letting xy be the D component of $[xy]$ for x and y in M.

A standard way to construct a Lie algebra L related as above to a given Malcev algebra M is to form the semi-direct sum of M with its derivation algebra D. It turns out that if M is derived from the Cayley algebra over an algebraically closed field, then L is B_3.

Solvability, the radical, and semi-simplicity are defined for Malcev algebras, and many of the standard general results for Lie algebras go through. Several notions of representation are discussed; in particular, the class of mappings induced in M by representations of its "holomorph" L, and the representations which are derived from an identity satisfied by multiplication operators and which thereby guarantee a "regular" representation. The main results here relate the solvability of M to the solvability of the Lie algebra generated by the representing transformations.

Finally, a cohomology notion based on a specific cochain construction and a class of representations is developed along the lines of the Lie theory with very similar results. If the notion of representation is appropriately chosen, the low-dimensional cohomology groups have the standard interpretation in terms of derivations and extensions.

Ehresmann, Charles 4781

Catégories ordonnées, holonomie et cohomologie.

Ann. Inst. Fourier (*Grenoble*) **14** (1964), *fasc.* 1, 205–268.

From the author's introduction: "Le but de cet article était de développer une théorie de la cohomologie d'une catégorie ordonnée à valeur dans une catégorie et de l'appliquer au cas d'un espace feuilleté. Mais comme l'exposé complet de cette théorie s'est révélé trop long, il a fallu remanier le plan, de sorte que seules les cohomologies d'ordre 0 et 1 sont considérées ici.

"Deux possibilités s'offrent pour définir la cohomologie dans le cas considéré: (1) Généraliser les méthodes utilisées

dans le cas de la cohomologie pour un faisceau, en définissant les classes de cohomologie par un procédé de récurrence à partir des classes d'ordre 0. . . . (2) Généraliser la construction de la cohomologie d'un groupe, à l'aide des foncteurs Ext^n.

"Comme ces deux méthodes, pour les cohomologies d'ordre supérieur, ne s'appliquent que si l'on part d'une catégorie quasi-inductive, le premier problème est de plonger une catégorie ordonnée dans une catégorie quasi-inductive. Nous montrons que la catégorie des atlas réguliers résout cette question pour les groupoïdes ordonnés réguliers. Dans le cas général, il faut utiliser des catégories quotient de la catégorie des fusées et ceci se trouvera dans la suite du présent article."

Kelly, G. M. 4782a

Complete functors in homology. I. Chain maps and endomorphisms.

Proc. Cambridge Philos. Soc. **60** (1964), 721–735.

Kelly, G. M. 4782b

Complete functors in homology. II. The exact homology sequence.

Proc. Cambridge Philos. Soc. **60** (1964), 737–749.

One of the author's objectives in this series of papers is to analyse closely what one might fairly mean by a "complete system of invariants" for the objects of any given category. The second objective is to construct complete functors on several categories of importance in homology theory, and thus to find a complete set of invariants of a chain map, a chain endomorphism, or a pair consisting of a complex and a subcomplex.

In the first paper, some general results on complete functors are given, and then invariants of chain maps and chain endomorphisms are studied. The second paper uses the results of the first, together with a detailed and functorial treatment of the mapping-cylinder construction, to show that the exact homology sequence of a pair of complexes is a complete system of invariants of the pair.

Mitchell, Barry 4783

The full imbedding theorem.

Amer. J. Math. **86** (1964), 619–637.

Theorem: A small abelian category has a full exact imbedding into a category of modules over some ring. This is the result which Freyd adopts as thematic for his book [*Abelian categories*, Harper & Row, New York, 1964; MR **29** #3517].

The idea is to imbed the category $\mathscr{A}$ in the dual of the category $\mathscr{L}(\mathscr{A}, \mathscr{G})$ of kernel-preserving functors from $\mathscr{A}$ to abelian groups by the representation functor $A \to \mathrm{Hom}(A, -) = H^A$. This imbedding is full and exact by the Yoneda theorem. But Freyd [loc. cit.] and Gabriel [Bull. Soc. Math. France **90** (1962), 323–448] showed that $\mathscr{L}(\mathscr{A}, \mathscr{G})$ is abelian. It is easy to see that it has exact direct limits and generator $\sum_{A \in \mathscr{A}} H^A$; it follows from results of Grothendieck [Tôhoku Math. J. (2) **9** (1957), 119–221; MR **21** #1328] that it has an injective cogenerator, and thus its dual is a projective generator U'. Taking $U = \sum_{A \in \mathscr{A}} U'$, the ring is $\mathrm{Hom}(U, U)$ and the imbedding $A \to \mathrm{Hom}(U, H^A)$.

Baumgartner, Ludwig 4784

★Gruppentheorie.

Vierte, erweiterte Auflage. Sammlung Göschen, Band 837/837a.

Walter de Gruyter & Co., Berlin, 1964. 190 *pp.* (3 *inserts*) *DM* 5.80.

The third edition (1958) of this little book was described in MR 21 #1997. This new edition consists essentially of the previous edition plus three additional chapters, which are described in the Table of Contents as follows.

(IX) Abelian groups. 45. Representation of an element of a cyclic group. 46. The cyclic group as direct product of subgroups. 47. Basis of a group. 48. Direct product of given cyclic groups. 49. Isomorphy of Abelian groups with factor groups of U_n (the direct product of n infinite cyclic groups). 50. The subgroups of U_n. 51. Fundamental theorem on finitely-generated Abelian groups. 52. Finite Abelian groups.

(X) Groups with operators. 53. Operator domain of a group; admissible subgroups. 54. Examples of admissible subgroups. 55. Extension of previous concepts and results to groups with operators. 56. A more general view of operator domains. 57. Common operator domain of several groups. 58. Operator isomorphy and homomorphy. 59. Change in the group concept through introduction of operators. 60. The homomorphy and isomorphy theorems for groups with operators. 61. Operator automorphy and endomorphy.

(XI) p-Groups and p-Sylow groups. 62. Results essential to investigation of p-groups. 63. Double coset decomposition of a group and consequences. 64. p-Groups. 65. On the center of a p-group. 66. p-Sylow groups. 67. Theorems on p-Sylow groups. 68. Sylow's theorem.

A third table (on the alternating group A_4 and the dihedral group D_4) has been added, and there are also 57 more exercises (for a total of 151) with solutions indicated.

Although this enlarged version contains a surprising amount of group theory, considering its small size and cost, the book remains something of a curiosity.

W. E. Deskins (E. Lansing, Mich.)

Scott, W. R. 4785

★Group theory.

Prentice-Hall, Inc., Englewood Cliffs, N.J., 1964. xi+479 *pp.* $13.25.

The first sentence of the preface ("This book contains most of the standard basic theorems in group theory, as well as some topics which have not heretofore appeared in book form.") provides a reasonably accurate description. The complete table of contents is as follows.

(1) Introduction. 1.1 Preliminaries. 1.2 Definitions and first properties. 1.3 Permutation groups. 1.4 Examples of groups. 1.5 Operations with subsets. 1.6 Subgroups. 1.7 Cosets and index. 1.8 Partially ordered sets.

(2) Isomorphism theorems. 2.1 Homomorphisms. 2.2 Factor groups. 2.3 Isomorphism theorems. 2.4 Cyclic groups. 2.5 Composition series. 2.6 Solvable groups. 2.7 Operator groups. Homomorphisms. 2.8 Operator groups. Factor groups. 2.9 Operator groups. Isomorphism

theorems. 2.10 Operator groups. Composition series. 2.11 Operator groups. Examples.

(3) Transformations and subgroups. 3.1 Transformations. 3.2 Normalizer, centralizer, center. 3.3 Conjugate classes. 3.4 The transfer.

(4) Direct sums. 4.1 Direct sum of two subgroups. 4.2 Direct sum and product of a set of groups. 4.3 Subdirect products. 4.4 Direct sum of simple groups. 4.5 Endomorphism algebra. 4.6 Remak-Krull-Schmidt theorem. 4.7 Generalizations.

(5) Abelian groups. 5.1 Direct decompositions. 5.2 Divisible groups. 5.3 Free Abelian groups. 5.4 Finitely generated Abelian groups. 5.5 Direct sums of cyclic groups. 5.6 Vector spaces. 5.7 Automorphism groups of cyclic groups. 5.8 Hom(A, B).

(6) p-Groups and p-subgroups. 6.1 Sylow theorems. 6.2 Normalizers of Sylow subgroups. 6.3 p-Groups. 6.4 Nilpotent groups. 6.5 Applications.

(7) Supersolvable groups. 7.1 M-groups. 7.2 Supersolvable groups. 7.3 Frattini subgroup. 7.4 Fitting subgroup. 7.5 Regular p-groups.

(8) Free groups and free products. 8.1 Definitions and existence. 8.2 Presentations. 8.3 Some examples. 8.4 Subgroups of free groups.

(9) Extensions. 9.1 Definitions. 9.2 Semi-direct products. 9.3 Hall subgroups. 9.4 Extensions: General case. 9.5 Split extensions. 9.6 Extensions of Abelian groups. 9.7 Cyclic extensions.

(10) Permutation groups. 10.1 Intransitive groups. 10.2 Transitive groups and representations. 10.3 Regular permutation groups. 10.4 Multiply transitive groups. 10.5 Primitive and imprimitive groups. 10.6 Some multiply transitive groups. 10.7 Numerical applications. 10.8 Some simple groups.

(11) Symmetric and alternating groups. 11.1 Conjugate classes. 11.2 Infinite groups of finite permutations. 11.3 Normal subgroups of symmetric and alternating groups. 11.4 Automorphism groups. 11.5 Imbedding and splitting theorems.

(12) Representations. 12.1 Linear groups. 12.2 Representations and characters. 12.3 The p^iq^j theorem. 12.4 Representations of direct sums. 12.5 Induced representations. 12.6 Frobenius groups. 12.7 Representations of transitive groups. 12.8 Monomial representations. 12.9 Transitive groups of prime degree.

(13) Products of subgroups. 13.1 Factorizable groups. 13.2 Nilpotent times nilpotent. 13.3 Special cases of nilpotent times nilpotent. 13.4 Nilpotent maximal subgroups. 13.5 Transfer theorems. 13.6 Generalized dihedral times odd-order nilpotent. 13.7 S-rings. 13.8 Primitive S-rings over groups of small order. 13.9 S-rings over Abelian groups. 13.10 Nilpotent times dihedral or dicyclic. 13.11 Primitive S-rings over dihedral and dicyclic groups. 13.12 Dihedral or dicyclic times dihedral or dicyclic.

(14) The multiplicative group of a division ring. 14.1 Wedderburn and Cartan-Brauer-Hua theorems. 14.2 Conjugates. 14.3 Subnormal subgroups. 14.4 Subgroups of division rings.

(15) Topics in infinite groups. 15.1 FC groups. 15.2 Composition subgroups and subnormal subgroups. 15.3 Complete groups. 15.4 Existence of infinite Abelian subgroups. 15.5. Miscellaneous exercises. 15.6 A final word.

At the end comes a bibliography of about 160 items, a 4-page index of notation, and a 5-page index.

This large and attractively-printed book has a number of noteworthy features of which the following are only a few. Definitions are presented carefully and precisely so that there is little chance of misinterpretation. A generous number of nontrivial examples is given, and each section closes with a selection of exercises which serve to amplify and illustrate the material covered. Chapter 10 provides a good introduction to permutation groups and includes a development of the Mathieu groups, as well as a discussion of sharply (exactly) doubly and triply transitive groups. The material on products of subgroups (Chapter 13) includes some very interesting and elegant results (such as the Wielandt-Kegel theorems on products of nilpotent subgroups and the Iwasawa characterization of finite supersolvable groups), but the title of the chapter is hardly descriptive. And in Chapters 14 and 15 the author has gathered together additional results from recent papers (some as yet unpublished) which undoubtedly reflect his personal interests.

Of course, the reviewer had some adverse reactions to the book. In spite of the extensive index of notation the author has failed to use the available alphabets and type faces to the reader's advantage. For example, the use of Greek letters for permuted objects and bold-face letters to denote mappings would make Chapter 10 much easier to read. Although the book is advertised as a reference on group theory, the bibliography is not impressive in either size or completeness, and some discussions suffer from curious omissions. In Section 10.6, for example, near-fields are introduced for the purpose of classifying the exactly 2-transitive finite groups, yet no nontrivial example of a near-field is given, and Section 13.4 could easily have included the discussion from J. Thompson's paper (referred to in the book) which is more complete than the author's. On the other hand, some items are included unnecessarily, such as a section (5.6) on vector spaces (no one unfamiliar with vector spaces is apt to be reading page 114 of this book) and elementary material on finite fields (on pages 118, 119, and 282). Presumably, such items are put in to make the book a text which is "as self-contained as possible", but most users will probably wish that the space had been filled in other ways.

The presentation is generally adequate and straightforward, and although a few "Hom's", exact sequences, and commutative diagrams appear (in Chapter 9), the language of homological algebra is not featured. The text seems rather free of misprints.

Certainly the good features of this book far overshadow the others, and any person interested in algebra should find it a useful and informative addition to his library.

★Endlichkeitsbedingungen in der Gruppentheorie.
Mathematische Forschungsberichte, XX.
VEB Deutscher Verlag der Wissenschaften, Berlin, 1963. 88 *pp.* *DM* 14.50.

The present volume consists of translations of three papers: S. N. Černikov [Uspehi Mat. Nauk 14 (1959), no. 5 (89), 45–96; MR 22 #5679] on finiteness conditions in the general theory of groups, O. Ju. Šmidt [*Selected works* (Russian), pp. 298–300, Izdat. Akad. Nauk SSSR, Moscow, 1959; MR 21 #1259] on the local finiteness of a class of infinite

periodic groups, and P. S. Novikov [Dokl. Akad. Nauk SSSR **127** (1959), 749–752; MR **21** #5680] on periodic groups. The text is augmented by comments and additional references by the first author.

Levin, Frank 4787

One variable equations over groups.

Arch. Math. **15** (1964), 179–188.

The problem of adjoining roots of polynomial equations to fields has interesting analogues in the theory of groups. If $g_1, g_2, \cdots$ are elements of a group G, $x_1, x_2, \cdots, x_n$ are unknown elements of G or of an overgroup of G, and $f(x_1, \cdots, x_n, g_1, g_2, \cdots)$ is a monomial expression in these, a set of m equations

$$f_r(x_1, \cdots, x_n, g_1, g_2, \cdots) = 1$$

is said to form a system of m equations in n variables over G. The equations may or may not have a solution in any overgroup. Thus $x^{-1}gx = 1$, $g \neq 1$, has no solution in any overgroup.

The author proves that if the above set of equations have a solution $x_i = a_i$ in the group $G' = \mathrm{gp}(G, a_1, \cdots, a_n)$, then there exists an overgroup G'' of G' and an element a such that $G'' = \mathrm{gp}(G, a)$.

A group G is (m, n) algebraically closed if any system of m equations in n variables which has a solution in an overgroup of G has a solution in G itself.

The author proves that if G is $(m, 1)$ algebraically closed, it is (m, n) algebraically closed. An application is to prove a theorem originally proved by G. Higman, B. H. Neumann and Hanna Neumann [J. London Math. Soc. **24** (1949), 247–254; MR **11**, 322], namely, that a countable group can be embedded in a two-generator group. In particular, one of the two generators may be chosen of arbitrary order. *D. E. Littlewood* (Bangor)

Rapaport, Elvira Strasser 4788

Groups of order 1.

Proc. Amer. Math. Soc. **15** (1964), 828–833.

If the group with presentation $G = (x_1, x_2, \cdots, x_n; R_1, \cdots, R_n)$ is trivial, then $x_1, \cdots, x_n$ are words in suitable conjugates of $R_1, \cdots, R_n$. The author shows, as an application of Grushko's theorem, that these words form a simple set (a simple set of words in the symbols $y_1, \cdots, y_t$ is a set of elements of the free group F on $y_1, \cdots, y_t$ which can be extended to a set of free generators of F). There follow some brief remarks on various questions connected with the problem of deciding whether or not a group with given presentation is trivial. *P. J. Higgins* (London)

Gaughan, Edward D. 4789

The index problem for infinite symmetric groups.

Proc. Amer. Math. Soc. **15** (1964), 527–528.

For an infinite set M with cardinal X, let $S(X, Y) = \{\sigma: \sigma$ is a permutation on M such that $|\mathrm{spt}\,\sigma| < Y\}$, where $\mathrm{spt}\,\sigma = \{m \in M : \sigma(m) \neq m\}$. Generalizing the results of Onofri [Ann. Mat. Pura Appl. (4) 7 (1929), 103–130], Higman [Publ. Math. Debrecen **3** (1954), 221–226; MR **17**, 234] and Scott [Univ. Kansas Dept. of Math. Rep. No. 5 (1956), 1–22], the author proves the following: If $\aleph_0 < Y \leq X^*$, where X^* is the successor of X, then $S(X, Y)$ has no proper subgroups of index less than X. *H. Nagao* (Osaka)

Wagner, Ascher 4790

A theorem on doubly transitive permutation groups.

Math. Z. **85** (1964), 451–453.

The following result is proved. Let G be a doubly transitive group on a set Ω consisting of $n+1$ points, where n is odd. Further, let the subgroup G_a of G fixing the point a contain a subgroup F_a of even order which is a Frobenius group on the set $\Omega - a$. Then G_a is primitive on $\Omega - a$. The proof uses only elementary properties of permutation groups. *W. Feit* (New Haven, Conn.)

Held, Dieter 4791

Engel conditions and direct decompositions into groups of coprime order.

Illinois J. Math. **8** (1964), 582–585.

Theorem: The following properties of a finite group G and the set of primes π are equivalent. (I) G is a direct product of a π-group and a π'-group. (II) $x^{(3)} \circ y = y^{(3)} \circ x = 1$ for every primary π-element x and every primary π'-element y. (III) (a) $x^{(i)} \circ y = y^{(i)} \circ x = 1$ for every primary π-element x and every primary π'-element y and almost all i. (b) If the simple factor F of G is neither a π-group nor a π'-group, then elements of order 2 in a Sylow subgroup of F commute. The author also raises the question as to whether condition (III) (b) can be deleted in the theorem above. *W. Feit* (New Haven, Conn.)

Russakov, S. A. 4792

Non-simplicity of certain classes of finite groups. (Russian)

Dokl. Akad. Nauk BSSR **8** (1964), 429–431.

Let G be a group of order $g = mn$, where m is the largest π-divisor of g, π a non-empty set of primes. Let $m = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_r^{\alpha_r}$, where $p_1 < p_2 < \cdots < p_r$ and each $\alpha_i > 0$. G is defined to be π-discrete if G has a normal series whose consecutive factors have orders $p_1^{\alpha_1}, p_2^{\alpha_2}, \cdots, p_r^{\alpha_r}, n$, respectively. The author has previously introduced the concepts of $\pi\delta$-, $\pi\Delta$-, $\pi\Delta_1$-groups [Dokl. Akad. Nauk SSSR **127** (1959), 270–271; MR **21** #5676]. In this note it is shown that if $\varphi(m)$ and n are relatively prime, where φ is the Euler function, then $\pi\Delta$-, $\pi\Delta_1$-, strongly π-solvable groups are π-discrete. Moreover, under the same assumptions, $\pi\Delta$-, $\pi\Delta_1$-groups are strongly π-solvable. *P. Fong* (Berkeley, Calif.)

Thompson, John G. 4793

Normal p-complements for finite groups.

J. Algebra **1** (1964), 43–46.

For a finite group G, let $m(G)$ be the minimum number of generators of G, let $d(G)$ be the maximum of $m(A)$ for abelian subgroups A of G, and let $J(G)$ be the subgroup of G generated by the abelian subgroups A of G with $m(A) = d(G)$. The following theorem is proved. If P is a Sylow p-subgroup of G (p odd), and both the centralizer of the center of P and the normalizer of $J(P)$ have normal p-complements, then G has a normal p-complement. The main theorem of an earlier paper by the author [Math. Z. **72** (1959/60), 332–354; MR **22** #8070] is a corollary. *Graham Higman* (Oxford)

Wong, W. J. 4794

A characterization of the Mathieu group M_{12}.

Math. Z. **84** (1964), 378–388.

Author's introduction: "A special case of a theorem of R. Brauer [Proc. Internat. Congr. Mathematicians 1954 (Amsterdam) Vol. I, pp. 209–217, Noordhoff, Groningen, 1957; MR 20 #1709] may be regarded as a characterization of the Mathieu group M_{11} of order 7920 in terms of the centralizers of its involutions. In this paper we give a similar characterization of the Mathieu group M_{12} of order 95040. Theorem: Let $C(\pi_0)$ be the centralizer in M_{12} of an involution π_0 in the centre of a 2-Sylow subgroup of M_{12}. Let G be a finite group such that (i) G contains an involution π whose centralizer $C(\pi)$ in G is isomorphic to $C(\pi_0)$; and (ii) G does not contain three mutually non-conjugate involutions. Then, either G is isomorphic with M_{12}, or G has a unique proper non-trivial normal subgroup N. In the latter case, N is elementary Abelian of order 8, and G/N is isomorphic with the simple group GL(3, 2) of order 168. We prove this theorem by means of computations with characters of G. We can also show that in the second case G is isomorphic with a certain group of non-linear transformations on a 4-dimensional vector space over GF(2)."

W. Moser (Montreal, Que.)

Honest subgroups of abelian groups.

Rend. Circ. Mat. Palermo (2) **12** (1963), 353–356.

Let H be any subgroup and let T be the torsion subgroup of an abelian group A. H is called honest if $na \neq 0 \in H$ implies $a \in H$, where $a \in A$ and n is an integer. Equivalently, H is honest if and only if $gp(a) \cap H = \{0\}$ for every $a \in A - H$. If H is honest, then clearly H is pure. Theorem 1: If H is honest then either $H \subset T$ or $T \subseteq H$. Theorem 2: If $H \subset T$, then H is honest if and only if (i) T is p-primary for some prime p, (ii) H is a direct sum of cyclic subgroups of order p, and (iii) H is a direct summand of A. Theorem 3: If $T \subseteq H$, then H is honest if and only if A/H is torsion-free.

S. Lipschutz (Levittown, N.Y.)

Laffer, W. B.; Mann, H. B. 4796

Decomposition of sets of group elements.

Pacific J. Math. **14** (1964), 547–558.

By $A+B$ [$A-B$] is meant the set of (Abelian group-) sums $a+b$ [$a-b$], $a \in A$, $b \in B$. If C is expressible as a sum $A+B$ of sets each of which has more than two elements, C is said to be decomposable. Let G be cyclic of order $n(n+1)+1$, and suppose no set C of $n+1$ elements exists such that $G = C-C$. [This is true, in particular, for values of $n \leq 1600$ that are not prime powers.] Then every set of n^2 elements of G has a decomposition of the form $\{a_1, a_2\}+B$. Theorem 2: If a set C of three elements is decomposable, then $C = \{a, a+b, a+2b\} = \{a-x, a+b-x\}+\{x, x+b\}$. Theorem 3 provides a partial generalization of Theorem 2 for a set of more than three elements. Theorem 4: For every $s>1$, there exists an Abelian group containing an indecomposable set of $s+1$ elements. A second portion of the paper concerns sums of sets of ordinary integers; gap theorems are given. In particular, Theorem 12 asserts that if $A+B \sim P$, the set of primes, then neither A nor B can be finite, where "$\sim$" means "$=$ except for 0%".

Rangaswamy, K. M. 4797

Full subgroups of abelian groups.

Indian J. Math. **6** (1964), 21–27.

Let G be an abelian group. A subgroup F is full if F contains the socle of G. A subgroup H is absorbing if $x \in H$ whenever $nx \in H$ for some integer n. Clearly, an absorbing subgroup is full. Conversely (Theorem 2), a full subgroup F is absorbing if it is neat, that is, $F \cap pG = pF$ for every prime p. The author investigates some properties of neat subgroups and characterises the class of full subgroups which is (Theorem 5) the class of subgroups having a unique neat hull.

Walker, Carol Peercy 4798

Properties of Ext and quasi-splitting of Abelian groups.

Acta Math. Acad. Sci. Hungar. **15** (1964), 157–160.

Let (*) $0 \to A \to G \xrightarrow{t} B \to 0$ be an exact sequence of Abelian groups representing an element of $\mathrm{Ext}(B, A)$. It is of finite order in $\mathrm{Ext}(B, A)$ if and only if for some integer n the sequence $0 \to A/A[n] \to (A+nG)/A[n] \xrightarrow{t'} nB \to 0$ is splitting exact, where $t'(x+A[n]) = t(x)$. If $A[n]=0$ or if $B[n]=0$, then the condition for (*) to belong to $\mathrm{Ext}(B, A)[n]$ is the splitting exactness of $0 \to A \to A+nG \to nB \to 0$. It is also shown that an Abelian group G is quasi-isomorphic to a group that splits (over its torsion subgroup) if and only if $0 \to G_t \to G \to G/G_t \to 0$ represents an element of finite order in $\mathrm{Ext}(G/G_t, G_t)$, where G_t denotes the torsion subgroup of G. The existence of a non-splitting group which is quasi-isomorphic to a splitting group follows. [Ti Yen has shown (unpublished) that for groups G of finite torsion-free rank the quasi-isomorphy to a splitting group implies that the group G itself splits.]

L. Fuchs (Budapest)

Higman, Graham 4799

Amalgams of p-groups.

J. Algebra **1** (1964), 301–305.

The main aim is the proof of the following elegant theorem. Let $A \cup B$ be an amalgam of two finite p-groups with amalgamation $U = A \cap B$. Then $A \cup B$ is embeddable in a finite p-group if there are chief series of A and B which induce by intersection the same chief series of U. This has, among other things, the following consequences. (1) If U is cyclic, $A \cup B$ is embeddable in a finite p-group. This answers a question put to the author by G. Baumslag. (2) If U is normal in A and in B, and $\mathrm{Aut}_A(U)$ and $\mathrm{Aut}_B(U)$ together generate a p-group, $A \cup B$ is embeddable in a finite p-group. The proof of the main theorem is via wreath products, and the principal steps are as follows. Let A, H by any two groups and θ any homomorphism from A to H, with kernel X. Then a counter-map θ^* is a map from H to A such that $(a\theta \cdot h)\theta^*\theta = a\theta \cdot h\theta^*\theta$ for all a in A, all h in H. Countermaps always exist. To each a in A define an element f_a of the cartesian power X^H by

$$f_a(h) = [(a\theta \cdot h)\theta^*]^{-1} a \cdot h\theta^*.$$

It is readily seen that $a \to (a\theta, f_a)$ is an embedding of A in the wreath product $X \wr H$, which the author terms a standard embedding. There are, of course, very many different standard embeddings. Lemma 1: Let U be a subgroup of A and θ a homomorphism from A to H with kernel X. Given any standard embedding $u \to (u\theta, f_u)$ of U in $X \wr H$, we can find a standard embedding $a \to (a\theta, g_a)$ of A in $X \wr H$ such that $f_u(h)$ and $g_u(h)$ are conjugate in A for all u in U, h in H. This has the important corollary: If $U \cap X$ is in the centre of A, then any standard embedding of U

in $X \wr H$ can be extended to an embedding of A in $X \wr H$. Lemma 2: Let $X \cup Y$ be a normal subamalgam of $A \cup B$ (that is, $X \lhd A$, $Y \lhd B$, and $X \cap U = Y \cap U$), and suppose that $Z = X \cap U$ is central in A and in B. If $X \cup Y$ can be embedded in T and $(A/X) \cup (B/Y)$—with the obvious amalgamation—in H, then $A \cup B$ can be embedded in $T \wr H$. The main theorem is then proved by induction on the product $|A|\,|B|$ and looking at the subgroups of order p in the designated chief series of A and B.

J. Wiegold (Cardiff)

Alperin, J. L. 4800

Centralizers of abelian normal subgroups of p-groups.

J. Algebra **1** (1964), 110–113.

Theorem: "If E is a subgroup of a p-group G, maximal subject to being normal abelian and of exponent p^n, then any element of order at most p^n which centralizes E lies in E, unless perhaps $p = 2$ and $n = 1$." The case $n = 1$ implies a lemma by W. Feit and J. Thompson [Pacific J. Math. **13** (1963), 775–1029; MR **29** #3538]. The dihedral group of order 16 shows that $p^n \neq 2$ is essential.

Corollary: "Let G be a 2-group which has no three-generator abelian normal subgroups. If H is a normal subgroup of G and $H \cong Z_4 \times Z_4$, then any element of order at most four which centralizes H lies in H. Furthermore, the centralizer $C(H)$ of H is a metacyclic group." The second assertion in the corollary is based upon results of N. Blackburn [Proc. London Math. Soc. (3) **11** (1961), 1–22; MR **23** #A208]. *S. Lipschutz* (Levittown, N.Y.)

Kovács, L. G.; Neumann, B. H.; de Vries, H. 4803

Some Sylow subgroups.

Proc. Roy. Soc. Ser. A **260** (1961), 304–316.

If Π denotes a set of prime numbers, a Π-group is a periodic group whose elements have orders divisible by primes in Π only. If G is a group, H is a Π-subgroup of G, then H is contained in a maximal or Sylow Π-subgroup of G.

E. V. Schenkman has proved (oral communication) that if a group G is countable, periodic and locally soluble, then to every pair Π, Π' of complementary sets of primes there exists a Sylow Π-subgroup S and a Sylow Π'-subgroup T such that $ST = G$, $S \cap T = \{1\}$. Conditions for periodicity and local solubility cannot be omitted.

The author shows that, under the conditions of Schenkman's theorem: (i) there may be Sylow Π-subgroups that are complemented, but not by Sylow Π'-subgroups; (ii) there may be Sylow Π-subgroups that are not complemented at all; (iii) there may be continuously many non-isomorphic Sylow Π-subgroups for fixed Π.

For Schenkman's groups and, more generally, for countable locally finite groups all Sylow Π-subgroups for fixed Π have the same order. The author shows that for uncountable groups even this weak proposition may fail to hold. *D. E. Littlewood* (Bangor)

Černobyl'skaja, É. I.; Cikunov, I. K. 4804

Sylow p-subgroups of the orthogonal and symplectic groups of a hyperbolic space. (Russian. English summary)

Ukrain. Mat. Ž. **15** (1963), 290–298.

A nondegenerate hyperbolic space V_{2n} is one with the metric $(X, Y) = \sum_1^n (x_{2i-1}y_{2i} - x_{2i}y_{2i-1})$ [symplectic case] or the metric $(X, Y) = 2\sum_1^n x_{2i-1}y_{2i}$ [orthogonal case]. The characteristic of the underlying field is p, $p \neq 2$; its order is $q = p^k$. The paper is concerned with the Sylow p-subgroup of the group of isometries $G(V_{2n})$ of V_{2n}. These Sylow subgroups have orders $q^{n(n-\eta)}$, where $\eta = 0$ [orthogonal case] or $\eta = 1$ [symplectic case].

Theorem: S is a Sylow subgroup of $G(V_{2n})$ if and only if (a) there is a maximal invariant isotropic subspace $U_n \subset V_{2n}$, and (b) S induces on U_n a Sylow p-subgroup of the group of isometries of U_n. Let S and a maximal invariant isotropic subspace U_n be given; $SU_n \subset U_n$. The subgroup H of S that fixes U_n elementwise is a normal divisor of S; $|H| = q^{(n+1-2\eta)n/2}$. If W_n is a complementary isotropic subspace, then every transformation in S can be written hd, where $h \in H$ and $d \in D_W$, the subgroup of S that transforms W into itself. Moreover, $S = T \cdot H$, where $T \cap H = 1$, $T = S \cap G(U_n)$. In the symplectic [orthogonal] case, H is isomorphic to the additive group of $n \times n$ [skew-] symmetric matrices. This isomorphism can be extended to S in such a way that if $d \in D_W$, then dhd^{-1} corresponds to a conjunctive transformation $\Gamma A \Gamma'$ on this additive group. *J. L. Brenner* (Menlo Park, Calif.)

Wohlfahrt, Klaus 4805

An extension of F. Klein's level concept.

Illinois J. Math. **8** (1964), 529–535.

Let Γ be the modular group, the group of all 2×2 matrices with rational integral elements and determinant 1; let $\Gamma(n)$ be the principal congruence subgroup of level n, the group of all matrices in Γ that are congruent to ± 1 modulo n. F. Klein defined a subgroup G of Γ to be of level ("Stufe") n provided n is the smallest positive integer for which $\Gamma(n) \subset G \subset \Gamma$. Then G is called a congruence subgroup.

The author extends the level concept as follows. Every parabolic matrix P in Γ is conjugate over Γ to a translation by an integer m; $|m|$ is called the amplitude of P. Let $G \subset \Gamma$; then the level of G is defined to be the least common multiple of the amplitudes of all parabolic elements in G. When G is a congruence subgroup, the

Klein level agrees with the level thus defined. The new definition has already demonstrated its importance in (as yet unpublished) research.

Using the new definition, the author proves a number of theorems. Let $\Delta(m)$ be the normal closure in $\Gamma(m)$ of $\begin{pmatrix}1 & m\\ 0 & 1\end{pmatrix}$. It is known that $\Delta(m)=\Gamma(m)$ if $1\le m\le 5$; otherwise $\Delta(m)$ is of infinite index in $\Gamma(m)$ [cf. M. I. Knopp, Proc. Amer. Math. Soc. **14** (1963), 95–97; MR **26** #230]. The author reproves this theorem. He then constructs an infinite set of normal subgroups of Γ of level $m\ge 6$ which, however, are not congruence subgroups in the sense of Klein and so contain no principal congruence subgroup. These are different from the groups of I. Reiner [Illinois J. Math. **2** (1958), 142–144; MR **20** #2379].

Next, by means of a theorem of Fricke, the author proves an arithmetic characterization of Γ^6. Finally, he shows that every subgroup of Γ of index ≤ 6 is a congruence subgroup. *J. Lehner* (College Park, Md.)

Platonov, V. P. 4806

Splittable linear groups. (Russian)

Dokl. Akad. Nauk SSSR **151** (1963), 286–289.

Let $L_n(P)$ be the full linear group of $n\times n$ matrices over the perfect field P. A subgroup G of $L_n(P)$ is splittable if it contains the semisimple and unipotent components g_s and g_u of every element g of G. An algebraic subgroup G of $L_n(P)$ is splittable and the author enunciates with brief indications of proofs a number of theorems to show that the known properties of algebraic G extend to all splittable G. For some of them he has to assume that P is of characteristic 0. At the end there is a brief discussion of the Lie group case.

Typical results are the following. Theorem 1: If G is a splittable locally nilpotent group, then its sets G_s, G_u of semisimple [unipotent] elements are invariant subgroups and $G=G_s\cdot G_u$. Theorem 6: Suppose Char $P=0$, and let $G\subset L_n(P)$ be a soluble group and c^∞ (i.e., $c^\infty\bar{G}\subset G$, where $c^\infty\bar{G}=\bigcap c^i\bar{G}$, $c^0\bar{G}=\bar{G}$, $c^i\bar{G}=\overline{[c^{i-1}\bar{G},\bar{G}]}$ and the bar denotes the Zariski closure). Then G is splittable if and only if it is an S-group ($G=DG_u$, where D is any maximal subgroup consisting only of elements of G_s).

On maximal commutative matrix algebras and maximal commutative matrix groups. (Russian)

Dokl. Akad. Nauk BSSR **8** (1964), 425–428.

Let Δ be a commutative field with more than two elements. The author shows that there is a one-to-one correspondence between L, the maximal commutative subalgebras of the algebra Δ_n of $n\times n$ matrices over Δ on the one hand, and K, the maximal abelian subgroups of the general linear group $\mathrm{GL}(n,\Delta)$ on the other. The correspondence is established by assigning to any algebra $A\in L$ the group A^* of its invertible elements, and to any group $\Gamma\in K$ its linear hull $[\Gamma]$. Conjugacy is preserved both ways. In the exceptional case $\Delta=\mathrm{GF}(2)$ with $n>1$, L has more elements than K. *K. A. Hirsch* (London)

Veldkamp, F. D. 4809

Isomorphisms of little and middle projective groups of octave planes.

Nederl. Akad. Wetensch. Proc. Ser. A **67** = *Indag. Math.* **26** (1964), 280–289.

If C is a Cayley division algebra over a commutative field K of characteristic $\ne 2, 3$, then there is a (by now standard) way to construct a projective plane $\mathbf{P}(C)$ in the Jordan algebra A of hermitian 3×3 matrices over C. On A there is defined a cubic form det. Let S be the group of linear transformations of A leaving det invariant, and let G be the group of linear transformations t of A such that $\det tx=\nu(t)x$ with $\nu(t)\in K$. The factor groups PS, PG of S, G by their centers are the little and the middle projective groups of $\mathbf{P}(C)$. Now the following result is proved: If φ is any isomorphism of PS [PG] onto PS' [PG'], where PS' and PG' are the little and the middle projective groups of some other Cayley plane $\mathbf{P}(C')$, then there is a projective transformation or a correlation τ of the projective plane $\mathbf{P}(C)$ onto $\mathbf{P}(C')$ such that $\varphi(\eta)=\tau^{-1}\eta\tau$ for all $\eta\in PS$ [PG], and this also forces the underlying fields to be isomorphic. For the little projective group of a Cayley plane this was proved by Tae-Il Suh [same Proc. **65** (1962), 320–330; MR **25** #2510a; ibid. **65** (1962), 331–339; MR **25** #2510b]. *O. H. Authors' summary: "Jede ganzzählige Darstellung einer Gruppe von Typus (3, 3) zerfällt in eine endliche Anzahl s unzerfällbarer inäquivalenten Bestandteile ($s \leq 9, 12$), wenn es in dieser Darstellung eine Matrix gibt, die der Gleichung $x^2+x+1=0$ genügt. Die Grade unzerfällbarer Bestandteile sind durch die Zahl 6 beschränkt."

Tamaschke, Olaf 4813

S-rings and the irreducible representations of finite groups.

J. Algebra 1 (1964), 215–232.

An S-ring T of a finite group $\mathfrak{G}$ of order g over the complex number field $\mathbf{C}$ is a subring of the group algebra Γ of $\mathfrak{G}$ over $\mathbf{C}$, having as $\mathbf{C}$-basis the t sums τ_i of elements of certain trivially intersecting sets $\mathfrak{T}_i$ of t_i elements of $\mathfrak{G}$ (called T-classes of $\mathfrak{G}$), such that the inverses of the elements of $\mathfrak{T}_i$ form a T-class $\mathfrak{T}_j=\mathfrak{T}_i^*$, and the union of all $\mathfrak{T}_i$ is $\mathfrak{G}$. The T-class $\mathfrak{T}_1$ containing the identity E of $\mathfrak{G}$ is a subgroup $\mathfrak{L}$ of $\mathfrak{G}$, and T is called unitary if $\mathfrak{T}_1=E$. Commutative S-rings are subrings of the center of Γ. Other important S-rings have as T-classes the double cosets $\mathfrak{L}G\mathfrak{L}$ of $\mathfrak{L}$. Complex functions on $\mathfrak{G}$ that are constant on each $\mathfrak{T}_i$ form an algebra $T^\#$ of T-class functions. For each τ_i, assemble in lexicographic order the $t=\sum y_\nu^2$ coefficients $f_{\alpha\beta}^{(\nu)}(\tau_i)=F_{hi}$ in a complete set of r inequivalent representations $\tau\to F_\nu(\tau)$ of T of degrees y_ν, and thus form the $t\times t$ matrix F. Also, taking any complete set of irreducible $\mathbf{C}$-matrix representations $G\to(d_{\kappa\lambda}^{(\rho)}(G))$ of $\mathfrak{G}$ of degrees x_ρ, let $z_h=\sum x_\rho$, and $\Phi_h(G)=\sum x_\rho d_{\kappa\lambda}^{(\rho)}(G)$, summed for all ρ, κ, λ such that $d_{\kappa\lambda}^{(\rho)}(\tau_i)=F_{hi}$ for all i. Then $\Phi_h(G)=\Phi_{hi}$ for all $G\in\mathfrak{T}_i$. These functions Φ_h form a $\mathbf{C}$-basis of $T^\#$, and $\eta_h=\sum_i \Phi_{hi}\tau_i^*/g$ are matrix units for the representations F_ν. Let F^* and Φ^* replace F and Φ when $F_\nu'(\tau^*)$ replaces $F_\nu(\tau)$ and $d_{\lambda\kappa}^{(\rho)}(G^{-1})$ replaces $d_{\kappa\lambda}^{(\rho)}(G)$. Define the $t\times t$ diagonal matrices $T=\operatorname{diag}\{t_i\}$, $Z=\operatorname{diag}\{z_h\}$. Important results in the paper include: $ZF=\Phi T$, $\Phi'F^*=\Phi^*F'=gE_t$, and hence $F'ZF^*=gT$, $\Phi^*T\Phi'=gZ$. Also

$$(\det F/gt_1^{t-1})^2 = \pm(g/t_1)^{t-2}\prod(t_i/t_1)/\prod z_\nu^{y_\nu^2}$$

is a rational integer, which is a square if $\det F$ is rational. Furthermore, when $\det\Phi$ is an algebraic integer, then $g^{t-2}\prod z_\nu^{y_\nu^2}/\prod t_i$ is an integer.

Ballantine, C. S. 4818

A semigroup generated by definite matrices.

J. Analyse Math. 12 (1964), 257–275.

In this paper the author is concerned with the semigroup (under matrix multiplication) $\mathscr{S}$ which is generated by the cone of non-positive definite $N\times N$ matrices as infinitesimal maps, that is, $\mathscr{S}$ is defined as the smallest closed (under the usual topology) semigroup whose cone $\underline{\mathscr{S}}$ of infinitesimal maps contains all non-positive definite $N\times N$ matrices. He shows that $\mathscr{S}$ has no other infinitesimal maps, that is, $\underline{\mathscr{S}}$ is just the cone of non-positive definite $N\times N$ matrices (Theorem 3.1). Except for this theorem, the results on $\mathscr{S}$ are confined to the case $N=2$. The main result is to characterize $\mathscr{S}$ by means of an inequality on the elements of those matrices S which belong to $\mathscr{S}$

(Theorem 2.1) and by finding the extremal matrices of $\mathscr{S}$ (Theorem 2.2). He has some results on the possibility of factoring a 2×2 rotation matrix into a product of positive definite matrices (Theorems 2.3 and 2.4). He also shows that all non-trivial (closed) subsemigroups of $\mathscr{S}$ (in the 2×2 case) which (like $\mathscr{S}$) are orthogonally invariant and generated by their respective cones of infinitesimal maps constitute a one-parameter family $\{\mathscr{S}(m): 0\leq m\leq 1\}$ and $\mathscr{S}(m)$ decreases as m increases, with $\mathscr{S}(0)=\mathscr{S}$, $\mathscr{S}(1)$ the obvious Abelian subsemigroup, and the remaining $\mathscr{S}(m)$ each isomorphic to $\mathscr{S}$ (Theorem 4.1). The isomorphism is explicitly given. *T.-S. Wu* (Stanford, Calif.)

Čupona, G'orgi 4819

On completely simple semigroups. (Serbo-Croatian summary)

Glasnik Mat.-Fiz. Astronom. Društvo Mat. Fiz. Hrvatske Ser. II **18** (1963), 159–164.

Author's note: "Most of the results of this paper are contained in the book by A. H. Clifford and G. B. Preston [*The algebraic theory of semigroups*, Vol. I (in Exercises 14 and 15, p. 84, Section 2.7, and Exercise 2(b), p. 97, Section 3.2), Amer. Math. Soc., Providence, R.I., 1961; MR **24** #A2627], which was not available to the author at the time he submitted the paper for publication." *W. E. Deskins* (E. Lansing, Mich.)

Čupona, G'orgi 4820

On semigroups S in which each proper subset Sx is a group. (Serbo-Croatian summary)

Glasnik Mat.-Fiz. Astronom. Društvo Mat. Fiz. Hrvatske Ser. II **18** (1963), 165–168.

The author sketches here a description of the semigroups listed in the title. If S is such a semigroup and $P=\{x: Sx=S\}$, $Q=\{x: x\subset Sx\neq S\}$, and $B=\{x: x\notin Sx\neq S\}$, then $S=Q\cup B\cup P$ with $Q\cap B=Q\cap P=B\cap P=\varnothing$. Q is nonempty and there exists a group G and a set A such that $Q\cong G\times A$, where multiplication in $G\times A$ is defined by $(x,\alpha)(y,\beta)=(xy,\beta)$ for $x,y\in G$ and $\alpha,\beta\in A$. Furthermore, P is a left simple semigroup (if nonempty) and B can be mapped into Q. Then S is characterized in terms of a lengthy list of relations between Q, B, and P. These semigroups form a subclass of the types studied by Št. Schwarz [Acta Sci. Math. (Szeged) **21** (1960), 125–134; MR **24** #A776] and R. Hrmová [Mat.-Fyz. Časopis Sloven. Akad. Vied **11** (1961), 75–80]. *W. E. Deskins* (E. Lansing, Mich.)

Drbohlav, Karel 4821

On finitely generated commutative semigroups.

Comment. Math. Univ. Carolinae **4** (1963), 87–92.

Let S_1 be the additive semigroup of all non-negative integers. S_n is defined by $S_n=S_1\oplus S_{n-1}$ recursively, namely, the direct sum of S_1 and S_n. This paper gives a theorem that the maximum condition for congruence relations holds in S_n ($n=1,2,\cdots$). The proof is given by means of induction on n. For this purpose, several lemmas and a few concepts are prepared. For example, one lemma says that the maximum condition for ideals holds in S_n. The following ideal plays an important rôle. For a congruence C on S_n and $a_1,a_2\in S_1$, an ideal $J(C,a_1,a_2)$ of S_{n-1} is defined to be the set of all $b_1\in S_{n-1}$ such that $a_1\oplus b_1 C a_2\oplus b_2$ for some $b_2\in S_{n-1}$. As the author remarks, the theorem is still true for any finitely generated commutative semigroup. The reviewer adds that all congruence relations on S_n are determined in terms of ideals of S_n and subgroups of a certain group associated with S_n. Then the theorem of this paper can be obtained more simply as one of the consequences. *T. Tamura* (Davis, Calif.)

Kazim, M. A.; Husain, F. 4822

On the postulates defining a subtractive group.

Math. Student **31** (1963), 95–107 (1964).

The authors consider a set S with two binary operations (written ab and $a\underline{b}$, respectively) satisfying: $a,b\in S$ implies ab, $a\underline{b}\in S$, $(a\underline{b})\underline{c}=\underline{a}(\underline{b}c)$, and $a\underline{b}=c$ if and only if $\underline{c}a=b$. They show that S can be turned into a group in such a way that $a\underline{b}=ab^{-1}$ and $\underline{a}b=a^{-1}b$. Thus, the three postulates constitute an alternate way of defining a group. The group is commutative if and only if the following additional postulate is satisfied: $a\underline{b}=\underline{a}b$. These four postulates are shown to be independent, and some consequences of them are derived (e.g., $(a\underline{b})(\underline{a}c)=c\underline{b}$). *E. J. Tully, Jr.* (Davis, Calif.)

Losey, Gerald 4823

On the structure of π-regular semigroups.

Proc. Amer. Math. Soc. **15** (1964), 955–959.

A semigroup S is called π-regular if for every $a\in S$ the descending chain condition on $\{Sa^n;\ n=0,1,\cdots\}$ and $\{a^nS;\ n=0,1,\cdots\}$ holds; equivalently, $xa^{n+1}=a^n=a^{n+1}y$ for some $x,y\in S$ and for some integer $n>0$ [see Azumaya, J. Fac. Sci. Hokkaido Univ. Ser. I **13** (1954), 34–39; MR **16**, 788; Drazin, Amer. Math. Monthly **65** (1958), 506–514; MR **20** #5217; the author and Schneider, Pacific J. Math. **11** (1961), 1089–1098; MR **25** #137]. The author discusses the structure of π-regular semigroups. The author calls a semigroup P a proto-group if P contains a unique maximal group G and if for each $a\in P$ there is an integer $n>0$ such that $a^n\in G$. A proto-group whose unique idempotent is zero is called a nil semigroup. Clearly, proto-groups are π-regular. The most important theorems in this paper are the following. A semigroup S is π-regular if and only if S is the union of proto-groups. If S is commutative or if all the idempotents of S are primitive [see the definition of "primitive" in Clifford and Preston, *Algebraic theory of semigroups*, Vol. I, Amer. Math. Soc., Providence, R.I., 1961; MR **24** #A2627], then S is π-regular if and only if S is a disjoint union of proto-groups. The remaining part of this paper is devoted to the study of the structure of proto-groups. Every proto-group P is obtained as a split extension of a nil semigroup N by a group G. (If $N\subseteq P$, if P is homomorphic onto G and if a subsemigroup of P is isomorphic onto G under the homomorphism of P to G, then P is called a split extension of N by G.) Also a protogroup P is an ideal extension of a group G by a nil semigroup N [see Clifford and Preston, loc. cit.]. The reviewer adds that P is uniquely determined in terms of G, N and a certain mapping of $N-\{0\}$ into G, and that the proto-groups could be treated as a special case of unipotent inversible semigroups due to the reviewer [Kôdai Math. Sem. Rep. **1954**, 93–95; MR **16**, 443]. *T. Tamura* (Davis, Calif.)

Petrich, Mario 4824

The maximal semilattice decomposition of a semigroup.
Math. Z. **85** (1964), 68–82.

First, the author gives proofs for his theorems published earlier in an abstract [see Bull. Amer. Math. Soc. **69** (1963), 342–344; MR **26** #5084]. Next he discusses the N-classes and the semilattice Y of all N-classes: several necessary and sufficient conditions are given for every N-class to be simple, left simple, completely simple, or a group, and for the semilattice Y to be linearly ordered. Moreover, some necessary and sufficient conditions are also given for Y to be linearly ordered and at the same time for every N-class to be simple, left simple, completely simple, or a group. Finally, explicit expressions for $N(x)$ are given for some special classes of semigroups.

G. Szász (Nyiregyháza)

Sankaran, N. 4825

Group embedding and duality in semigroups.
Publ. Math. Debrecen **10** (1963), 63–68.

Let S be a commutative cancellative semigroup with identity. A semigroup $(S, \mathfrak{A})$ is called a uniform semigroup if it has a uniform structure $\mathfrak{A}=\{U_\alpha\}$ such that $(x, y)\in U_\alpha$, $U_\alpha\in\mathfrak{A}$ if and only if $(x+z, y+z)\in U_\alpha$ for each $z\in S$. Let C^+ be the set of all non-negative real numbers and C the set of all real numbers. A continuous additive homomorphism of a uniform semigroup S into C^+ (or into C) is called a character. The set D of all characters of S relative to C^+ is a semigroup, but the set G of all characters of S relative to C is a group. The author proves that D can be embedded into a group if the smallest group H containing an isomorphic image of D (called a group embedding of D) is algebraically isomorphic to G. In the case where G and H have certain uniform structures, G is unimorphic to H (i.e., G is uniformly continuous to H and vice versa). Combining the above theorem with Krishnan's result [J. Indian Math. Soc. (N.S.) **24** (1960), 283–318], the author obtains theorems on the group embedding of the direct sum of dual semigroups with certain uniform structures.

Warne, R. J. 4826

Homomorphisms of d-simple inverse semigroups with identity.
Pacific J. Math. **14** (1964), 1111–1122.

Let S be a d-simple inverse semigroup with identity, namely, a d-simple semigroup with identity such that any two idempotents of S commute. The structure of S is determined by the structure of its right unit semigroup P which satisfies: (1) it is right cancellative, (2) P has an identity, (3) the intersection of two principal left ideals of P is a principal left ideal of P. {With respect to the terminology, "d-simple (same as D-simple) inverse semigroup", see Clifford and Preston [*The algebraic theory of semigroups*, Vol. I, Amer. Math. Soc., Providence, R.I., 1961; MR **24** #A2627]; with respect to its structure, see Clifford [Amer. J. Math. **75** (1953), 547–556; MR **15**, 98].} S is isomorphic with the semigroup consisting of all ordered pairs (a, b) of elements of P in which equality is defined by $(a, b)=(a', b')$ if and only if $a'=\rho a$, $b'=\rho b$, where ρ is a unit in P. The author determines all homomorphisms of a d-simple inverse semigroup S with identity. Let S and S^* be two such semigroups and let P and P^* be their right unit subsemigroups. The first main result is that the homomorphism M of S into S^* is determined in terms of a certain homomorphism N (called an sl-homomorphism) and an element k of P^* in the following way: $(a, b)M=[(aN)k, (bN)k]$, where the square brackets indicate an element of S^*. In particular, S is isomorphic with S^* if and only if P is isomorphic with P^*. If M is an isomorphism of S with S^*, M is determined by an isomorphism N of P with P^* in a one-to-one fashion: $N\leftrightarrow M$. The second main result is concerned with the determination of homomorphisms of P into P^*. Let U be the group of units of P. Then U is a right normal divisor of P [Rédei, Acta Sci. Math. (Szeged) **14** (1952), 252–273; MR **14**, 614]. If L denotes the congruence on P modulo U, then P/L satisfies (1), (2), (3); thus P is a Schreier extension of U by P/L. For P^*, we define U^* and L^* in the same way. A homomorphism M of P into P^* is determined in terms of a homomorphism f of U into U^*, a homomorphism g of P/L into P^*/L^*, and a function h of P/L into U^* such that $(A, a)M=[(Af)(ah), ag]$, where $(A, a)\in P$, $A\in U$, $a\in P/L$. To illustrate the theory, a few examples are given.

A structure theorem for inverse semigroups.
J. Natur. Sci. and Math. **4** (1964), 103–108.

The author establishes a structure theorem for inverse semigroups which is too involved to reproduce here.

J. Kist (University Park, Pa.)

Yusuf, S. M. 4828

Admissible ideals of a semigroup with operators.
J. Natur. Sci. and Math. **4** (1964), 109–124.

The author discusses admissible ideals of a semigroup with operators. He defines admissibly minimal ideals and admissibly 0-minimal ideals and gives examples to show that an admissibly minimal [admissibly 0-minimal] ideal is not necessarily a minimal [0-minimal] ideal. He defines admissibly simple [left admissibly simple, right admissibly simple], and admissibly 0-simple [left and right admissibly 0-simple] semigroups, and shows by examples that admissibly simple [admissibly 0-simple] semigroups need not be simple [0-simple]. He defines the admissible kernel of a semigroup S with operators as the intersection, when it is nonempty, of all the admissible two-sided ideals of S. He proves that an admissible kernel is an admissibly simple subsemigroup of S, and gives a necessary and sufficient condition for a semigroup with operators to be admissibly 0-simple. He also proves that an admissibly 0-minimal two-sided ideal of a semigroup with operators is either a zero semigroup or an admissibly 0-simple subsemigroup of S. He gives a condition which is sufficient, but not necessary, for an admissibly 0-minimal right [left, two-sided] ideal of a semigroup with operators to be 0-minimal. In the final section, he discusses admissible Rees factor semigroups and compares them with admissible factor inverse semigroups.

Homomorphisms of an inverse semigroup.
J. Natur. Sci. and Math. **4** (1964), 125–132.

The author considers certain aspects of the normaliser

and the centralizer of a subset of an inverse semigroup. In addition, he attempts to generalize Chawla's results [same J. 2 (1962), 110–112; MR 26 #3792] to the case of an inverse semigroup. *J. Kist* (University Park, Pa.)

Jakubík, Jan [Jakubík, Ján] 4830

Lexicographic products of partially ordered groupoids. (Russian. German summary)

Czechoslovak Math. J. **14** (89) (1964), 281–305.

$(G, \cdot, \leq)$ is called a u_1-groupoid if it is a partially ordered groupoid with a neutral element e and such that for any $x, y, z \in G$, $x < y \Rightarrow (xz < yz \;\&\; zx < zy)$ and the same holds with "incomparable" instead of "$<$". Let A, B be u_1-subgroupoids of G such that (i) $AB = G$, (ii) $a_1b_1 = a_2b_2 \Rightarrow a_1 = a_2 \;\&\; b_1 = b_2$, (iii) $g_1 = a_1b_1 \;\&\; g_2 = a_2b_2 \Rightarrow g_1g_2 = (a_1a_2)(b_1b_2) \;\&\; [g_1 < g_2 \Leftrightarrow a_1 < a_2 \vee (a_1 = a_2 \;\&\; b_1 < b_2)]$; then G is called a lexicographic product of A, B: $G = A \circ B$. The operation $\circ$ is associative.

If for any pair A, B of lexicographic factors of a u_1-groupoid G we have $\{a | e \leq a \in A\} \subset \{b | e \leq b \in B\} \Rightarrow A \subset B$, and the same holds with "$\geq$" instead of "$\leq$", G is called a u-groupoid. For any pair $G = A_1 \circ \cdots \circ A_n$, $G = B_1 \circ \cdots \circ B_m$ of lexicographic decompositions of a u-groupoid G there exist isomorphic (but not necessarily identical) refinements. Similar results hold for infinite lexicographic products.

Let $\mathcal{G}$ be the set of all lexicographic decompositions (without trivial factors) of a u-groupoid G. $\mathcal{G}$ is ordered by putting $\alpha \leq \beta$ if α is a refinement of β. In $\mathcal{G}$ an equivalence relation $\sim$ is introduced and in $\mathcal{G}/\sim$ order is defined in a natural way; then this quotient structure is a lattice.

Sade, A. 4831

Isotopies d'un groupoïde avec son conjoint.

Rend. Circ. Mat. Palermo (2) **12** (1963), 357–381.

If E is the set of elements and $\times$ the operation of a groupoid, its conjoint is the groupoid with elements E and operation $*$ for which $x * y = z$ if and only if $y \times x = z$.

If the groupoid is a quasigroup, its reciprocal is the groupoid with elements E and operation $\ominus$ for which $z \ominus y = x$ if and only if $x \times y = z$, and its adjoint is the conjoint of the reciprocal of its conjoint.

An isotopy is a trio ξ, η, ζ of permutations of E for which $x\xi \cdot y\eta = z\zeta$ if and only if $x \times y = z$ for some operation $\cdot$ on E.

The author investigates isotopies between a groupoid and its conjoints, adjoints, and reciprocals.

Sade, A. 4832

Le groupe d'anti-autotopie et l'équation

$$Q(X, X^{-1}, 1) = QP^{12} = Q.$$

J. Reine Angew. Math. **216** (1964), 199–217.

A groupoid $E(\cdot)$ is a set closed under the operation $(\cdot)$. The dual of $E(\cdot)$ is the groupoid $E(\circ)$ defined by the condition $\forall x, y \in E$, $x \cdot y = z \Leftrightarrow y \circ x = z$. The dual of $G = E(\cdot)$ is designated by GP^{12}, where P^{12} stands for the permutation interchanging the first two of the three letters in the equation $x \cdot y = z$. An isotopy mapping a groupoid on its dual is an anti-autotopy. Sometimes the autotopies and anti-autotopies of a groupoid form a group, which then is called its anti-autotopy group. (X, Y, Z) is the notation for the isotopy $E(\cdot) \to E(\circ)$ with $x \cdot y = z \Leftrightarrow xX \circ yY = zZ$.

The author studies the conditions under which a groupoid has an anti-autotopy group. He also discusses the properties of such a group, the isotopies preserving it, and the group generated by the autotopies and the anti-autotopies in the case where no anti-autotopy group exists. Special attention is given to commutative groupoids and their isotopies and, in particular, to those having an autotopy of the type $(X, X^{-1}, 1)$. This leads to the construction of a commutative quasigroup Q which provides the solution to the equation $Q(X, X^{-1}, 1) = Q$.

See also 4657, 4779, 4862, 4868, 5227, 5234, 5592, 5594.

Hofmann, Karl Heinrich 4834

Tensorprodukte lokal kompakter abelscher Gruppen.

J. Reine Angew. Math. **216** (1964), 134–149.

Let $\mathfrak{A}$ be the category of all locally compact Abelian groups and $\mathfrak{B}$ a subcategory. The map $b: G \times H \to A$ $(G, H, A \in \mathfrak{A})$ is a bimorphism if $x \to b(x, h)$ and $y \to b(g, y)$ are morphisms whenever $g \in G$ and $h \in H$ are kept fixed, and if b is continuous at $(0, 0)$. The pair $(T, \otimes)$ with T a topological group and $(x, y) \to x \otimes y$ a bimorphism of $G \times H$ into T is called a $\mathfrak{B}$-tensor product of G and H if (1) the subgroup generated by all $x \otimes y$ is dense in T and (2) to any bimorphism $b: G \times H \to A$, with $A \in \mathfrak{B}$, there is a morphism $b': T \to A$ such that $b(x, y) = b'(x \otimes y)$. If $(T_i, \otimes_i)$ are two $\mathfrak{B}$-tensor products of G and H, and if T_i are locally compact or if one of the T_i is compact, then the $\mathfrak{B}$-tensor products are isomorphic. Several statements can be established showing that $\mathfrak{B}$- and $\mathfrak{C}$-tensor products coincide, where $\mathfrak{B}$ is some smaller, and $\mathfrak{C}$ is some larger, subcategory of $\mathfrak{A}$. Here there is no general construction for the tensor product as in the pure algebraic case. In case we take for $\mathfrak{B}$ the category $\mathfrak{K}$ of all compact groups, then the $\mathfrak{K}$-tensor product of G and H exists and T is the character group of the discrete group of all bimorphisms of G, H into the group of reals mod 1. In several cases the $\mathfrak{A}$-tensor product can be determined more explicitly. Application of tensor products to the theory of Schur multiplicators is also given [cf. the author's paper, Math. Z. **79** (1962), 389–421; MR 27 #3739]. *L. Fuchs* (Budapest)

Platonov, V. P. 4835

Some classes of topological groups. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 784–787.

For this review, G will denote a locally compact topological group and G_0 will denote the component of the identity. Nine theorems and related corollaries are announced without proof. Theorem 2: The group G satisfies the descending chain condition for closed Abelian subgroups if and only if G_0 is a compact Lie group and G/G_0 is a torsion group satisfying the descending chain condition for Abelian subgroups. The author completely characterizes (Theorems 4 and 5) the groups G containing no nontrivial compact subgroups; all such groups are Lie groups. A group G is said to be complete (or divisible) in the sense of Chernikov (CSC) if $\{x^n : x \in G\}$ generates G for all n. Theorem 7: G is CSC if and only if G/G_0 is CSC. Results on locally projective nilpotent and locally projective solvable groups are given. {The author's Theorem 6 also appears as Corollary 2 in Mycielski [Colloq. Math. **5** (1958), 162–166; MR **20** #6479].}

K. A. Ross (New Haven, Conn.)

Bredon, Glen E. 4836

A new treatment of the Haar integral.

Michigan Math. J. **10** (1963), 365–373.

The author presents a new and interesting proof of the existence and uniqueness of a right invariant integral on a locally compact group G. Let L be the set of all continuous real-valued functions defined on G with compact support, and L^+ the subset of L consisting of non-negative functions. For any function f defined on G and any $y \in G$ let $R_y(f)(x) = f(xy)$. For $f, g \in L^+$, we shall say that g dominates f (notation $g \gtrsim f$) if there exist functions $g_1, \cdots, g_n \in L^+$ and elements $x_1, \cdots, x_n \in G$ such that $g = \sum g_i$ and $g'(x) = \sum R_{x_i}(g_i)(x) \geq f(x)$ for all $x \in G$.

Let $g \in L^+$, $g \not\equiv 0$. For any $f \in L^+$ it is shown that the closures of the sets of real numbers $\{s | sg \gtrsim f\}$ and $\{s | sg \lesssim f\}$ intersect in exactly one point, which is defined to be the integral I_g of f. It then follows that one obtains an integral that is uniquely defined up to a multiplicative constant on L^+ which is right invariant. This can then be extended in a unique way to L.

Ernest, John 4838

A new group algebra for locally compact groups.

Amer. J. Math. **86** (1964), 467–492.

Let G be a separable locally compact group. In this paper the author discusses what he calls the "big group algebra" $A(G)$ of G. This turns out to be the second dual of the group C^*-algebra $C^*(G)$ of G and is thus a von Neumann algebra whose normal $*$-representations are in natural one-to-one correspondence with the unitary representations of G. The author's method of defining $A(G)$ is somewhat novel. Fix an infinite-dimensional separable Hilbert space H, and let G^c be the collection of all (concrete) unitary representations of G on H. By an option we mean a function J on G^c whose values are operators on H such that (i) $\sup\{\|J(L)\| : L \in G^c\} < \infty$, and (ii) if $M, N \in G^c$, and U is an isometry of $H \oplus H$ onto H, then $J(U(M \oplus N)U^{-1}) = U(J(M) \oplus J(N))U^{-1}$. The options form a $*$-algebra, in fact, a von Neumann algebra, under the natural pointwise operations; this is the algebra $A(G)$. It contains the other well-known group algebras ($L_1(G), C^*(G)$ and the measure algebra $M(G)$) as weakly dense subalgebras.

{The author has pointed out to the reviewer an error in the last part of the paper. The extension described in Theorem 8.5 (mislabelled 8.3) is not unique. The word "uniquely" in Theorem 8.5 should be deleted. Theorem 9.2 must then be revised to state simply that every invertible element in $A(G)$ which preserves tensor powers is a unitary element. The very interesting question now arises: How much bigger than G itself is the group G_0 of those unitary elements of $A(G)$ which, in addition to satisfying (i) and (ii), preserve tensor products. (For compact groups, of course, $G = G_0$; this is Tannaka's duality theorem.)} *J. M. G. Fell* (Seattle, Wash.)

Kostant, Bertram 4839

Eigenvalues of the Laplacian and commutative Lie subalgebras.

Topology **3** (1964), *suppl.* 2, 147–159.

Soient $\mathfrak{k}$ une algèbre de Lie semi-simple compacte et $\mathfrak{g}$ l'algèbre de Lie complexifiée de $\mathfrak{k}$. Soit θ la représentation linéaire de $\mathfrak{g}$ dans l'algèbre extérieure $\Lambda(\mathfrak{g})$ qui prolonge la représentation adjointe et pour laquelle $\theta(x)$ est une dérivation de $\Lambda(\mathfrak{g})$ quel que soit $x \in \mathfrak{g}$. Pour tout entier $p > 0$, soit S_p la réunion de la famille $\Lambda^p(\mathfrak{a}) \subset \Lambda^p(\mathfrak{g})$ où $\mathfrak{a}$ parcourt l'ensemble des sous-algèbres commutatives de dimension p dans $\mathfrak{g}$ et soit A_p le sous-espace engendré par S_p dans $\Lambda^p(\mathfrak{g})$. L'auteur démontre les théorèmes suivants: (1) tout élément décomposable de A_p appartient à S_p; (2) si $\mathfrak{b}$ est une sous-algèbre résoluble maximale de $\mathfrak{g}$ et si $\mathfrak{a}$ est un idéal commutatif de dimension p de $\mathfrak{b}$, $\Lambda^p(\mathfrak{a})$ engendre dans $\Lambda^p(\mathfrak{g})$, considéré comme module sur $\mathfrak{k}$ par restriction de θ, un sous-module simple $V_{\mathfrak{a}}$ contenu dans A_p; (3) A_p est somme directe de la famille de sous-modules $V_{\mathfrak{a}}$ où $\mathfrak{a}$ parcourt l'ensemble des idéaux commutatifs de dimension p de $\mathfrak{b}$; (4) si $\mathfrak{a}$ et $\mathfrak{a}'$ sont deux idéaux commutatifs distincts dans $\mathfrak{b}$, les modules $V_{\mathfrak{a}}$ et $V_{\mathfrak{a}'}$ ne sont pas isomorphes.

Ces résultats sont démontrés en mettant le sous-espace A_p en rapport avec les valeurs propres du Laplacien $L = d\partial + \partial d$, où ∂ est l'opérateur bord de $\Lambda(\mathfrak{g})$ et où d est l'adjoint de ∂ pour la forme hermitienne que définissent sur $\Lambda(\mathfrak{g})$ la forme de Killing de $\mathfrak{g}$ et la conjugaison par rapport à $\mathfrak{k}$. L'auteur montre que, sur $\Lambda^p(\mathfrak{g})$, les valeurs propres de L sont $\leqq \frac{1}{2}p$ et que A_p est l'ensemble des $u \in \Lambda^p(\mathfrak{g})$ tels que $L(u) = \frac{1}{2}pu$. Cette caractérisation de A_p permet d'obtenir des renseignements détaillés sur sa structure de module sur $\mathfrak{k}$. *J. L. Koszul* (Grenoble)

★**Lineare Darstellungen der Lorentzgruppe.**

Hochschulbücher für Mathematik, Band 57.

VEB Deutscher Verlag der Wissenschaften, Berlin, 1963. ii + 391 *pp.* *DM* 49.50.

A translation into German, with a special foreword by the author, of the classical book *Linear representations of the Lorentz group* (Russian) [Fizmatgiz, Moscow, 1958; MR **21** #4995]. Translations into English and French have already appeared [Engl. transl., Macmillan, New York, 1964; French transl., Dunod, Paris, 1962; MR **25** #2112].

Auslander, L.; Green, L.; Hahn, F. 4841

★Flows on homogeneous spaces.

With the assistance of L. Markus and W. Massey, and an appendix by L. Greenberg. Annals of Mathematics Studies, No. 53.

Princeton University Press, Princeton, N.J., 1963. vii + 107 *pp.* $2.75.

This book is concerned primarily with recent work of the authors in which they study dynamical systems based on manifolds, especially solvmanifolds and nilmanifolds. Some of the results have been announced earlier (L. Auslander, F. Hahn and L. Marcus [Bull. Amer. Math. Soc. **67** (1961), 298–299; MR **22** #A636]; L. W. Green [ibid. **67** (1961), 414–415; MR **22** #A3800]), and the book repeats, in outline, results of A. Mal'cev [Izv. Akad. Nauk SSSR Ser. Mat. **13** (1949), 9–32; MR **10**, 507], G. D. Mostow [Ann. of Math. (2) **60** (1954), 1–27; MR **15**, 853], L. Auslander [Amer. J. Math. **82** (1960), 689–697; MR **22** #A242], I. M. Gel'fand and S. V. Fomin [Uspehi Mat. Nauk (N.S.) 7, no. 1 (47), 118–137 (1952); MR **14**, 660], F. Mautner [Ann. of Math. (2) **65** (1957), 416–431; MR **18**, 929] (and others) needed to make the study self-contained. If G is a solvable connected Lie group and H is a closed subgroup, then G/H is called a solvmanifold. If G is a nilpotent connected Lie group and H is a closed subgroup, G/H is called a nilmanifold. The authors discover that flows on nilmanifolds provide a rich source of examples of minimal sets. For example they provide an infinite number of minimal flows which are distal but not equicontinuous to answer a question of R. Ellis [Pacific J. Math. 8 (1958), 401–405; MR **21** #96]. A solution is given to the problems of determining all connected, simply connected, non-compact, three-dimensional Lie groups G which have a discrete subgroup D such that G/D is compact; then, for each such G, of determining all of the discrete subgroups for which G/D is compact; finally, giving a description of the dynamical behavior of the flows induced on the compact spaces G/D by the one-parameter subgroups of G. The results provide a wide variety of behavior. An application of nilflows is given to obtain a generalization of the Kronecker approximation theorem [J. Koksma, *Diophantische Approximationen*, J. Springer, Berlin, 1936]. Permanent regional transitivity is established for geodesic flows on frames based on three-dimensional compact manifolds of constant negative curvature. *W. R. Utz* (Zbl **106**, 368)

FUNCTIONS OF REAL VARIABLES

See also 4861, 5012, 5057, 5215.

Lipiński, J. S. 4842

On periodic extensions of functions.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 373–375.

The authors prove the existence of infinite sequences $\{I_n\}_{n=1}^{\infty}$ of bounded intervals such that: (1) Every real-valued function on $\bigcup I_n$ which is bounded and uniformly continuous can be extended to a continuous periodic function on the whole real line, and (2) The set of periods of all such extensions has the power of the continuum. Part (1), with "almost-periodic" instead of "periodic", was proved by S. Hartman and C. Ryll-Nardzewski [same Bull. **11** (1963), 427–429; MR **29** #6253].

R. R. Goldberg (Evanston, Ill.)

Sindalovskiĭ, G. H. 4843

The continuity of functions of several variables with respect to congruent sets. (Russian)

Uspehi Mat. Nauk **19** (1964), *no.* 4 (118), 201–207.

Soit $f(P)$, $P=(x_1, x_2, \cdots, x_n)$, une fonction réelle, définie et mesurable dans le domaine $G\subset R^{(n)}$. La fonction $f(P)$ est, par définition, Q-continue sur l'ensemble $E\subset G$, si pour tout point $P_0\in E$, on a

$$\lim_{P\to P_0, P\in Q(P_0)} f(P)=f(P_0);$$

ici on suppose que l'ensemble $Q(P_0)$ est, pour tout $P_0\in E$, congruent à un ensemble fixe, mesurable, Q, ayant l'origine O comme point d'accumulation. On dira que l'ensemble Q appartient à la classe (A) si mes $Q>0$ dans chaque voisinage de O. Théorème 1: Si la fonction $f(P)$, mesurable dans G, est Q-continue sur l'ensemble $E\subset G$ et si l'ensemble Q appartient à la classe (A), alors $f(P)$ est continue, au sens habituel, presque partout dans E.

Pour chaque ensemble Q n'appartenant pas à la classe (A) on peut construire une fonction $f(P)$ mesurable et partout discontinue, mais Q-continue presque partout.

Théorème 2: Si la fonction $f(P)$, mesurable dans G, est Q-continue dans G et si Q est un ensemble de deuxième catégorie dans un certain ensemble ouvert $Q_1\supset Q$, alors $f(P)$ est continue, au sens habituel, presque partout dans G. *S. Marcus* (Bucharest)

Marcus, Solomon 4844

Sur les dérivées dont les zéros forment un ensemble frontière partout dense.

Rend. Circ. Mat. Palermo (2) **12** (1963), 5–40.

The author calls G a Pompeiu function on $[a, b]$ it if has a bounded derivative on $[a, b]$ and if $Z=\{x: G'(x)=0\}$ is a set without interior points, everywhere dense on $[a, b]$. The paper is devoted to a study of such functions and their modifications, e.g., G is of type P_2 if, in the above definition, "bounded derivative" is replaced by "finite derivative"; and G is a Pompeiu function in a generalized sense if, in the above definition, "has a bounded derivative" is replaced by "is continuous and has at each point a derivative, finite or infinite". Using classical results (the bibliography contains 72 titles), the author obtains properties of the various sorts of functions and considers questions such as the measure of Z, the integrability of the derivatives of the functions, etc. In addition, there are sections with the following titles: Improvement of a theorem of Pompeiu; Topological characterizations of the derivative of a Pompeiu function; Operations with Pompeiu functions; Pompeiu functions and derivatives in approximate sense; Pompeiu graph of a derivative and its topological properties; A "discontinuous" analogue of functions of type P_1 in a generalized sense; Open problems; Other applications of Pompeiu functions.

R. A. Rosenbaum (Middletown, Conn.)

Rinehart, R. F.; Wilson, Jack C. 4845

Higher and iterated Hausdorff derivatives.

Rend. Circ. Mat. Palermo (2) 11 (1962), 258–261.

Let $\mathscr{A}$ be a finite-dimensional linear associative algebra with identity over F, the real or complex field. Let f be a function with domain and range in $\mathscr{A}$. Let $\varepsilon_1, \cdots, \varepsilon_n$ be a basis for $\mathscr{A}$ with ε_1 the identity of $\mathscr{A}$. Let

$$\xi = \sum_{i=1}^{n} x_i\varepsilon_i, \qquad x_i \in F, \qquad f(\xi) = \sum_{i=1}^{n} f_i(x_1, \cdots, x_n)\varepsilon_i.$$

Let the component functions $f_i(x_1, \cdots, x_n)$ possess all partial derivatives of mth order in an open set $\mathscr{N}$ of $\mathscr{A}$. Then the mth differential of $f(\xi)$ at a fixed $\xi \in \mathscr{N}$ is defined to be the multilinear function of m variables,

$$d^m(f(\xi); \delta', \cdots, \delta^{(m)}) =$$

$$\sum_{r=1}^{n} \sum_{s_1, s_2, \cdots, s_m = 1}^{m} \frac{\partial^m f_r}{\partial x_{s_m} \partial x_{s_{m-1}} \cdots \partial x_{s_1}} d_{s_1}' d_{s_2}'' \cdots d_{s_m}^{(m)} \varepsilon_r,$$

where $\delta^{(j)} = \sum_{i=1}^{n} d_i^{(j)}\varepsilon_i$, $d_i^{(j)} \in F$, and the partial derivatives are evaluated at ξ. If the mth differential is expressible in the form

$$d^m(f(\xi); \delta', \cdots, \delta^{(m)}) =$$

$$\sum_{i_1, \cdots, i_{m+1} = 1}^{n} g_{i_1 \cdots i_{m+1}} \varepsilon_{i_1} \delta' \varepsilon_{i_2} \delta'' \cdots \delta^{(m)} \varepsilon_{i_{m+1}}$$

(i.e., as a multilinear function of $\delta', \cdots, \delta^{(m)}$, with coefficients in $\mathscr{A}$), where $g_{i_1 \cdots i_{m+1}}$ depend only on ξ, then f is said to be H-differentiable of order m at ξ.

If $f(\xi)$ is H-differentiable of order m in an open set $\mathscr{N}$ of $\mathscr{A}$, then the mth order Hausdorff derivative $d^m f(\xi)/d\xi^m$ of $f(\xi)$ at $\xi \in \mathscr{N}$ is defined to be the "detached coefficient" of the $\delta', \cdots, \delta^{(m)}$ in the mth differential,

$$\frac{d^m f(\xi)}{d\xi^m} = \sum_{i_1, \cdots, i_{m+1} = 1}^{n} g_{i_1 \cdots i_{m+1}} \varepsilon_{i_1} \cdots \varepsilon_{i_{m+1}}.$$

Another type of higher derivative is the iterated first order Hausdorff derivative, $f^{(m)}(\xi)$, defined inductively by $f^{(m)}(\xi) = [f^{(m-1)}]'(\xi)$, $f'(\xi) = df(\xi)/d\xi$, $\xi \in \mathscr{N}$, with an associated concept of iterative H-differentiability of order m.

These two concepts of higher differentiability are not equivalent. However, if $f(\xi)$ is H-differentiable of orders 1 and m in $\mathscr{N}$, then it is shown that $f^{(m)}(\xi)$ exists in $\mathscr{N}$ and that $f^{(m)}(\xi) = d^m f(\xi)/d\xi^m$. *S. Marcus* (Bucharest)

Matuszewska, W. 4846

On a generalization of regularly increasing functions.

Studia Math. 24 (1964), 271–279.

Let φ be continuous and non-decreasing on $[0, \infty)$, vanishing only when $t = 0$, and $\varphi(t) \to \infty$ as $t \to \infty$. If

$$\underline{k}_\varphi(\lambda) = \liminf_{t \to \infty} \frac{\varphi(t)}{\varphi(\lambda t)},$$

$$\bar{k}_\varphi(\lambda) = \limsup_{t \to \infty} \frac{\varphi(t)}{\varphi(\lambda t)},$$

set

$$S_\varphi = \lim_{\lambda \to 0^+} \frac{\log \underline{k}_\varphi(\lambda)}{-\log(\lambda)} = \sup_{0<\lambda<1} \frac{\log \underline{k}_\varphi(\lambda)}{-\log(\lambda)},$$

$$S_\varphi^1 = \lim_{\lambda \to 1^-} \frac{\log \underline{k}_\varphi(\lambda)}{-\log(\lambda)} = \inf_{0<\lambda<1} \frac{\log \underline{k}_\varphi(\lambda)}{-\log(\lambda)}.$$

Similarly, define σ_φ and σ_φ^1 using $\bar{k}_\varphi$. If $S_\varphi^1 = \sigma_\varphi^1 = r_\varphi$ and $r_\varphi < \infty$ (the quantities are all non-negative), then $\bar{k}_\varphi(\lambda) = \lambda^{-r_\varphi} = \underline{k}_\varphi(\lambda)$, so that φ is regularly increasing (and conversely).

Denote by K_C the subclass of those φ such that $\lim_{t\to\infty} \varphi(t\alpha(t))/\varphi(t) = 1$ for all positive functions α on $[0, \infty)$ for which $\alpha(t) \to 1$ as $t \to \infty$.

The class K_C is characterized to be those φ such that $c(\alpha)\varphi(t) \leq \varphi(\alpha t) \leq d(\alpha)\varphi(t)$ for all $t \geq t_0$ and every $\alpha > 1$, where $1 < d(\alpha) < \infty$, $1 \leq c(\alpha)$ and $c(\alpha)$, $d(\alpha) \to 1$ as $\alpha \to 1$. This class contains the slowly varying and all regularly increasing functions. An example indicates a means of constructing others.

Denote by K_C^* those $\varphi \in K_C$ for which the constant $c(\alpha)$ above can be chosen greater than 1 for each $\alpha > 1$. Such functions include convex, as well as integrals of, functions in K_C. Moreover, K_C and K_C^* are shown to be closed under multiplication and composition of functions. Suppose now that φ satisfies the further conditions $\lim_{t\to 0} \varphi(t)/t = 0$, $\lim_{t\to\infty} \varphi(t)/t = \infty$. Set $\varphi^*(s) = \sup_{t \geq 0}(st - \varphi(t))$, the complementary function to φ (there is a misprint in the definition of φ^*). Then $\sigma_\varphi^1 < \infty$ implies $\sigma_\varphi^1 \geq 1$ and $1/S_{\varphi^*}^1 + 1/\sigma_\varphi^1 \leq 1$, while $1 < S_\varphi^1 < \infty$ implies $1/S_\varphi^1 + 1/\sigma_{\varphi^*}^1 \geq 1$. Some further relations between φ and φ^* are also derived, subject to various conditions on φ.

Fiorenza, Renato 4851

Sul prolungamento finitamente o numerabilmente additivo di una funzione modulare in un reticolo.
Ricerche Mat. **12** (1963), 270–301.

Problems on extensions of measures have been investigated by a number of authors, some of which are listed in the bibliography of eight items. Here the problem is to extend measures from one lattice to a larger one by the method of extension by continuity of the measure function. In order to give a sense to continuity it is necessary to introduce suitable topologies. The author gives sufficient conditions for the uniqueness of such an extension which appear general enough to include some well-known conditions. Moreover, it is proved that these conditions are necessary for unicity if only certain types of topologies are to be accepted. It is apparent here that it is just this kind of mixing of topology and measure theory that seems to conflict with the views of A. Denjoy [see, e.g., C. R. Acad. Sci. Paris **257** (1963), 2776–2781; MR **27** #5884].

E. Baiada (Modena)

Neubrunn, T. 4852

Metric spaces associated with a measure space. (Slovak. Russian and English summaries)
Acta Fac. Natur. Univ. Comenian. 7, 663–673 (1963).

Let $(X, \mathfrak{M}, \mu)$ be a measure space such that $\mu(E) > 0$ for every non-empty set E in $\mathfrak{M}$, and let $\{E_t\}_{t\in T}$ be a family of disjoint measurable sets such that $\bigcup E_t = X$ and $\sup\{\mu(E_t) : t \in T\} < \infty$. The author defines a metric on $\mathfrak{M}$ by the formula $\rho(E, F) = A(a)$, where a denotes the bounded function $\mu[(E \dot{-} F) \cap E_t]$, $t \in T$, and A is a functional on the space $l_\infty(T)$ of bounded real-valued functions on T satisfying the following conditions: (1) $A(a) = 0$ if and only if $a = 0$, (2) if $a \leq b$, then $A(a) \leq A(b)$, (3) $A(a+b) \leq A(a) + A(b)$; $E \dot{-} F$ denotes the symmetric difference. {Reviewer's comments: Apparently the author has meant condition (2) to be in the form: (2′) if $0 \leq a \leq b$, then $A(a) \leq A(b)$, namely, he claims that the norm $\|a\| = \sup|a(t)|$ satisfies these conditions, and he uses $A(a)$ only for non-negative a's. In Theorem 3.1, the author assumes that A is additive, which is impossible unless T consists of only one point.}

An example is given to show that the topology of this metric may depend essentially on the choice of the family $\{E_t\}$. Theorem 2.2: If there exists an integer k such that each set E_t is contained in at most k sets of another family $\{F_u\}_{u\in U}$ of disjoint measurable sets such that $\bigcup F_u = X$ and $\sup \mu(F_u) < \infty$, then the convergence determined by $\{F_u\}$ implies that determined by $\{E_t\}$.

The author also defines another pseudo-metric in the case when the measure space is σ-finite and $X = \bigcup E_n$, $E_n \subset E_{n+1}$, $\mu(E_n) < \infty$, using the formula

$$\bar{\rho}(E, F) = \operatorname{Lim} \frac{\mu[(E \dot{-} F) \cap E_n]}{\mu[(E \cup F) \cap E_n]},$$

where Lim denotes a Banach translation-invariant limit (the fractions are meant to be 0 when the denominators vanish). If F and E are of finite measure, then $\bar{\rho}(E, F)$ coincides with a metric introduced by E. Marczewski and H. Steinhaus [Colloq. Math. **6** (1958), 319–327; MR **21** #2721]; if they are of infinite measure, $\bar{\rho}(E, F)$ may be equal to 0 even though $E \dot{-} F$ is not a null set.

Z. Semadeni (Poznań)

Santagati, Giuseppe 4853

Ulteriori osservazioni sulla limitatezza di una funzione numerica definita in un reticolo d'insiemi.
Ricerche Mat. **12** (1963), 262–269.

In a previous paper [same Ricerche **12** (1963), 110–120; MR **27** #3762], conditions were given on the set R of subsets of a given set and a real-valued function φ defined on R to be relatively bounded (for notations and definitions refer to the review cited above).

Here, refinements of the results of the preceding paper are obtained; the hypothesis of conditioned $\cup$-completeness is replaced by its consequence (see the review cited): For any pair $X \supseteq Y$ of R and any real positive σ there exists $I_\sigma \in R$ such that $X \supseteq I_\sigma \supseteq X - Y$ and $\sup|\varphi(J)| < \sigma$ for J in $R_{I_\sigma \cap Y}$; continuity from inside of φ is replaced by the condition $\lim \varphi(X_n) = 0$ for any sequence of disjoint sets $X_n \subseteq X \in R$. It is pointed out that if the whole set of preceding conditions is admitted, this last condition is sufficient and necessary for boundedness of φ. These results are used to derive known theorems. *E. Baiada* (Modena)

Santagati, Giuseppe 4854

Sopra un teorema della teoria del prolungamento di misure.
Matematiche (Catania) **18** (1963), 73–82.

Two dual theorems on extension of measures due to U. Barbuti [Ricerche Mat. 8 (1959), 145–162; MR **23** #A3223] were proved again by G. Letta [ibid. 8 (1959), 300–319; MR **23** #A3224] by making use of a rather deep lemma of Carathéodory. The proofs exhibited here do not use this lemma. *E. Baiada* (Modena)

Leslie, Joshua 4855

Sur l'intégration dans les groupes de Whitehead gradués.
C. R. Acad. Sci. Paris **259** (1964), 34–37.

Let $X = \bigcup X_n$ be the strict inductive limit of an increasing sequence of compact metric spaces X_n, each of finite dimension. If $\dim(X_i) \leq n_i$, there exists a topological structure $\mathfrak{M}$ on X less fine than the initial structure, and a distance ρ compatible with $\mathfrak{M}$, such that the mth Hausdorff measure associated with ρ vanishes on X_i for every real number $m > n_i$. If X is also a topological group, and if $X_p \cdot X_q \subset X_{p+q}$ for all integers p and q, and $X_n^{-1} \subset X_n$, then X is called a graded group of Whitehead. Let $G = \bigcup G_n$ be such a group, with $\dim(G_i) = n_i$. Then there exists a sequence of left-invariant Borel measures M_i such that

(i) $M_j(G_k)=0$ for $n_k<j$; (ii) $M_j(G_k)>0$ for $n_k\geqq j$; and nontrivial in the sense that each is positive and finite for some Borel set. *J. C. Oxtoby* (Bryn Mawr, Pa.)

Gadžiev, A. D. 4856

On the speed of convergence of a class of singular integrals. (Russian. Azerbaijani summary)

Izv. Akad. Nauk Azerbaĭdžan. SSR Ser. Fiz.-Mat. Tehn. Nauk **1963**, *no.* 6, 27–31.

On dira que $\phi_\lambda(t,x)$ remplit la condition (A) si: (1) elle est négative et, pour λ et x fixes, est croissante sur $[a,x]$ et décroissante sur $[x,b]$; et si l'on a

$$\int_a^b \phi_\lambda(t,x)\,dt = 1,$$

(2) pour chaque $y\neq x$ et pour $\lambda\to\infty$, on a $\phi_\lambda(y;x)=O(\Delta_\lambda)$, où

$$\Delta_\lambda = \int_{x-\delta}^{x+\delta} |t-x|^{\alpha+1}\phi_\lambda(t,x)\,dt \qquad (\alpha>0)$$

et $\Delta_\lambda\to 0$ pour $\lambda\to\infty$. Posons

$$\gamma(t) = \frac{f(t)-f(x)}{t-x}-f'(x) \quad \text{pour } t\neq x,$$
$$= 0 \qquad\qquad \text{pour } t = x.$$

Théorème 1: Considérons l'intégrale singulière

$$(1) \qquad W_\lambda(x) = \int_a^b K_\lambda(t,x)\,df(t)$$

et supposons que $K_\lambda(t,x)$ satisfait la condition (A), tandis que f est une fonction bornée, telle que l'intégrale (1) existe pour une certaine valeur de x. Si pour cette x et pour $t\to x$ on a

$$\gamma(t) = o(|t-x|^{\alpha+1}),$$

où $\alpha>0$ est arbitraire, alors pour $\lambda\to\infty$ on a

$$|W_\lambda(x)-f'(x)| = o(\Delta_\lambda).$$

Théorème 3: Soit f une fonction bornée, assurant, pour une certaine valeur de x, l'existence de l'intégrale (1). Si, pour cette x, la dérivée à droite $f_+'(x)$ et la dérivée à gauche $f_-'(x)$ existent et sont finies, alors $\lim_{\lambda\to\infty} W_\lambda(x)=(f_+'(x)+f_-'(x))/2$. *S. Marcus* (Bucharest)

Mikusiński, J. 4857

Sur une définition de l'intégrale de Lebesgue.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 203–204.

It is well known that a function f on R^q is Lebesgue integrable if and only if there exist characteristic functions $\{f_n\}$ and numbers $\{\lambda_n\}$ such that (1) $f(x)=\sum\lambda_n f_n(x)$ for almost all x, and $\sum|\lambda_n|\int f_n<\infty$. The author proves that the sequences $\{f_n\}$, $\{\lambda_n\}$ can be so chosen that equality (1) holds for at least all x for which the series converges absolutely. *M. Esser* (Dayton, Ohio)

Flett, T. M. 4858

On transformations in R^n and a theorem of Sard.

Amer. Math. Monthly 71 (1964), 623–629.

An elementary proof is given of the theorem that if D is open in R^n, f a continuously differentiable mapping of D into R^n, and $J(x)$ the Jacobian of f at x, then the image $f(E)$ of any measurable subset E of D is measurable and of measure at most the integral of $|J(x)|$ over E. The proof is based on a simple geometric inequality independent of whether $J(x)$ is zero on a subset of D or not. The formula for change of variables in a multiple integral follows then easily from this theorem. Another elementary proof of the same theorem is due to J. Mařík [Czechoslovak Math. J. **6** (81) (1956), 212–216; MR **18**, 880]. *A. C. Zaanen* (Leiden)

Kellerer, Hans G. 4859

Schnittmass-Funktionen in mehrfachen Produkträumen.

Math. Ann. **155** (1964), 369–391.

From the author's introduction: "Let (M,K,μ) be the product of the σ-finite measure spaces $(M_1,K_1,\mu_1),\cdots,(M_n,K_n,\mu_n)$. We can formulate the following "bisection problem": Can every set A in K be decomposed into two disjoint subsets A^1, A^2 in K such that, for each $i=1,\cdots,n$, $\mu_i(A_x^1)=\mu_i(A_x^2)$ for $(\prod_{k\neq i}\mu_k)$-almost all x in $\prod_{k\neq i}M_i$? (Here $A_x^j=\{y\in M_i|(x_1,\cdots,x_{i-1},y,x_{i+1},\cdots,x_n)\in A^j\}$.) Obviously the μ_i must be assumed to be atomless. In that case the question was answered affirmatively for $n=2$ in an earlier paper of the author [same Ann. **146** (1962), 103–128; MR **26** #5117]. Indeed, a more general result was proved there for $n=2$, namely: Given K-measurable functions $0\leq f\leq g$, there exists a set A in K such that, for each $i=1,\cdots,n$,

$$\int_{M_i} f\,d\mu_i = \int_{M_i}\chi_A g\,d\mu_i$$

$(\prod_{k\neq i}\mu_k)$-almost everywhere.

"In § 1 of this paper the preceding result is proved for arbitrary n. § 2 investigates what can be said when one drops the assumption that the μ_i are atomless. This enables one to study the totality of the 'cross-sectional measure functions' (Schnittmass-Funktionen) of sets A in K. If $T_1,\cdots,T_l$ are arbitrary subsets of $\{1,\cdots,n\}$, a criterion is given in § 3 for given functions $f_{T_1},\cdots,f_{T_l}$ to be cross-sectional measure functions for some subset A in K; indeed, one can even impose an auxiliary condition $A\subset A_0$ $(A_0\in K)$. In § 4 the author looks briefly at the problem of generalizing these results to infinite products. Finally, in § 5, the results are applied to the following 'marginal problem': What conditions must be satisfied by the bounded general measures $\nu_{T_k}|K_{T_k}$ $(1\leq k\leq l)$, and measures $\underline{\nu}\leq\bar{\nu}$ on K, so that there should exist a general measure $\nu|K$ with the following properties:

$$\nu^{T_k} = \nu_{T_k} \quad \text{for } k=1,\cdots,l, \qquad \underline{\nu}\leq\nu\leq\bar{\nu}.$$

(Here ν^{T_k} is the cross-sectional measure corresponding to the measure ν and the set T_k of components of the measure product.)" *J. M. G. Fell* (Seattle, Wash.)

Villegas, C. 4860

On qualitative probability σ-algebras.

Ann. Math. Statist. **35** (1964), 1787–1796.

According to the author, the first clear and precise statement of the axioms of qualitative probability was given by de Finetti. He further states that a more detailed treatment was given later by Koopman and that de Finetti and Koopman derived a probability measure from a qualitative probability under the assumption that, for any integer n, there are n mutually exclusive, equally probable events. L. J. Savage has shown, again according to the author,

that this strong assumption is unnecessary, proving that if a qualitative probability is only fine and tight, then there is one and only one probability measure compatible with it.

The author feels that since no property equivalent to countable additivity has been used as yet in the development of qualitative probability theory, and that since the concept of countable additivity is of such fundamental importance in measure theory, it is to be expected that an equivalent property would be of interest in qualitative probability theory, and that, in particular, it would simplify the proof of the existence of compatible probability measures.

Such a property is introduced in this paper, under the name of monotone continuity. It is shown that if a qualitative probability is atomless and monotonely continuous, then there is one and only one probability measure compatible with it, and this probability measure is countably additive. It is also proved that any fine and tight qualitative probability can be extended to a monotonely continuous qualitative probability, and therefore, contrary to what might be expected, there is no loss in generality if we consider only qualitative probabilities which are monotonely continuous.

The author states that at the present time there is still a controversy over the interpretation which should be given to the word probability in the scientific and technical literature. Although the author subscribes to the opinion that this interpretation may be different in different contexts, in this paper he does not enter into this controversy. *R. V. Chacon* (Columbus, Ohio)

Ito, Yuji 4863

Finite invariant measures for temporally homogeneous Markov processes.

Ergodic Theory (Proc. Internat. Sympos., Tulane Univ., New Orleans, La., 1961), *pp.* 151–172. *Academic Press, New York,* 1963.

Let $P(x, B)$ be the transition probability of a temporally homogeneous Markov process defined on a measure space $(X, \mathscr{B}, m)$. A measure ν is said to be invariant under $P(x, B)$ if $\int_X P(x, B)\nu(dx) = \nu(B)$ for every $B \in \mathscr{B}$.

The author discusses necessary and sufficient conditions for the existence of a finite measure ν which is invariant under $P(x, B)$ and is equivalent to m. This paper contains the main results and an outline of the proofs. A detailed exposition with complete proofs appears in Trans. Amer. Math. Soc. **110** (1964), 152–184 [MR **28** #1276].

A. Hajian (Boston, Mass.)

R.-Salinas, Baltasar 4864

[Rodríguez-Salinas, Baltasar]

The extension problem. (Spanish. English summary)

Ann. Mat. Pura Appl. (4) **64** (1964), 133–189.

Let G be a transformation group operating on a set E, and let $\mathscr{S}_0$ be a ring of subsets S of E. The article deals with a finite measure μ_0 (author's Spanish: "extensión") defined on $\mathscr{S}_0$. The measure $\bar{\mu}_0$ is an ultracompletion of μ_0 if $\bar{\mu}_0$ is an extension ("prolongación") of μ_0 to the class $\mathscr{S}$ of all subsets of every S in $\mathscr{S}_0$. If $\bar{\mu}_0 = \mu_0$, μ_0 is called an ultracomplete measure. A measure μ is said to be k-compatible with G if its domain is invariant under G and there exists a real-valued function k, defined on G, such that $\mu(\alpha S) = k(\alpha)\mu(S)$ for every $\alpha \in G$ and S in the domain of μ (if $k \equiv 1$, μ is invariant under G). G is a measurable group if there exists a measure μ^* defined on the algebra of all subsets of G, such that $\mu^*(G) = 1$ and μ^* is invariant under the group of left translations of G.

The author investigates the following oscillation functions: (1) $\omega(\mu, G) = \sup\{\mu(\alpha S) - \mu(S) \mid \alpha \in G, S \subset E\}$, where μ is an ultracomplete measure with $\mu(E) = 1$; (2) $\omega(E, G) = \inf\{\omega(\mu, G) \mid \mu \in M\}$, where M is the set of all ultracomplete measures μ with $\mu(E) = 1$; (3) $\omega_0(\bar{\mu}_0, G) = \sup\{\bar{\mu}_0(\alpha S)/\mu_e(\alpha S) - \bar{\mu}_0(S)/\mu_e(S) \mid \alpha \in G, S \subset E\}$, where μ_e is the outer measure on $\mathscr{S}$ formed in the usual way from a given measure μ_0 k-compatible with G and not identically zero on $\mathscr{S}_0$, $\bar{\mu}_0$ is an ultracompletion of μ_0, and $\mu_e(S) \neq 0$; (4) $\omega_0(G) = \inf\{\omega_0(\bar{\mu}_0, G) \mid \bar{\mu}_0 \in M_0\}$, where M_0 is the set of all ultracompletions of μ_0. The main results are the following. (1) Necessary and sufficient condition for the existence of an ultracomplete invariant (with respect to G) measure μ on $\mathscr{S}$ with $\mu(E) = 1$: $\omega(E, G) = 0$. (2) Necessary and sufficient condition for the existence of a k-compatible ultracompletion of a given k-compatible measure μ_0 defined on $\mathscr{S}_0$: $\omega_0(G) = 0$. Specifically, this ultracompletion exists if G is a measurable group.

Instances are established in which these conditions are or are not verified, and the results are applied to transformations of Euclidean, elliptic, hyperbolic, and affine spaces, leading, in the first case, to conclusions of Banach and Hausdorff on the existence of invariant ultracompletions related to Lebesgue measure in E_1 and E_2 and their non-existence in E_n if $n \geq 3$.

Zitarosa, Antonio 4865

Sull'esistenza di una misura invariante.

Ricerche Mat. **13** (1964), 106–117.

Let S be a set, $\mathscr{A}$ a relatively $\cup$-normal lattice of subsets of S, τ a one-to-one mapping of S onto S such that τ and

τ^{-1} are $\mathscr{A}$-measurable, $\mathscr{B}(\mathscr{A})$ the least relatively complemented and countably $\cap$-complete lattice containing $\mathscr{A}$. Main result: There exists an invariant (with respect to τ) non-null measure on $\mathscr{B}(\mathscr{A})$ if and only if there exists an $\mathscr{A}$-compact set $C \in \mathscr{B}(\mathscr{A})$ and a positive, finite, finitely additive set function β defined on $\mathscr{B}(\mathscr{A})$, such that $\lim'' n^{-1} \sum_{k=1}^{n} \beta(\tau^{-k}(C)) > 0$. (A set $C \subset T$ is $\mathscr{A}$-compact if every countable cover of C by sets of $\mathscr{A}$ contains a finite cover of C.) This is an extension of a result of U. Barbuti [Ann. Scuola Norm. Sup. Pisa (3) **15** (1961), 105–114; MR **23** #A3823]. Then there are derived some generalisations of a theorem of Krylov and Bogoljubov [Ann. of Math. (2) **38** (1937), 65–113] and a theorem of Oxtoby and Ulam [ibid. (2) **40** (1939), 560–566; MR **1**, 18].

Dževaršeĭšvili, A. G. 4869

On the existence of a singular integral. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **34** (1964), 529–534.

Let Γ be a simple closed curve, and let $S(t_1, t_2)$ denote the shortest arc length on Γ connecting points with parameter values t_1 and t_2. If the curve Γ satisfies the condition $S(t_1, t_2) \leq K|t_1 - t_2|$ and one other condition too lengthy to state here, then the author shows that the singular integral

$$S(f, t_0) = \lim_{\varepsilon \to 0} \frac{1}{\pi i} \int_{\Gamma_\varepsilon} \frac{f(t)\,dt}{t - t_0}$$

exists for almost all $t_0 \in \Gamma$ if $f \in L_1(\Gamma)$. Here Γ_ε denotes Γ with a suitably small section around t_0 cut out.

H. S. Wilf (Philadelphia, Pa.)

Perevalov, G. E. 4870

An analytic expression for the linear measure of a planar connected set. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 626–638.

The author extends to an arbitrary plane continuum K of finite Carathéodory length the classical formula expressing the length of a non-parametric Lipschitzian curve as the integral of $(1+y'^2)^{1/2}$. Here K need not be a countable sum of simple arcs; nevertheless, by making $y(x)$ many-valued, with K as its graph, and by replacing the integrand by a corresponding sum involving derivatives of various "branches", he obtains the desired formula, provided the axes are first rotated, if necessary. (It is a question of avoiding at most countably many such rotations; otherwise, the formula must be replaced by an inequality.) The formula applies equally to any plane connected set of finite length, but the length is then unaltered by passing to the closure, which is again a plane continuum.

L. C. Young (Madison, Wis.)

Mookhopadhyaya, A. K. 4871

On transformation of measurable sets.

Indian J. Mech. Math. **2** (1964), 21–23.

Let $P \subset E^n$ be a set of strictly positive Lebesgue measure in an n-dimensional Euclidean space and let $T_1, \cdots, T_t$ be a set of linear transformations, viz.,

$$T_k: x_i' = \sum_{j=1}^{n} \alpha_k a_{ij}^k x_j \qquad (i = 1, \cdots, n;\ k = 1, \cdots, t),$$

where $0 < |\alpha_k| \leq 1$ and (a_{ij}^k) is orthogonal. If x_0 is a point of density of the set P, then there are two spheres $K(x_0, r')$ and $K(x, r)$ such that (i) $K(x_0, r') \subseteq K(x, r)$, and (ii) for every $x \in K(x_0, r')$ there are vectors $h(x)$ such that to each $h(x)$ there correspond vectors $a_k(x) \in P \cap K(x_0, r)$ satisfying $a_k(x) = x + T_k h(x)$ $(k = 1, \cdots, t)$.

The above theorem was proved by the reviewer [J. Math. Soc. Japan **13** (1961), 13–19; MR **24** #A1988] in the case in which all (a_{ij}^k) are equal to the unit matrix. The proof of the present author is different from that of the reviewer and seems to be shorter. It is not difficult to see that the conclusion of the above theorem holds if T_k are any regular linear operators, finite in number. Besides this result, there are two more theorems, one of which is an application of the above theorem. *S. Kurepa* (Zagreb)

Young, L. C. 4872

Some extremal questions for simplicial complexes. V. The relative area of a Klein bottle.

Rend. Circ. Mat. Palermo (2) **12** (1963), 257–274.

Part IV, by W. H. Fleming and the author, appeared in same Rend. (2) **12** (1963), 200–210 [MR **29** #5987]. For

a given oriented $(k-1)$-dimensional polytopic cycle C in E^n, $1<k<n-1$, and for each positive integer m, let a_m denote the infimum of $|V|$ for all oriented polytopes V having mC as boundary. Here, $|V|$ means the area of V. The author produces an example of a 1-dimensional cycle C for which $a_2 < 2a_1$, the significant point being that strict inequality occurs. The relevance of this example lies in the fact that a variational algorithm of the author [Riv. Mat. Univ. Parma 5 (1954), 255–268; MR 18, 402] cannot solve the least area problem for integral currents as formulated by Federer and Fleming [Ann. of Math. (2) 72 (1960), 458–520; MR 23 #A588]. A similar example has been produced by Almgren [Topology 1 (1962), 257–299; MR 26 #4355].

W. P. Ziemer (Bloomington, Ind.)

Young, L. C. 4873

Generalized varieties as limits.

J. Math. Mech. 13 (1964), 673–692.

To treat higher-dimensional variational problems, the author has enlarged the class of parametric varieties to obtain a class of generalized varieties with satisfactory compactness properties, in a way similar to his generalized surfaces [see the author, Mem. Amer. Math. Soc. No. 17 (1955); MR 19, 559; J. Math. Mech. 11 (1962), 615–646; MR 25 #5162]. A similar enlargement is in the basis of the theory of normal and integral currents [see H. Federer and W. H. Fleming, Ann. of Math. (2) 72 (1960), 458–520; MR 23 #A588]. Those enlargements correspond, in a certain sense, to generalizations of the notion of polytope with positive real or integer coefficients, respectively. In this paper, two classes of generalized varieties, occurring in applications of the theories of L. C. Young and of H. Federer and W. H. Fleming, are characterized as similar closures of convenient classes of simplicial varieties (see Theorems A and B below).

A generalized variety L is a non-negative linear functional in the class of k-integrands, i.e., real-valued continuous functions $f(x, J)$, $x \in R^n$, where J is a k-vector of R^n with the homogeneity condition $f(x, \lambda J) = \lambda f(x, J)$, $\lambda \geq 0$. Track, boundary or pattern of L stands, respectively, for the restriction of L to integrands that are linear, exact and of the form $f(J)$. A generalized variety has a track (or boundary) A or B when its track (or boundary) coincides with that of a mixed σ-variety or σ-variety, respectively (i.e., varieties expressible as a finite, or countable, sum of Lipschitzian varieties with positive real or integer coefficients, respectively). A micro-variety at x is a generalized variety whose support is the single point x. The micro-pattern of L at x is the pattern of its microvariety at x. A generalized variety B is a generalized variety with track B. A pattern P has a resultant (B, m) if $P = \lim P_n$, where P_n are patterns of polytopes, each with the same boundary as the mth multiple of a simplex. A generalized variety B has at x a micro-resultant B if it has a micro-pattern with a resultant (B, m), where m is the local multiplicity $m(x)$.

A generalized variety is called admissible A if it has a boundary A, and admissible B if it is a generalized variety B and possesses at almost every x a micro-resultant B. Then, the main theorems of this paper are: Theorem A [B]: In order that L be a generalized variety admissible A [B], it is necessary and sufficient that there exist, for $n = 1, 2, \cdots$, a polytope L_n and a σ-polytope S_n both with positive real [integer] coefficients such that: (i) $\lim L_n = L$, (ii) $\lim S_n = 0$, (iii) $L_n + S_n$ has the same boundary as L.

The proof of Theorem A is based on techniques developed by W. H. Fleming and the author [Trans. Amer. Math. Soc. 76 (1954), 457–484; MR 16, 721], and in the proof of Theorem B conveniently modified results of the above-cited paper of H. Federer and W. H. Fleming are used.

Davis, Philip J. 4874

Triangle formulas in the complex plane.

Math. Comp. 18 (1964), 569–577.

The simplest triangle formula in the complex plane is as follows. Let T denote a triangle of vertices z_1, z_2, z_3, and let A be its area. If $f(z)$ is regular in the closure of T, then

$$\frac{1}{2A}\iint_T f''(z)\,dxdy = f(z_1, z_2, z_3),$$

where the right side denotes the second divided difference of $f(z)$. After discovering this relation, the author learned that it was found by T. Motzkin and the reviewer in 1952 [Proc. Amer. Math. Soc. 3 (1952), 517–526; MR 14, 157]. "The object of the present paper is to publicize this interesting formula, to give an alternate proof of it, and to derive a number of consequences and results related to the alternate approach." We cite one of the consequences: Let $z_1, \cdots, z_n$ designate the vertices in counter-clockwise order of a convex polygon P. Write $z_0 = z_n$, $z_1 = z_{n+1}$. Then, for all $f(z)$ regular in the closure of P

$$\iint_P f''(z)\,dz = 2\sum_{j=1}^{n} \frac{A(z_{j-1}, z_j, z_{j+1})}{(z_j - z_{j-1})(z_j - z_{j+1})} f(z_j),$$

where A is the area of the triangle having the vertices indicated.

[Ferentinou-Nicolacopoulou, Jeanne]

★Two new methods for the localization of zeros of polynomials in one variable. (Greek)

Thesis, Athens University, Athens, 1964. viii + 134 pp.

Both methods are based on the following theorem, which, although a simple corollary of well-known results, proves to be quite efficient. Let $f(x) = x^n + \sum_{j=1}^k a_j x^{n-n_j}$ with a_j, x complex, $n \geq n_j > 0$. Choose any real θ_j and non-negative real m_j; then any positive ξ such that $\sum_{j=1}^k m_j \xi^{\theta_j - n_j} \leq 1$ and $\xi^{\theta_j} m_j \geq |a_j|$ is an upper bound of the moduli of the roots of $f(x)$. In this theorem the exponents are not necessarily integers, in which case x^s is taken to be $\exp s[\log r + i(\varphi + 2K\pi)]$, where $x = re^{i\varphi}$, $0 \leq \varphi < 2\pi$, and K is some fixed integer; for positive x, however, we take $K = 0$ unless x^s appears in the polynomial whose roots are investigated.

The first part of this work consists of a systematic use of this theorem to compute various upper bounds. The freedom of choice of the θ_j and m_j leads to a huge collection of bounds, among which are included several obtained previously by others (e.g., Carmichael, Landau, Karamata, Kojima, Cowling and Thron) in the same, or sometimes in a weaker, form.

In the second part another method (a little too complicated to reproduce here) is developed, which consists essentially in reducing the problem to another involving a polynomial of fewer terms, so that by successive applications only two terms are left.

The volume ends with a collection of 117 formulas established in the text and an extensive bibliography.

P. C. Deliyannis (Chicago, Ill.)

Walsh, J. L.; Shisha, O. 4876

Extremal polynomials and the zeros of the derivative of a rational function.

Proc. Amer. Math. Soc. **15** (1964), 753–758.

Let m_j and n_j be positive integers and $N=\sum_1^m m_j-\sum_1^n n_k$. Let $R(z)=\prod_{j=1}^m (z-\alpha_j)^{m_j}\prod_{k=1}^n (z-\beta_k)^{-n_k}$ and $\omega(z)=\prod_{j=1}^m (z-\alpha_j)\prod_{k=1}^n (z-\beta_k)$. Let P be the class of polynomials $P(z)=Nz^{m+n-1}+a_1z^{m+n-2}+\cdots+a_{m+n-1}$, where the a_j are arbitrary, with $P(\alpha_j)=m_j\omega'(\alpha_j)$ for $j=1, 2, \cdots, m$. The authors establish as their principal theorem that the finite zeros of the derivative of R are the zeros of the polynomial of class P for which the weighted Tchebycheff norm, $\max|P(\beta_j)/n_j\omega'(\beta_j)|$, $j=1, 2, \cdots, n$, is a minimum. This theorem is analogous to the result due to Fekete and von Neumann when $R(z)$ is a polynomial. Together with the authors' previous results on restricted infrapolynomials, this theorem may be used to prove some well-known results of Bôcher and others on the location of the finite zeros of the derivative of a rational function.

{Reviewer's note: The results stated in the authors' remarks 1°, 2° and 3° are covered by the reviewer [*The geometry of the zeros of a polynomial in a complex variable*, p. 71, Amer. Math. Soc., New York, 1949; MR **11**, 101; ibid, p. 19; see also Trans. Amer. Math. Soc. **32** (1930), 81–109, p. 108 and Bull. Amer. Math. Soc. **42** (1936), 400–405, p. 401].}

M. Marden (Milwaukee, Wis.)

Rubinstein, Z.; Walsh, J. L. 4877

On the location of the zeros of a polynomial whose center of gravity is given.

J. Analyse Math. **12** (1964), 129–142.

In recent papers [J. Math. Pures Appl. (to appear); Proc. Amer. Math. Soc. **15** (1964), 354–360; MR **28** #4092; also #4876 above] Walsh and others established some new coincidence theorems regarding points in a unit circle. For example, if $m_k>0$ and $|\alpha_k|\leqq r$ for all k, and if $|z|>r$ and $\sum_{j=1}^n m_j\alpha_j{}^k=0$ for $k=1, 2, \cdots, p$, then the point α defined by the equation $\sum_{k=1}^n m_k(z-\alpha_k)^{-1}=\sum_{k=1}^n m_k(z-\alpha)^{-1}$ satisfies the inequality $|\alpha|\leqq r^{p+1}|z|^{-p}$. These lemmas are in the present paper applied further to yield theorems like the following. (I) Let the zeros $\alpha_1, \alpha_2, \cdots, \alpha_n$, the zeros of the nth degree polynomial f, satisfy the conditions $|\alpha_j|\leq 1$ and $\sum_{i=1}^n \alpha_i{}^k=0$ for $j=1, 2, \cdots, n$; $k=1, 2, \cdots, p$. If g_1 and g_2 are arbitrary functions and if z with $|z|>1$ is a zero of $h(z)=g_1(z)f(z)-g_2(z)f'(z)$, then $|z^p(z-ng_2/g_1)|\leq 1$. (II) Let $f(z)=a_mz^m+a_{m-p}z^{m-p}+\cdots+a_sz^s+a_0$, $p\geqq 1$, $s\geqq 1$; $g(z)=\sum_0^n b_kz^k$; $h(z)=\sum_0^m a_kg(k)z^k$. If all the zeros of f lie in the ring $0\leqq r_1\leqq |z|\leqq r_2\leqq\infty$ and those of g in the region $0\leq \rho_1\leq |z/(z-m)|\leq \rho_2\leqq\infty$, then all the zeros of h lie in the ring

$$r_1\min(1, \rho_1{}^{n/s}) \leqq |z| \leqq r_2\max(1, \rho_2{}^{n/p}).$$

In the case $p=0$, (I) reduces to a result implied by the reviewer [Bull. Amer. Math. Soc. **42** (1936), 400–406], and in the case $p=s=1$, (II) reduces to a result of the reviewer [*The geometry of the zeros of a polynomial in a complex variable*, Amer. Math. Soc., New York, 1949; MR **11**, 101].

M. Marden (Milwaukee, Wis.)

Tonkov, T. T. 4878

A bound for the moduli of zeros of polynomials. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 748–749.

It follows from a theorem of J. L. Walsh [Trans. Amer. Math. Soc. **24** (1922), 163–180] that the moduli of the zeros of the polynomial $f(z)=z^n+a_1z^{n-1}+\cdots+a_n$ are bounded above by

$$|a_n|^{1/n}+|a_{n-1}|^{1/(n-1)}+\cdots+|a_2|^{1/2}+|a_1|.$$

The author gives a simple proof of this fact and also finds a lower bound for any z such that $f(z)=0$, namely,

$$|a_n|^{1/n}-|a_{n-1}|^{1/(n-1)}-\cdots-|a_2|^{1/2}-|a_1| \leq z.$$

Viten'ko, I. V.; Kostovskiĭ, A. N. 4879

Determination of principal indices of Laurent series. (Russian)

Dokl. Akad. Nauk SSSR **155** (1964), 732–734.

If $f(z)$ is given by a convergent Laurent series in the annulus $r<|z|<R$, if $r<x<R$, and if $f(z)\neq 0$ for $|z|=x$, then the principal index of the given series is

$$I(x) = \frac{1}{2\pi i}\int_{|z|=x}\frac{f'(z)}{f(z)}\,dz.$$

The authors establish certain conditions for the existence of $I(x)$ for a given series. The conditions involve the size of the coefficients of the series for $\prod_\omega f(\omega z^{1/k})$, where ω runs through the kth roots of unity.

H. S. Wilf (Philadelphia, Pa.)

Dickson, D. G. 4880

Analytic mean periodic functions.

Trans. Amer. Math. Soc. **110** (1964), 361–374.

Soient μ une mesure à support compact dans le plan complexe, $f(z)=\int\exp(zw)d\mu(w)$, P le diagramme conjugué de f (=l'intersection des supports convexes des mesures μ' telle que $f(z)=\int\exp(zw)d\mu'(w)$), R un ouvert du plan complexe. Une fonction φ, analytique dans $R+P$ et solution dans R de l'équation (1) $\int\varphi(z+w)d\mu(w)=0$, est dite moyenne-périodique dans R par rapport à f; on note $\varphi(z)\in K$, et on munit l'espace vectoriel K de la topologie de la convergence compacte. Le problème principal est de donner des conditions garantissant que les exponentielles monômes (2) $z^h\exp(\zeta z)\in K$ forment un système total dans K; des réponses partielles ont été données par L. Schwartz [Ann. of Math. (2) **48** (1947), 857–929; MR **9**, 428], A. Leont'ev [Uspehi Mat. Nauk **11** (1956), no. 5 (71), 26–37; MR **18**, 728] et le rapporteur [*Lectures on mean periodic functions*, Tata Inst. Fundamental Res., Bombay, 1959]. Etant donné $\tau>0$ et β complexe, l'auteur dit qu'une suite de contours emboités Γ_p ($p=1, 2, \cdots$) est (τ, β) associée à f si (I) Γ_p est contenu dans $r_p\leq |z|\leq Cr_p$ (C constante, $r_p\to\infty$) et $\log\lambda_p=o(r_p)$, λ_p étant la longueur de Γ_p, (II) pour tout $\varepsilon>0$, $|f(z)\exp(-\beta z)|>\exp(-(\tau+\varepsilon)r_p)$ quand $z\in\Gamma_p$, p assez grand. Comme conséquences de théorèmes

de représentation de $\varphi \in K$ par des séries d'exponentielles polynômes (2), sous diverses conditions, l'auteur montre que K est engendré par les exponentielles polynômes dès que, pour tout $\beta \in P$, il existe des contours $(0, \beta)$ associés à f. Des conditions pour qu'il en soit ainsi sont ensuite données, ainsi que des théorèmes d'unicité affirmant que le développement de φ en exponentielles polynômes (2) ne dépend pas de f. *J.-P. Kahane* (Orsay)

Besicovitch, A. S. 4881

On analytic functions.

Math. Gaz. **48** (1964), 270.

Let f and g be two general (multiple-valued) analytic functions. Suppose that for each z in a domain D the set of values of f is the same as the set of values of g. Then f and g are the same analytic function, i.e., are obtainable by analytic continuation from some common initial element. *R. P. Boas, Jr.* (Evanston, Ill.)

Distler, Raymond J. 4882

The domain of univalence of certain classes of meromorphic functions.

Proc. Amer. Math. Soc. **15** (1964), 923–928.

Let K be a non-empty closed subset of the complex plane, and let $U(K)$ denote the set of all points P in the plane such that K "subtends an angle less than $\pi/2$". Let $F(K)$ denote the family of functions of the form

$$f(z) = \sum_{k=1}^{n} \frac{A_k}{(z-a_k)}, \qquad A_k > 0,$$

where the a_k are points of K. Then the author's main result is the following. If $U(K)$ is not empty, then each member of $F(K)$ is univalent in $U(K)$; moreover, if D is a different domain such that $U(K) \subset D$, then there is a function in $F(K)$ that is not univalent in D. This result generalizes one due to Čakalov [C. R. Acad. Sci. Paris **242** (1956), 437–439; MR **17**, 724], and it is related to results due to the reviewer [Michigan Math. J. **5** (1958), 91–94; MR **20** #2453] and Cowling and Royster [J. Math. Soc. Japan **13** (1961), 104–108; MR **23** #A3838]. *M. Reade* (Ann Arbor, Mich.)

Pommerenke, Ch. 4883

Lacunary power series and univalent functions.

Michigan Math. J. **11** (1964), 219–223.

The author proves the following theorem. If

$$f(z) = a_0 + \sum_{k=1}^{\infty} (a_{n_k-p} z^{n_k-p} + \cdots + a_{n_k} z^{n_k})$$

is analytic and different from zero in $|z| < 1$, where p is a fixed non-negative integer and $n_{k+1}/n_k > \lambda > 1$ $(k \geq 1)$, then for $0 \leq q \leq p$, $a_{n_k-q} \to 0$ $(k \to \infty)$.

It is shown, using a result essentially due to Fejér and Fekete, that if $f(z) \neq 0$ $(|z| < 1)$, then there is an associated sequence of polynomials which do not vanish in $|z| < 1$. Hence it is proved that the assumption that the theorem is false leads to a contradiction. The proof is not difficult, but it is very ingenious.

The paper concludes with two applications. One is to functions analytic in $|z| < 1$ with non-vanishing first derivative, and the other is to functions analytic in $|z| > 1$ with a simple pole at $z = \infty$ and non-vanishing first derivative. In both cases the functions are assumed to have associated lacunary series expansions. *J. Clunie* (London)

On the type of Riemann surfaces defined by the linear substitution group. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 853–857.

Definition: A covering surface over the extended plane is said to admit a modular end provided that there exists a separating cross-cut so that on one of the components of the complement of the cross-cut the projection map is equivalent to the projection map of a conformal universal covering of the extended plane punctured in q (≥ 3) distinct points restricted to a component of the domain less a cross-cut joining two distinct logarithmic singularities. Theorem: A covering surface over the extended plane admitting a modular end is hyperbolic. *M. H. Heins* (Urbana, Ill.)

Kuramochi, Zenjiro 4886

Potentials on Riemann surfaces.

J. Fac. Sci. Hokkaido Univ. Ser. I **16**, 5–79 (1962).

The author begins with the statement: "The purpose of the present paper is to simplify and to extend almost all theorems contained in previous papers." He refers to Osaka Math. J. **8** (1956), 119–137 [MR **18**, 120]; ibid. **8** (1956), 145–186 [MR **19**, 23]; ibid. **10** (1958), 119–136 [MR **20** #3271]; Proc. Japan Acad. **36** (1960), 118–122 [MR **22** #11121]. Actually, there are many improvements, both in proofs and results. However, there remain some non-trivial ambiguities in his theory. The main criticism lies in the lack of a rigorous statement and a proof of the Dirichlet principle.

Let R be an open Riemann surface and let an open "disk" R_0 be excluded from R. First, various kinds of harmonic functions are introduced on subdomains of $R - \bar{R}_0$. One of them is the function $N(p, q)$ which is a harmonic function of p in $R - \bar{R}_0$ outside of a positive logarithmic pole at a point q, vanishes on the boundary ∂R_0, and has a minimum Dirichlet integral in a neighborhood of the ideal boundary of R. This function plays a rôle similar to that of $K(p, q) = G(p, q)/G(p, q_0)$ in the theory of the Martin boundary, where G is a Green's function. Thus, the so-called Kuramochi boundary B is defined. Next, a positive superharmonic function U in $R - \bar{R}_0$ is called $\bar{\text{s}}$uperharmonic if ${}_DU \leq U$ in $R - \bar{R}_0 - \bar{D}$ for every relatively compact subdomain D of $R - \bar{R}_0$, where ${}_DU$ is, roughly speaking, the harmonic function in $R - \bar{R}_0 - \bar{D}$ which coincides with U on ∂D, which vanishes on ∂R_0, and which has a minimum Dirichlet integral in a neighborhood of the ideal boundary of R. Some properties of $\bar{\text{s}}$uperharmonic functions are proved and every $\bar{\text{s}}$uperharmonic function vanishing on ∂R_0 is represented by the potential with kernel $N(p, q)$ of a measure on $(R - \bar{R}_0) \cup B$. A function ${}_AU$, similar to a reduced function in the theory of the Martin boundary, is defined for any closed subset A of B. The set of points $p \in B$ with ${}_{(p)}(N(z, p)) = 0$ is denoted by B_0, and B_1 is defined by

$B - B_0$. It is proved that every potential $\int_B N d\mu$ can be written as $\int_{B_1} N d\mu_1$, and the latter measure μ_1 is called a canonical mass distribution. However, its uniqueness is not established. A harmonic superharmonic function U vanishing on ∂R_0 is called minimal if the $\overline{\text{s}}$uperharmonicity of V and $U - V$ implies that V is a constant multiple of U. The author proves that U is minimal if and only if it is a constant multiple of some $N(z, p)$ with $p \in B_1$. Up to this point, the discussions are parallel to those in the theory of the Martin boundary.

The author proceeds to determine at every point of B the value of any $\overline{\text{s}}$uperharmonic function U, vanishing on ∂R_0, as the limit of a certain kind of mean value of U. As a function on $(R - \bar{R}_0) \cup B$, U is seen to be lower semicontinuous. The local superharmonicity on B is defined and it is shown that U is locally superharmonic at each point of B_1. Finally, a maximum principle and the existence of an equilibrium potential are discussed.

The book of Constantinescu and Cornea [*Ideale Ränder Riemannscher Flächen*, Springer, Berlin, 1963; MR **28** #3151] gives proofs, often by different methods, to many results of the present paper. The part parallel to the theory of the Martin boundary will be made elementary, somewhat along the original line of Kuramochi, in a forthcoming paper of the reviewer. *M. Ohtsuka* (Hiroshima)

Ozawa, Mitsuru 4887

On the growth of analytic functions.

Kōdai Math. Sem. Rep. **16** (1964), 98–100.

The author continues his study of the distribution of values of meromorphic functions on Riemann surfaces [same Rep. **15** (1963), 245–256; MR **28** #5175; ibid. **16** (1964), 40–43; MR **29** #3630]. In contrast to the general theorems of L. Sario [Acta Math. **109** (1963), 1–10; MR **26** #2602], the emphasis here is placed on actual existence questions for functions with prescribed growth. Slow-growing functions are not subject to the main theorems of Sario.

The present paper presents two examples of surfaces tolerating no meromorphic functions of prescribed slow growth. Specifically, consider a plane E with slits S_i clustering only at ∞. By "sewing" two such planes together, a parabolic surface W is obtained, which, outside of a compact subset, has a natural holomorphic projection on the z-plane. In terms of it a characteristic function $T(|z|, f)$ can be defined for an f meromorphic on W. If $n(a, E)$ denotes the number of slits of E in $\{|z| < a\}$, then, for all nonconstant f,

$$\limsup T(r, f)/\log r \geq \limsup \log n(r, E)/\log r \quad \text{as } r \to \infty.$$

The second example is a hyperbolic surface with a similar property. *B. Rodin* (La Jolla, Calif.)

Ozawa, Mitsuru 4888

Remarks on unramified abelian covering surfaces of a closed Riemann surface.

Kōdai Math. Sem. Rep. **16** (1964), 101–104.

O_{MD} is the class of Riemann surfaces which cannot be realized over the Riemann sphere with finite spherical area; $O_{AB}{}^0$ consists of surfaces containing no subregion on which a nonconstant bounded analytic function exists whose real part vanishes continuously on the relative boundary. Let W be an unramified, unbounded, abelian covering surface of a closed surface R. A condition on the group Γ of cover transformations is given which implies that $W \in O_{AB}{}^0 \cap O_{MD}$. It is based on the results of T. Kuroda [Nagoya Math. J. **10** (1956), 27–50; MR **18**, 290] and A. Mori [J. Math. Soc. Japan **6** (1954), 162–176; MR **16**, 581]. If Γ is free abelian of rank r, then a characteristic function is defined on W in terms of which there is a meromorphic function of order r. *B. Rodin* (La Jolla, Calif.)

Ahlfors, Lars V. 4889

Extension of quasiconformal mappings from two to three dimensions.

Proc. Nat. Acad. Sci. U.S.A. **51** (1964), 768–771.

The reviewer has shown that if f is a quasiconformal mapping of the 3-dimensional half-space $x_3 > 0$ onto itself, then f induces a quasiconformal mapping φ of the boundary plane $x_3 = 0$ onto itself [Trans. Amer. Math. Soc. **103** (1962), 353–393; MR **25** #3166]. In the present important paper, the author shows conversely that if φ is a quasiconformal mapping of the plane $x_3 = 0$ onto itself, then there exists a quasiconformal mapping f of the half-space $x_3 > 0$ onto itself which has φ as its induced boundary correspondence. Thus one obtains a characterization for the boundary correspondences, induced by quasiconformal mappings of a 3-dimensional half-space onto itself, similar to that obtained in two dimensions by Beurling and Ahlfors [Acta Math. **96** (1956), 125–142; MR **19**, 258]. To prove his extension theorem, the author first observes that, since an arbitrary plane quasiconformal mapping can be expressed as the composition of mappings with dilatation arbitrarily close to 1, it is sufficient to show that mappings φ with small dilatation can be extended. Next, given a φ with sufficiently small dilatation, he constructs for each integer N a piecewise linear homeomorphism f_N of $x_3 \geq 0$ onto itself such that $f_N(x) = \varphi(x)$ for $x = (m/N, n/N, 0)$, where m and n are integers, and such that the dilatation of f_N does not exceed a fixed bound. Then a subsequence of $\{f_N\}$ converges to a homeomorphism f of $x_3 \geq 0$ onto itself which is quasiconformal in $x_3 > 0$ and agrees with φ in $x_3 = 0$. *F. W. Gehring* (Cambridge, Mass.)

Ahlfors, Lars V. 4890

Finitely generated Kleinian groups.

Amer. J. Math. **86** (1964), 413–429.

Let Γ denote a group of Möbius transformations A acting on the extended plane. By Σ is meant the set of the accumulation points of the orbits of Γ. The set Σ is closed. When it contains at least three points but is not the extended plane, Γ is called a Kleinian group. The complement of Γ, denoted by $\Omega(\Gamma)$, is called the set of discontinuity. The quotient $S = \Omega/\Gamma$ has a natural complex structure which renders the projection map π taking a point of Ω into its orbit holomorphic. The components S_i of S are Riemann surfaces.

By $Q(\Gamma)$ is meant the space of holomorphic functions φ on Ω satisfying: $\varphi[A(z)][A'(z)]^2 = \varphi(z)$, $A \in \Gamma$, $\int_{\Omega/\Gamma} |\varphi|\, dx\,dy < +\infty$. Fixing $\varphi_0 \in Q(\Gamma)$, not identically zero, one introduces the Beltrami differentials $\nu = \varphi_0{}^{-1}|\varphi_0|\beta$, where β is bounded and measurable on Ω and automorphic with respect to Γ. By $N(\Gamma)$ is meant the set of ν satisfying $\int_{\Omega/\Gamma} \varphi\nu\, dx\,dy = 0$ for all $\varphi \in Q(\Gamma)$. Given a Beltrami differential ν, one introduces

$$f(\zeta) = -\pi^{-1} \int_\Omega \nu(z) \left[\frac{1}{z - \zeta} - \frac{\zeta}{z - 1} - \frac{1 - \zeta}{z}\right] dx\,dy.$$

It is shown that if Γ is finitely generated, then $Q(\Gamma)$ is finite-dimensional. The basic lemmas are: (1) $\nu \in N(\Gamma)$ if and only if $f=0$ on Σ; (2) $\nu \in N(\Gamma)$ if and only if $f[A(z)] = f(z)A'(z)$, $A \in \Gamma$.

Several unsolved problems are stated. One is: If Γ is finitely generated, does Σ have zero area?

The author points out that the proof of the principal theorem of the paper asserting the finitary character of S when Γ is finitely generated is incorrect and that the validity of the assertion remains unsettled. Theorem 6 remains valid in spite of a recurrence of the error of the proof just referred to, thanks to a result of R. Accola. On page 418, line 13, replace restriction by restrictions and on line 23 replace O by o.

Proximate order (R) of entire functions represented by Dirichlet series.

Collect. Math. **14** (1962), 275–278.

Let $f(s) = \sum_1^\infty a_n \exp(s\lambda_n)$, $0<\lambda_1<\cdots<\lambda_{n-1}<\lambda_n \to \infty$, $\liminf_{n\to\infty} (\lambda_n - \lambda_{n-1}) > 0$, be an entire function of order ρ $(0<\rho<\infty)$ and let $\rho(\sigma)$ such that $\lim_{\sigma\to\infty} \rho(\sigma) = \rho$ and $\lim_{\sigma\to\infty} \sigma\rho'(\sigma) = 0$ be a Ritt proximate order of $f(s)$ as defined by Sunyer Balaguer [Proc. Amer. Math. Soc. **4** (1953), 310–322; MR **14**, 738].

Then

$$\limsup_{\sigma\to\infty} \left(\log\left\{\sup_{-\infty<t<\infty} |f(\sigma+it)|\right\}\Big/\exp[\sigma\rho(\sigma)]\right) = A$$

if and only if $\limsup_{n\to\infty} \varphi(\lambda_n)|a_n|^{1/\lambda_n} = (A\rho e)^{1/\rho}$, where $\varphi(t)$ is defined as the solution of $t = \exp[\rho(\log\varphi)\log\varphi]$, $t>t_0$.

A. G. Azpeitia (Amherst, Mass.)

Wittich, H. 4895

Über eine Borelsche Identität.

Math. Z. **84** (1964), 233–243.

Let $a_0, a_1, \cdots, a_n; g_1, g_2, \cdots, g_n$ be entire functions satisfying the following conditions:

(i) $m(r, a_k) = o\left(\sum_{j=1}^n m(r, \exp(g_j))\right)$ $(k = 0, 1, \cdots, n)$,

where $m(r,f)$ denotes the mean of Nevanlinna of the function f; (ii) no g is constant. Then, an identity such as

$$\sum_{k=1}^n a_k(z)\exp(g_k(z)) \equiv a_0(z)$$

implies

$$\sum_{k=1}^n c_k a_k(z)\exp(g_k(z)) \equiv 0,$$

where the c's are constants, not all zero. The author proves this result and remarks that it is a sharpened form (using the notions of Nevanlinna's theory) of older results of E. Borel and P. Csillag. The paper contains also a study of the distribution of values of the entire transcendental solutions of a linear differential equation $L(w) = \sum_{j=0}^n a_j(z)w^{(n-j)} = 0$. The author shows that if w is an entire solution such that $m(r, a_j) = o(m(r, w))$ $(j = 0, 1, \cdots, n)$, if ϕ is an entire function such that $m(r,\phi) = o(m(r, w))$ and $L(\phi) \not\equiv 0$, then the zeros of $w - \phi$ are not deficient in the sense of Nevanlinna. He indicates a sharper form of this result in the special case of polynomial a's and considers also an extension of a result of Saxer [Math. Z. **17** (1923), 206–227].

On the deficiencies of a meromorphic function. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 1030–1033.

The author proves that for a meromorphic function $f(z)$ of finite lower order $\lambda > \frac{1}{2}$

$$\sum_a (\delta(a, f))^{1/2} < K\lambda^{1/2},$$

where K is an absolute constant. The same estimate is also valid if $\lambda < \frac{1}{2}$ and $f(z)$ has at least two deficient values. The example $f(z) = \int_0^z e^{-t^\lambda}\, dt$ ($\lambda = 1, 2, \cdots$) shows that the result is best possible as far as the dependence on λ is concerned. *W. H. J. Fuchs* (Ithaca, N.Y.)

Suvorov, G. D. 4898

A fundamental theorem on boundary correspondence for a sequence of topological mappings of class $\widetilde{BL}_k$ of plane regions. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 1152–1162.

A real-valued, continuous function f in a plane domain D of the finite xy-plane belongs to the class BL_k provided it has first-order generalized partial derivatives (in the sense of S. L. Sobolev) and

$$\iint_D [f_x^2 + f_y^2]\, dx dy \leqq k < \infty.$$

A mapping $T(z) = f_1(x, y) + if_2(x, y)$ of D belongs to the class $\widetilde{\mathrm{BL}}_k$ if on every open set D_m in D on which $|T(z)| < m$ the functions f_1 and f_2 belong to some class BL_k, and if, moreover,

$$\iint_{D_m} \frac{\sum_{j=1,2} \operatorname{grad}^2 f_j}{\left(1 + \sum_{j=1,2} f_j^2\right)^2}\, dx dy \leqq k.$$

The author's main result concerns a sequence of one-to-one homeomorphisms T_n of simply connected plane domains A_n onto plane domains B_n. Suppose the sequences $\{A_n\}$ and $\{B_n\}$ converge (in the sense of Carathéodory) to nondegenerate kernels A_0 and B_0, respectively; suppose all the T_n and T_n^{-1} belong to some class $\widetilde{\mathrm{BL}}_k$ (k independent of n) on their domains; finally, suppose that $\{T_n\}$ and $\{T_n^{-1}\}$ converge almost uniformly to mappings T_0 and T_0^{-1} between A_0 and B_0, and that $T_0, T_0^{-1} \in \widetilde{\mathrm{BL}}_k$. Then the sequence $\{T_n\}$ determines a one-to-one correspondence between prime ends of the sequences $\{A_n\}$ and $\{B_n\}$. *G. Piranian* (Ann Arbor, Mich.)

Simonenko, I. B. 4900

A maximal boundary property of functions with integral representations of a certain type. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1301–1302.

Let $\varphi(z)$ be an H_p function holomorphic in the unit circle C. At each point $t \in C$ as vertex is attached a sector S_t lying completely in C. Inspired by the work of Calderón and Zygmund [Acta Math. **88** (1952), 85–139; MR **14**, 637] the author extends a theorem of M. Riesz [Math. Z. **27** (1927), 218–244] concerning the norm $\|M\|_{L_p}$ of the function $M(t) = \sup_{z \in S_t} |\varphi(z)|$. The result is given without proof. *D. Mitrović* (Zagreb)

Zverovič, È. I. 4901

A boundary-value problem of Carleman type for multiply connected domains. (Russian)

Mat. Sb. (*N.S.*) **64** (**106**) (1964), 618–627.

Let D be a finite $(m+1)$-connected domain with Liapunov contour L, consisting of simple, closed curves $L_0, L_1, \cdots, L_m$, where L_0 encloses $L_1, \cdots, L_m$. Denote the complement of $D + L$ by D^-. Let $\alpha(t) = \sum_{k=0}^m \omega(t, L_k)\alpha_k(t)$, $t \in L$, where $\alpha_k(t)$ is an orientation-preserving homeomorphism of L_k into itself and $\omega(z, L_k)$ is the harmonic measure of L_k with respect to D. For $\alpha_k(t)$ it is assumed that $\alpha_k[\alpha_k(t)] \equiv t$ and that $\alpha_k'(t)$ is Hölder-continuous. For $G(t) \neq 0$ and Hölder-continuous on L the author considers the problem of determining a function $\Phi(z)$, single-valued and analytic in D, Hölder-continuous in $\bar{D}$, such that the following boundary relation holds: (*) $\Phi^+[\alpha(t)] = G(t)\overline{\Phi^+(t)}$. Denoting the number of linearly independent solutions of (*) by l and $\sum_{k=0}^m \kappa_k$ by κ, where $\kappa_k = \operatorname{ind} G(t)|_{L_k}$, the author shows that when $\kappa < 0$, $l = 0$; when $\kappa > 2m-2$, $l = \kappa - m + 1$; and when $0 \leqq \kappa \leqq 2m-2$, $\max\{0, \kappa - m + 1\} \leqq l \leqq 1 + [\kappa/2]$. *J. F. Heyda* (King of Prussia, Pa.)

Kaz'min, Ju. A. 4902

On a completeness criterion. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 549–556.

Let G be a simply connected domain lying in the finite part of the complex plane and bounded by a closed rectifiable curve Γ. Denote the space of functions regular in G with the topology of uniform convergence on compact sets by $A^-(G)$, and let $A^+(G)$ be its conjugate space (identified with a certain space of functions regular on Γ and outside G and vanishing at infinity). Let $\{h_n\}$ be a sequence of functions which is closed in $A^+(g)$, and let $f \in A^-(G)$. Define

$$f_n(z) = \frac{1}{2\pi i} \int_{C_n} \frac{f(t)h_n(t)}{t - z}\, dt, \qquad n = 0, 1, 2, \cdots,$$

where C_n is a Jordan curve lying in G such that h_n is regular on C_n and the domain exterior to it, and z is in the interior domain. The author shows that $\{f_n\}$ is complete in $A^-(G)$ if and only if f is not a rational function. He also applies this criterion to some specific sequences of functions. *H. H. Wicke* (Albuquerque, N.M.)

POTENTIAL THEORY

Calderón, A. P.; Zygmund, A. 4903

On higher gradients of harmonic functions.

Studia Math. **24** (1964), 211–226.

Let $U(x) = U(x_1, \cdots, x_n)$ be a real-valued harmonic function defined on a domain of n-dimensional Euclidean space E_n ($n \geq 2$). The authors prove that the pth power of

the norm of the gradient of order m of U, viz., $|\mathrm{grad}_m U| = [\sum_{|\alpha|=m} (D^\alpha U)^2(\alpha!)^{-1}]^{1/2}$, where $\mathrm{grad}_m U = (D^\alpha U)_{|\alpha|=m}$, $D^\alpha = (\partial/\partial x_1)^{\alpha_1} \cdots (\partial/\partial x_n)^{\alpha_n}$, $|\alpha| = \alpha_1 + \cdots + \alpha_n$, $\alpha! = \alpha_1! \cdots \alpha_n!$, is subharmonic for $p \geq (n-2)/(m+n-2)$. This generalizes a result of Stein and Weiss for $|\mathrm{grad}\, U|$ [Acta Math. **103** (1960), 25–62; MR **22** #12315]. A sufficient condition is given that a set of functions $(U_\alpha)_{|\alpha|=m}$, C^∞ in a sphere $|x| < R$, be the gradient of order m of a harmonic function. This result is applied to the set of functions $f_\beta(x, t) = R^\alpha P_t f$, f a real-valued function in $L^p(E_n)$, $p \geq 1$, $P_t f$ the Poisson integral of f and $R^\alpha = \prod R_j^{\alpha_j}$, R_j a Riesz transform and $\beta = (\alpha_1, \cdots, \alpha_n, k)$, $|\beta| = m$. The $f_\beta(x, t)$ are harmonic and $[\sum f_\beta^2(x, t)(\beta!)^{-1}]^{l/2}$ is subharmonic for $l \geq (n-1)/(m+n-1)$.

J. Mitchell (Madison, Wis.)

Položil, G. M. [Položil, G. N.] 4904

On the representation of p-harmonic functions by harmonic functions and their derivatives. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 1277–1280.

Suppose that $u(x, y)$ is a p-harmonic function with characteristic function $p(x, y)$ [see the author, Dokl. Akad. Nauk SSSR **58** (1947), 1275–1278; MR **9**, 507; ibid. **60** (1948), 769–772; MR **10**, 698]. The problem is to represent $u(x, y)$ in the form of a linear combination of a harmonic function $U(x, y)$ and its partial derivatives of nth order. A necessary and sufficient condition is given, which involves the characteristic function $p(x, y)$; this condition can be given explicitly whenever $n = 1, 2, 3$.

Ciesielski, Z. 4905

Brownian motion, capacitory potentials and semi-classical sets. I.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 265–270.

Let D be a domain in euclidean n-space $\mathbf{R}^n$ ($n \geq 2$) with a Green's function G and let K be a compact subset of D. We assume that G is normalized in the probabilistic sense, i.e., G is the potential-theoretic Green's function divided by half of the area of the unit sphere in $\mathbf{R}^n$. Let $W_K = G_{\mu_K}$ be the capacitory potential (of the capacitory distribution μ_K) of K with respect to this kernel G. Denote by $T_K(y)$ the total time spent in K by a Brownian path starting in $y \in D$ before reaching the boundary of D; denote by $U_K(y) = P[T_K(y) > 0]$ the probability that $T_K(y)$ is strictly positive. The set K is said to be semi-classical if $U_K = W_K$ on D (or, what amounts to the same, if $W_K(y) = U_K(y)$ for all $y \in D \setminus K$). In the case where the n-dimensional Lebesgue measure of K is > 0, different characterizations of a semi-classical set K are given. They are based on a modification of a method used by M. Kac [Proc. Second Berkeley Sympos. Math. Statist. and Prob. 1950, pp. 189–215, Univ. of California Press, Berkeley, Calif., 1951; MR **13**, 568] which consists in calculating the distribution of $T_K(y)$ by means of the eigenvalues λ_j and the eigenfunctions φ_j of the integral equation $\int_K G(x, y)\varphi(x)\,dx = \lambda\varphi(y)$ ($y \in K$). In particular, the following condition characterizes a semi-classical K:

$$W_K(y) = \lim_{t \to 0+} \sum_{j=1}^{\infty} e^{-t/\lambda_j} \frac{1}{\lambda_j} \int_K \varphi_j(x)\,dx \int_K G(x, y)\varphi_j(x)\,dx$$

for all $y \in D$. This generalizes a result of M. Kac ["Potential theory in three dimensions", Mimeographed notes, Rockefeller Institute, New York] proved for $n = 2, 3$ and for K with additional properties.

Integral representations of functions holomorphic in n-circular domains ("Continuation" of Szegő kernels). (Russian)

Mat. Sb. (N.S.) **65 (107)** (1964), 104–143.

The investigations in this paper are carried out only in the case $n = 2$. The author considers a full Reinhardt region D with boundary ∂D, and D^+ and ∂D^+ denote the traces of D and ∂D in the positive quadrant. For non-negative integers m, n the term $d_{mn}(D) = \sup_D |w^m z^n|$ is introduced. For non-negative real numbers (r, ρ) the set $\Delta(r, \rho) = \{(re^{i\theta_1}, \rho^{i\theta_2}) \mid 0 \leq \theta_\nu < 2\pi\}$ is introduced. Let μ denote a measure on ∂D^+ such that every open set is measurable.

The principal result is that a holomorphic function $h(\alpha, \beta) = \sum a_{mn}\alpha^m\beta^n$ can be used as the kernel in an integral formula

$$f(w, z) = \frac{1}{(2\pi i)^2} \int_{\partial D^+} d\mu$$

$$\times \int_{\Delta(|\zeta|, |\eta|)} f(\zeta, \eta) h\left(w\zeta \frac{\overline{\varphi_1(|\zeta|, |\eta|)}}{|\zeta|^2}, z\bar{\eta} \frac{\overline{\varphi_2(|\zeta|, |\eta|)}}{|\eta|^2}\right) \frac{d\zeta}{\zeta} \wedge \frac{d\eta}{\eta},$$

with bounded μ-measurable functions φ_1, φ_2 different from zero μ-almost everywhere on ∂D^+ if and only if φ_1 and φ_2 can be chosen as solutions to the momentum problem

$$a_{mn}^{-1} = \int_{\partial D^+} \varphi_1^m(|\zeta|, |\eta|)\varphi_2^n(|\zeta|, |\eta|)\,d\mu$$

subject to the condition

$$\limsup_{m+n \to \infty} \sqrt[m+n]{\left(|a_{mn}| d_{mn}(D) \sup_{\partial D^+} |\zeta|^{-m}|\eta|^{-n} \left|\varphi_1^m(|\zeta|, |\eta|)\varphi_2^n(|\zeta|, |\eta|)\right|\right)} \leq 1,$$

where sup is the effective supremum with respect to μ.

If the measure μ is given, it is possible to establish an integral formula

$$f(w, z) = \frac{1}{(2\pi i)^2} \int_{\partial D^+} d\mu \int_{\Delta(|\zeta|, |\eta|)} f(\zeta, \eta) h(w\bar{\zeta}, z\bar{\eta}) \frac{d\zeta}{\zeta} \wedge \frac{d\eta}{\eta},$$

where h is analytic, if and only if μ satisfies the condition that the effective supremum on ∂D^+ of $|\zeta|^m|\eta|^n$ with respect to μ is equal to the maximum on ∂D^+ of $|\zeta|^m|\eta|^n$ for every pair of non-negative integers m, n.

Integral formulae by Szegö, Bergman, Temljakov and others are special cases of the formulae derived in the present paper. *H. Tornehave* (Copenhagen)

Gross, Fred 4909

Entire functions all of whose derivatives are integral at the origin.

Duke Math. J. **31** (1964), 617–622.

An entire function f of two variables is strongly transcendental if no partial derivative of f is identically zero; it is a Hurwitz function if f and all its derivatives are integers at $(0, 0)$. Let $\varphi(r) = \max_n r^n/n!$, and let $\psi(r)$ be any increasing function that increases more rapidly than any power of r. The author extends results of Sato and Strauss [J. Math. Soc. Japan (to appear)] for the one-variable case. For example, a Hurwitz function whose maximum modulus satisfies (for large r_1, r_2) $M(r_1, r_2) < \varphi(r_1) + \varphi(r_2) + r_1^n + r_2^n$ must be a polynomial, but $r_1^n + r_2^n$ cannot be replaced by $\psi(r_1) + \psi(r_2)$. A Hurwitz function with $M(r_1, r_2)^2 < \varphi(r_1)^2\varphi(r_2)^2 + r_1^n r_2^n$ cannot be strongly transcendental, but it can be if $M(r_1, r_2) < \varphi(r_1)\varphi(r_2) + \psi(r_1)\psi(r_2)$. If f is a Hurwitz function with $M(r_1, r_2) < \varphi(r_1)\varphi(r_2) + r_1^n r_2^n$ and for each N there exist i, j, k, l with $k \geqq i > n$, $l \geqq j > N$, and $i < k$ or $j < l$, such that $\partial^{i+j}f/\partial z_1^i \partial z_2^j$ and $\partial^{k+l}f/\partial z_1^k \partial z_2^l$ are not zero at $(0, 0)$, then either $l/j > 4$ or $k/i > 4$ for large l and k.

R. P. Boas, Jr. (Evanston, Ill.)

Rényi, C. 4910

On some questions concerning lacunary power series of two variables.

Colloq. Math. **11** (1963/64), 165–171.

Let $f(z, w)$ be a transcendental entire function. If the power series of f from a point (a, b) arranged as a sum of homogeneous polynomials has the property that non-vanishing terms occur with frequency 0, the power series is called D-lacunary. The author proves that the power series of f from (a_1, b_1) and (a_2, b_2), where $a_1 \neq a_2$ and $b_1 \neq b_2$, will not be D-lacunary simultaneously except if f can be written in the form $\sum (w - \alpha z - \beta)P_n(z)$, where the factors P_n are polynomials. If the power series of f from (a, b) arranged as a power series in $w - b$ has the property that non-vanishing terms occur with frequency 0, the power series is called C-lacunary. If no partial derivative of f vanishes identically, the power series of f from (a_1, b_1) and (a_2, b_2), where $a_1 \neq a_2$, will not be C-lacunary simultaneously. If the planar frequency of non-vanishing terms of the power series measured with respect to rectangles [squares] is 0, the power series is called A-[A*-] lacunary. The author shows by examples that only much weaker results can hold in these cases.

Ronkin, L. I. 4911

On the conjugate orders and types of entire functions of several variables. **(Russian)**

Ukrain. Mat. Ž. **16** (1964), 408–413.

Let f be an entire function of n complex variables. Let B denote the set of points $(a_1, \cdots, a_n)$ of the positive cone of the n-dimensional real space for which $\log|f|$ is majorized asymptotically by $|z_1|^{a_1} + \cdots + |z_n|^{a_n}$. The boundary S of B is called the order surface of f. The author proves that the order surfaces of entire functions are characterized by the following two properties: (i) If $(a_1, \cdots, a_n) \in B$, then every point $(b_1, \cdots, b_n)$ where $b_j \geqq a_j$, $j = 1, \cdots, n$, belongs to B; (ii) The mapping $z_j \to z_j^{-1}$, $j = 1, \cdots, n$, maps B onto a convex region. For every point $(\rho_1, \cdots, \rho_n) \in S$ the set of points $(a_1, \cdots, a_n)$ of the positive cone of the n-dimensional real space for which $\log|f|$ is majorized by $a_1|z_1|^{\rho_1} + \cdots + a_n|z_n|^{\rho_n}$ is denoted B_ρ and its boundary is called the type surface of f corresponding to $(\rho_1, \cdots, \rho_n)$. The type surfaces are characterized by the properties that the complementary set of B_ρ is logarithmically convex, and that it, together with a point $(a_1, \cdots, a_n)$, contains every point $(b_1, \cdots, b_n)$, where $b_j \leqq a_j$, $j = 1, \cdots, n$. *H. Tornehave* (Copenhagen)

Forster, Otto; Ramspott, Karl Josef 4912

Über die Darstellung analytischer Mengen.

Bayer. Akad. Wiss. Math.-Natur. Kl. S.-B. **1963**, *Abt. II*, 89–99 (1964).

The following theorems are proved. (i) Let X be a holomorphically complete, reduced, n-dimensional complex space. Then, for every closed ideal a in the ring $\mathfrak{H}(X)$ of holomorphic functions on X (equipped with the topology of compact convergence), there exist $f_1, \cdots, f_n \in a$ such that the varieties of $(f_1, \cdots, f_n)$ and of a coincide. A counterexample shows that the proof of this theorem fails in the algebraic case. (ii) Let X be a holomorphically complete, n-dimensional complex manifold. Then, for the holomorphic vector bundle W of rank d over X, the $\mathfrak{H}(X)$-module $H^0(X, \mathcal{O}(W))$ is generated by $d + [n/2]$ elements. In particular, every purely $(n-1)$-dimensional analytic subset of a holomorphically complete, n-dimensional complex manifold can be written as the set of common zeros of $1 + [n/2]$ holomorphic functions.

H. Röhrl (La Jolla, Calif.)

Spallek, Karlheinz 4913

Tensorielle Beschränkungen analytischer Garben.

Math. Z. **84** (1964), 448–463.

This paper contains a generalization of the classical Hartogs-Osgood theorem to sections in analytically coherent sheaves. Let B be an open subset in $\mathbf{C}^n$, $\mathcal{O}$ the sheaf of germs of holomorphic functions on B, and $\mathcal{H}$ a coherent subsheaf of the coherent sheaf $\mathcal{G}$ over B, $j: \mathcal{H} \to \mathcal{G}$ being the injection. Furthermore, let $\mathcal{J}$ be a coherent sheaf of ideals on B. Then the image of $\mathcal{H}$ under the composite homomorphism

$$\mathcal{H} \xrightarrow{\cong} \mathcal{H} \otimes_{\mathcal{O}} \mathcal{O} \to \mathcal{H} \otimes_{\mathcal{O}} \mathcal{O}/\mathcal{J} \xrightarrow{j \otimes \mathrm{id}} \mathcal{G} \otimes_{\mathcal{O}} \mathcal{O}/\mathcal{J}$$

is called the tensorial restriction of $\mathcal{H}$ to $\mathcal{J}$ with respect to $\mathcal{G}$ and is denoted by $\mathcal{H}(\mathcal{G})|\mathcal{J}$. In a straightforward fashion one defines now the tensorial restriction

of a homomorphism $h: \mathscr{G} \to \mathscr{G}'$ satisfying $h(\mathscr{K}) \subset \mathscr{K}'$. A similar construction can be carried out for germs. Next, given the integers l and m and the family $\mathfrak{A} = \{A_z^l\}$ of germs of l-dimensional analytic planes in points $z \in B$, one defines $\mathscr{K}[\mathfrak{A}, m]$ to be the subsheaf of $\mathscr{G}$ consisting of all those germs g_z that are in $\mathscr{K}_z(\mathscr{G}_z)|\mathscr{I}^m(A_z^l)$ for all $A_z^l \in \mathfrak{A}$. For sufficiently large families $\mathfrak{A}$, the existence of an analytic set $A \subset B$ of codimension $\geq l+1$ can be established such that $\mathscr{K}[\mathfrak{A}, 1] \subset \mathscr{K}[A]$ holds, the latter being the coherent subsheaf of $\mathscr{G}$ consisting of all those germs presentable by local sections g satisfying $g|\, U - A \in \Gamma(U - A, \mathscr{K})$. If, in addition, for every $z \in B$ the primary decomposition of $\mathscr{K}_z$ in $\mathscr{G}_z$ has only primary components of dimension $\geq n-l$, then $\mathscr{K}[\mathfrak{A}, 1] = \mathscr{K}$. The same conclusion can be drawn from the hypothesis $\operatorname{codim}_z(\mathscr{G}_z/\mathscr{K}_z) \geq n-l$. Several more statements of this type are proved.

Abramowitz, Milton; Stegun, Irene A. (Editors) 4914

★**Handbook of mathematical functions with formulas, graphs, and mathematical tables.**

National Bureau of Standards Applied Mathematics Series, 55.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C., 1964. xiv + 1046 *pp*. $6.50.

This volume is the culmination of seven years of labor by 26 authors, mostly associates of the National Bureau of Standards, and the two editors, who also served as authors. In each of its 29 chapters are given definitions, formulas, short tables, graphs, polynomial approximations, and bibliographies of the pertinent functions.

The titles of the chapters are as follows. Mathematical Constants. Physical Constants and Conversion Factors. Elementary Analytical Methods. Elementary Transcendental Functions. Exponential Integral and Related Functions. Gamma Function and Related Functions. Error Function and Fresnel Integrals. Legendre Functions. Bessel Functions of Integer Order. Bessel Functions of Fractional Order. Integrals of Bessel Functions. Struve Functions and Related Functions. Confluent Hypergeometric Functions. Coulomb Wave Functions. Hypergeometric Functions. Jacobian Elliptic Functions and Theta Functions. Elliptic Integrals. Weierstrass Elliptic and Related Functions. Parabolic Cylinder Functions. Mathieu Functions. Spheroidal Wave Functions. Orthogonal Polynomials. Bernoulli and Euler Polynomials. Riemann Zeta Function. Combinatorial Analysis. Numerical Interpolation, Differentiation and Integration. Probability Functions. Miscellaneous Functions. Scales of Notation. Laplace Transforms.

Many of the tables are new. Each column of a table for which interpolation is feasible is supplied with two indicators: one gives the maximum error in case linear interpolation is used, the other indicates how many points of Lagrangian interpolation are needed to exploit the full accuracy of the local table. There are many illustrative examples. The difficult format problems have been solved successfully.

The widespread availability of automatic computers has not eliminated the need for mathematical tables, but rather has modified the kind of information required. The needs now are small basic tables for reconnaissance handwork and for possible inclusion in special subroutines, together with copious lists of formulas for the generation, transformation and approximation of functions.

This magnificent volume is destined to become the new standard reference for workers in the field of computational mathematics.

D. H. Lehmer (Berkeley, Calif.)

Curtis, A. R. 4915

★**Coulomb wave functions.**

Prepared under the direction of The Coulomb Wave Functions Panel of the Mathematical Tables Committee. Royal Society Mathematical Tables, Vol. 11.

Published for the Royal Society at the Cambridge University Press, New York, 1964. xxxv + 209 *pp*. $15.00.

These functions are solutions of the differential equation

$$y'' + (a + 2x^{-1} - L(L+1)x^{-2})y = 0,$$

where $x > 0$, a is real and L is zero or a positive integer (in the tables $L = 0, 1$ or 2) which arises by separating off the radial component in the Schrödinger equation for an electron in a Coulomb field. There is some difficulty in deciding on the standard solutions to be tabulated, having regard to the convenience of the user (e.g., with regard to interpolation in energy parameter a) and taking account of the necessity of having the solutions "numerically" as well as analytically independent. The actual solutions chosen are too complicated to be given here and are different in the ranges $a \geq 0$, $a < 0$. Suffice it to say that 6D tables of the solutions and their first x-derivatives are given (or readily obtainable) for all x and for $a = -2(.2)2$. [For large x, the independent variables x^{-1} or $x^{-1/2}$ are used.] The values are said to be good within .6 units in the last place.

To aid interpolation in the x-direction by Everett's formula with throw-back, second and fourth differences (modified when necessary) are given. Auxiliary functions for interpolation in the irregular solution near $x = 0$ are given.

There is an elaborate introduction which discusses the choice of solution, recurrence relations, asymptotic and other representations. Interpolation is illustrated by worked examples, and the preparation and checking of the table is described carefully. Much of the material was obtained by integrating the differential equation by the Runge-Kutta method, sometimes using a double precision program. The values of some of the functions for large arguments were computed automatically from a Chebyshev expansion (in terms of the reciprocal variable), the coefficients of which were obtained by desk calculations. Special tablemaking subroutines were employed, e.g., to produce the modified differences from the tabular values, and for editing purposes.

The tables were reproduced photographically from copy prepared by a card-controlled typewriter. A few imperfections are clarified in an inset.

There is a substantial bibliography. For some further references see the chapter by M. Abramowitz on Coulomb Wave Functions in #4914 reviewed above.

★**Tables of Jacobian elliptic functions whose arguments are rational fractions of the quarter period.**

National Physical Laboratory Mathematical Tables, Vol. 7. Department of Scientific and Industrial Research.

Her Majesty's Stationery Office, London, 1964. iii+81 *pp*. 15*s*.; $3.00.

This table gives values to 20D of $\mathrm{sn}(u, k)$, $\mathrm{cn}(u, k)$, $\mathrm{dn}(u, k)$, where $u = mK/n$ for $m = 1(1)(n-1)$, $n = 2(1)15$. The values of k are those which correspond to $q = 0(.005).35$ and lie in the range 0 to .99933. For each value of q, the corresponding values of k, k', $\theta = \sin^{-1} k$, K, K', K/K' are given to 20D.

The calculations were performed, at triple-precision, on the DEUCE, summing the Fourier series for the theta function for angular argument π/n. From these theta values the elliptic functions for argument K/n were formed and from these the addition formulae gave the values for argument mK/n. Various functional relations were satisfied to within a unit in the 25th decimal. It is stated that the tabular values are in error by less than half a unit in the 20th decimal.

An alternative computation based on the Gauss arithmetic-geometric mean is described; the use of this is indicated for the case when tabulations are required with k as the independent variable.

{(1) These tables were prepared to facilitate computations occurring in a method of filter design proposed by S. Darlington [J. Math. Phys. Mass. Inst. Tech. **18** (1939), 257–353; MR **1**, 275]. We note that a similar scheme was developed by W. Cauer [see, e.g., Math. Z. **38** (1933), 1–44; *Synthesis of linear communication networks*, Vols. 1, 2, second edition, McGraw-Hill, New York, 1958; MR **20** #4416], and that tables to assist in its use were prepared by W. Glowatzki [Abh. Bayer. Akad. Wiss. Math.-Natur. Kl. (N.F.) No. 67 (1955); MR **16**, 1153]. See also R.A.-R. Amer and H. R. Schwarz [Mitt. Inst. Angew. Math. Zürich No. 9 (1964); MR **29** #4639]. (2) These tables have an interesting application in the theory of alternating implicit direction methods. W. B. Jordan [see E. L. Wachspress, J. Soc. Indust. Appl. Math. **11** (1963), 994–1016; MR **29** #6623] obtained the optimal parameters for the solution of the "model" problem, and these are essentially among the values of the elliptic functions tabulated, the k of the elliptic functions being related to the estimates of the eigenvalues in the discrete version of the "model" problem.} *John Todd* (Pasadena, Calif.)

Karpov, K. A. 4917

★**Tables of the functions $F(z) = \int_0^z e^{x^2}\,dx$ in the complex domain.**

Translated by D. E. Brown. Mathematical Tables Series, Vol. 23. A Pergamon Press Book.

The Macmillan Co., New York, 1964. xxv+497 *pp*. (3 *inserts*) $20.00.

This is an English version of the Russian book [Izdat. Akad. Nauk SSSR, Moscow, 1958] noted in MR **24** #B1297, a companion to the author's earlier volume [*Tables of the function $w(z) = e^{-z^2}\int_0^z e^{x^2}\,dx$ in a complex region* (Russian), Izdat. Akad. Nauk SSSR, Moscow, 1954; MR **16**, 749]. Together, these volumes make readily accessible values, to 5D or to 5S, of the error function in the whole complex plane, with a polar argument; for a cartesian argument see the tables of V. N. Faddeeva and N. M. Terent'ev [*Tables of values of the function $e^{-z^2}(1 + 2i\pi^{-1/2}\int_0^z e^{t^2}\,dt)$ for a complex argument* (Russian), GITTL, Moscow, 1954; MR **16**, 960; English transl., M. D. Friedman, Newtonville, Mass., 1956; MR **18**, 155].

The actual contents of this table are: (1) the real and imaginary parts of $F(\rho e^{i\theta}) = u + iv$ for $0 \leq \rho \leq \rho_0 = \rho_0(\theta)$, $\frac{1}{4}\pi \leq \theta \leq \frac{1}{2}\pi$, where ρ_0 ranges from 5 to 3; the intervals in ρ, θ vary and are indicated on an insert. (2) The values of $F(\rho)$ for $\rho = 0(.001)10$. Second differences are given in the range [3, 10] and an insert table of $\frac{1}{4}t(1-t)$ and a nomogram to calculate the second difference correction in Bessel interpolation is provided.

In the introduction various integral representations, series expansions and differential equations for u and v are given, together with graphs and reliefs. In particular, asymptotic series appropriate for calculating u and v beyond the range of tabulation are given; auxiliary tables to facilitate such calculations are provided.

In the main table linear interpolation along radii is adequate but on the circles $\rho = \mathrm{const}$, higher-order Lagrangian interpolation is recommended. [A diagram indicates which order is required; generally 4-point is sufficient.] Worked examples illustrate interpolation.

The tables were computed using a piecewise approximation to the solution of simultaneous second-order differential equations for u and v by polynomials of degree 14 in ρ; the evaluation of the polynomials was carried out by tabulators [K. A. Karpov, Dokl. Akad. Nauk SSSR **62** (1948), 741–744; MR **10**, 405].

The printing is clear, but in the review copy pages 216–217 were blank. The translation of the introduction is adequate. *John Todd* (Pasadena, Calif.)

Tabelle der (Relativ)-Klassenzahlen der Kreiskörper, deren φ-Funktion des Wurzelexponenten (Grad) nicht grösser als 256 ist.

Abh. Deutsch. Akad. Wiss. Berlin Kl. Math. Phys. Tech. **1964**. *no.* 2, 64 *pp*.

Eastham, M. S. P. 4919

On polylogarithms.

Proc. Glasgow Math. Assoc. **6**, 169–171 (1964).

The nth-order polylogarithm, $\mathrm{Li}_n(z)$, is defined by $\mathrm{Li}_n(z) = \sum z^r r^{-n}$ $(n = 2, 3, \cdots)$. Extend the sequence by $z\,\mathrm{Li}_n'(z) = \mathrm{Li}_{n-1}(z)$. Then it is shown that no recurrence formula of the form $\sum_{j=0}^{m} A_j(z)\,\mathrm{Li}_{n-j}(z) = 0$ holds, where $A_j(z)$ are algebraic functions of z, $A_0(z)$ is not identically zero, and $m \geq 1$. Also, a generating function for $\mathrm{Ai}_n(z)$, $n = 2, \cdots$, is found and it is used to sum some series involving $\mathrm{Li}_n(z)$. *R. A. Askey* (Madison, Wis.)

Tricomi, Francesco 4920

Sul comportamento asintotico della funzione gamma incompleta $\Gamma(\alpha, x)$ al simultaneo divergere di α e x.

Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 333–339.

In an earlier paper [Math. Z. **53** (1950), 136–148; MR **12**, 553] the author investigated the asymptotic behaviour of $\Gamma(\alpha + 1, x)$ as $\alpha \to \infty$ while $y = (x - \alpha)/\sqrt{(2\alpha)}$ is bounded. He now gives a new method for carrying out the same investigation. The earlier method produced a series in

descending powers of α for a certain multiple of $\Gamma(\alpha+1, x)$. The new method yields a more complicated series, but it is an easy matter to extract the leading terms of the expansion in descending powers of α.

A. Erdélyi (Edinburgh)

Glasser, M. L. 4921

Note on the evaluation of some Fermi integrals.

J. Mathematical Phys. 5 (1964), 1150–1152.

The author evaluates integrals of the type

$$\int_0^\infty f(E)g(E, \gamma, \zeta)\, dE,$$

either explicitly or asymptotically (ζ, γ large), where $f(E)$ is an analytic function that possibly contains algebraic or logarithmic branch-point singularities and $g(E, \gamma, \zeta) = \frac{1}{4}\operatorname{sech}^2[\frac{1}{2}\gamma(E-\zeta)]$, where $\gamma = 1/kT$ and ζ is the Fermi energy parameter. Several examples of frequent occurrence in theoretical physics are discussed.

C. J. Bouwkamp (Eindhoven)

Bhowmick, K. N. 4922

Some recurrence relations for a generalized Struve transform.

Ganita 14 (1963), 89–97.

The author obtains various recurrence relations for the generalized Struve transform $F_{\mu,\nu}^{\lambda}[g]$ which is defined by means of

$$F_{\mu,\nu}^{\lambda}[g] = \int_0^\infty (xy)^\mu H_\nu^\lambda(xy) g(y)\, dy,$$

where

$$H_\nu^\lambda(x) = \sum_{r=0}^\infty \frac{(-1)^r(\frac{1}{2}x)^{\nu+2r+1}}{\Gamma(r+\frac{3}{2})\Gamma(\nu+\lambda r+\frac{3}{2})} \quad (\lambda > 0).$$

We cite as a sample the relation

$$\lambda x^{1-\nu}\frac{d}{dx}[x^\nu F_{\mu,\nu}^\lambda[g(x)]] =$$

$$\{(\mu+\nu+\eta+1)-2\nu-1\}F_{\mu,\nu-1}^\lambda[g(x)] + F_{\mu+1,\nu-1}^\lambda[g(x)].$$

W. A. Al-Salam (Lubbock, Tex.)

Braaksma, B. L. J. 4923

Asymptotic expansions and analytic continuations for a class of Barnes-integrals.

Compositio Math. 15, 239–341 (1964).

The H-function is defined by

$$H(z) = \frac{1}{2\pi i}\int_C \frac{\prod_1^n \Gamma(1-a_j+\alpha_j s)\prod_1^m \Gamma(b_j-\beta_j s)}{\prod_{m+1}^q \Gamma(1-b_j+\beta_j s)\prod_{n+1}^p \Gamma(a_j-\alpha_j s)} z^s\, ds,$$

where $0 \le n \le p$, $1 \le m \le q$, α_j, β_j are positive numbers and a_j, b_j may be complex. It is also assumed that the poles of the numerator are simple and that the contour C can be drawn so as to divide the complex s-plane into two parts so that the poles of $\Gamma(1-a_j+\alpha_j s)$, $j = 1, 2, \cdots, n$, all lie on the left of C and those of $\Gamma(b_j-\beta_j s)$ on the right.

The H-function contains a vast number of well-known analytic functions as special cases and also an important class of symmetrical Fourier kernels of a very general nature.

If $\mu = \sum_1^q \beta_j - \sum_1^p \alpha_j$ and $\beta = \prod_1^p \alpha_j^{\alpha_j}\prod_1^q \beta_j^{-\beta_j}$, then (Theorem 1) the author proves that the H-function exists for $\mu > 0$ and $z \ne 0$, or $\mu = 0$ and $0 < |z| < \beta^{-1}$. Theorem 2 gives conditions for the analytic continuation of $H(z)$ into the domain $|z| > \beta^{-1}$.

In Theorems 3 to 9, inclusive, the author discusses the asymptotic expansion of $H(z)$ as $|z| \to \infty$, when $\mu > 0$. Such asymptotic expansions are sometimes exponentially large, sometimes of algebraic order and sometimes exponentially small, mainly according to the value of $\arg z$. The discussion is complete, but it is not possible to give details in a brief review.

The H-function reduces to the G-function when $\alpha_j = 1$, $j = 1, 2, \cdots, p$, and $\beta_j = 1$, $j = 1, 2, \cdots, q$. In Theorems 10 to 17, inclusive, the author discusses the asymptotic behaviour of the G-functions as $|z| \to \infty$. In the case when $n = 0$ both the H- and the G-functions have exponentially small asymptotic expansions.

In the rest of the paper the author discusses the asymptotic expansions of hypergeometric series which are closely connected with the H-function. They are

$$\chi(z) = \sum_{\nu=0}^\infty \frac{\prod_1^n \Gamma(\alpha_j\nu+a_j)z^\nu}{\nu!\prod_1^q \Gamma(\beta_j\nu+b_j)\prod_{n+1}^p \Gamma(1-a_j-\alpha_j\nu)},$$

where, as before, α_j ($j = 1, 2, \cdots, p$) and β_j ($j = 1, 2, \cdots, q$) are positive numbers, while a_j and b_j can be complex. The following particular cases of $\chi(z)$ are also discussed in detail:

$${}_p\psi_q(z) = \sum_{\nu=0}^\infty \frac{\prod_1^p \Gamma(\alpha_j\nu+a_j)z^\nu}{\nu!\prod_1^q \Gamma(\beta_j\nu+b_j)},$$

$$\phi(z) = \sum_0^\infty \frac{z^\nu}{\nu!\Gamma(b-\sigma\nu)},$$

where $0 < \sigma < 1$ and b is real.

The author gives a comprehensive discussion of the asymptotic behaviour, as $|z| \to \infty$, of all these hypergeometric functions.

The author fails to give, at the end of the paper, an index of symbols with references to the place in the paper where they are defined. Such an index should be given for all papers of this size.

C. Fox (Montreal, Que.)

Verma, A. 4924

Integration of bilateral hypergeometric series with respect to their parameters.

J. London Math. Soc. 39 (1964), 673–684.

A bilateral series is a hypergeometric series which is infinite in both directions. In this paper, the author evaluates certain general contour integrals of Barnes's type, where the integrand involves one or two of these bilateral series. He also gives the corresponding results involving basic bilateral series.

L. J. Slater (Cambridge, England)

Verma, Arun 4925

Series involving products of two E-functions.

Proc. Glasgow Math. Assoc. 6, 172–176 (1964).

The author evalutes six bilateral series involving products of two E-functions. The series are too complicated to reproduce here. *W. A. Al-Salam* (Lubbock, Tex.)

Al-Salam, W. A.; Carlitz, L. 4926

Bateman's expansion for the product of two Bessel functions.

Ann. Mat. Pura Appl. (4) **65** (1964), 97–111.

It is shown that the general solution of the functional equation

$$\text{(F)}\quad g_\mu[(1-x)(1-y)z]g_\nu(xyz) = \sum_{n=0}^{\infty}\frac{(-1)^n n!A_n(x)A_n(y)z^n g_{\mu+\nu+2n+1}(z)}{(\mu+1)_n(\nu+1)_n(\mu+\nu+n+1)_n}$$

($A_n(x)$ a polynomial in x of degree n; $\mu, \nu > -1$) of the form

$$g_\nu(z) = \sum_{n=0}^{\infty}(-1)^n c_n{}^\nu z^n,$$

$c_1{}^\nu \neq 0$ and continuous in ν, occurs when

$$c_n{}^\nu = \frac{a^{2n}}{n!(\nu+1)_n},\quad a \text{ an arbitrary constant.}$$

Bateman showed that $\Gamma(\nu+1)z^{-\nu/2}J_\nu(2\sqrt{z})$ satisfies (F), where $J_\nu(z) = \sum_{n=0}^{\infty}(-1)^n(\frac{1}{2}z)^{\nu+2n}/n!\Gamma(\nu+n+1)$ is the Bessel function of order ν.

A generalization of (F) is also considered.

A. E. Danese (Buffalo, N.Y.)

Epstein, Leo F. 4927

Some infinite sums involving zeros of $J_0(x)$.

J. Res. Nat. Bur. Standards Sect. B **68B** (1964), 17–26.

Let β_n denote the nth positive zero of the Bessel function $J_0(x)$. Sums of the form

$$F_r(\phi) = \sum_{n=1}^{\infty}(1/\beta_n)^{2r}\exp(-\beta_n{}^2\phi)$$

and

$$G_r(\phi) = \sum_{n=1}^{\infty}\frac{\exp(-\beta_n{}^2\phi)}{\beta_n{}^{2r-1}J_1(\beta_n)},$$

where r is an integer and $\phi > 0$, occur in a study of diffusion processes under conditions of axial symmetry. For $r = 0(1)3$, the author derives approximations in powers of $\phi^{1/2}$ as $\phi \to 0$ in the case of F_r. Analogous expansions are obtained for G_r and a few more complicated functions involving error functions. These expansions are useful in the numerical evaluation of the several functions as ϕ tends to zero from above. *C. J. Bouwkamp* (Eindhoven)

Heading, J. 4928

Transition point values.

J. London Math. Soc. **39** (1964), 466–480.

The value of the parabolic cylinder function $D_{-1/2+ia^2/2}(z)$ at the transition point $z = 2^{1/2}e^{\pi i/4}a$ is determined asymptotically for large complex values of a by the method of steepest descents, and also by application of the asymptotic theory of ordinary differential equations. The results obtained agree with those previously given by the reviewer [J. Res. Nat. Bur. Standards Sect. B **63B** (1959), 131–169; MR **22** #781].

F. W. J. Olver (Washington, D.C.)

Jorna, S. 4929

Derivation of Green-type, transitional, and uniform asymptotic expansions from differential equations. I. General theory, and application to modified Bessel functions of large order.

Proc. Roy. Soc. Ser. A **281** (1964), 99–110.

Consider the differential equation

$$d^2y/dx^2 = \chi(a^2, x)y,$$

in which a is a large parameter and $\{\chi(a^2, x)\}^{-1/4}$ is a bounded, slowly-varying function of x in the region of integration. It is well known that uniform asymptotic solutions exist of the form

$$\text{(1)}\quad y = \chi^{-1/4}\exp\left\{\pm\int^x \chi^{1/2}\,dx\right\}\sum_{s=0}^{\infty}(-1)^s v_s(a^2, x),$$

where $v_0(a^2, x) = 1$, and the higher terms $v_s(a^2, x)$ are given by recurrence relations. Furthermore, in one case in which these conditions are violated and the region of integration contains a simple zero of $\chi(a^2, x)$—a "transition point" of the differential equation—uniform asymptotic expansions for the solutions can be found in terms of Airy functions.

The novelty of the present paper is the way in which these two kinds of expansions, particularly the second, are derived. The $v_s(a^2, x)$ in (1) are obtained by solving an integro-differential equation by successive approximation. The same integro-differential equation is used in the case of a transition point; the expansions of the solutions in Airy functions are obtained with the aid of the Mellin transform and the Nörlund summation operator.

The methods are illustrated by application to Bessel functions of large order, and the results compared with those of the reviewer [Philos. Trans. Roy. Soc. London Ser. A **247** (1954), 328–368; MR **16**, 696]. Much of the analysis is purely formal, with no attempt at determining the regions of validity in the complex plane.

F. W. J. Olver (Washington, D.C.)

Jorna, S. 4930

Derivation of Green-type, transitional, and uniform asymptotic expansions from differential equations. II. Whittaker functions $W_{k,m}$ for large k, and for large $|k^2 - m^2|$.

Proc. Roy. Soc. Ser. A **281** (1964), 111–129.

The methods described in the preceding paper [#4929] are applied to the Whittaker form of the confluent hypergeometric equation

$$\frac{d^2W}{dz^2} = \left(\frac{1}{4} - \frac{k}{z} + \frac{m^2 - \frac{1}{4}}{z^2}\right)W,$$

in the cases (i) k large and m fixed, (ii) $|k^2 - m^2|$ large. Asymptotic expansions in terms of elementary functions are obtained, valid in regions excluding the transition points $z = 4k$ (case (i)), $z = 2k \pm 2(k^2 - m^2)^{1/2}$ (case (ii)). Uniform expansions in terms of Airy functions which are valid in regions containing the transition points are also obtained. The results are compared with those of earlier writers. The special cases of Weber parabolic cylinder functions, and especially Poiseuille functions, are examined in detail. *F. W. J. Olver* (Washington, D.C.)

Lindsey, William C. 4931

Infinite integrals containing Bessel function products.

J. Soc. Indust. Appl. Math. **12** (1964), 456–464.

The author evaluates the integral

$$\int_0^\infty x^m \exp(-kx^2) I_{m-1}(bx) I_n(\lambda x^2)\, dx,$$

where $k>\lambda$, n and m are integers and $I_l(z)$ is the modified Bessel function of imaginary argument and order l, and gives the result in a very complicated form. The result is suitable for making numerical computations.

Brij Mohan (Varanasi)

Srivastava, K. N. 4932

On analogies between some series containing Bessel functions and certain integrals.

Ricerca (Napoli) (2) **14** (1963), *maggio-agosto*, 22–26.

The author shows that

$$2a^{-2}\sum_{s=1}^{\infty}\frac{\alpha_s{}^{\nu}J_\mu[\sqrt{(\alpha_s{}^2+\beta^2)}]}{(\alpha_s{}^2+\beta^2)^{\mu/2}J_{\nu+1}(\alpha_s a)}J_\nu(\alpha_s\gamma) =$$

$$\int_0^\infty x^{\nu+1}(x^2+\beta^2)^{-\mu/2}J_\mu[\sqrt{(x^2+\beta^2)}]J_\nu(x\gamma)\, dx,$$

where $\beta>0$, $\mu>\nu>-1$ {the paper has erroneously >1}, $a>1$, $0<\gamma<1$ or $1<\gamma<a$, and the α_s are the positive roots of $J_\nu(\alpha a)=0$. The proof is given by representing

$$f(\gamma) = \beta^{\nu-\mu+1}\gamma^\nu(1-\gamma^2)^{(\mu-\nu-1)/2}J_{\mu-\nu-1}[\beta\sqrt{(1-\gamma^2)}] \qquad \text{if } 0<\gamma<1,$$

$$= 0 \qquad \text{if } \gamma>1$$

{the paper has erroneously $J_{\mu-\nu-1}[\beta(1-\gamma^2)]$} on the one hand as a Fourier-Bessel series for $0<\gamma<a$, and on the other hand as a Hankel transform.

There are five other similar formulae. {If $F(\gamma)$ vanishes for $\gamma\geq a$, then there is an obvious relation between the Fourier-Bessel coefficients for the interval $(0,a)$, and the Hankel transform, of F. The author's results are trivial examples of that relation.}

A. Erdélyi (Edinburgh)

Srivastava, K. N. 4933

On some integrals involving Gegenbauer polynomial and Chebychev polynomial of first kind.

Ricerca (Napoli) (2) **14** (1963), *gennaio-aprile*, 10–16.

The following result is obtained:

$$\int_0^1 \frac{C_n{}^\lambda[(xz+1)^{1/2}]C_{n-1}^{-\lambda}\left[\left(\frac{xz+1}{z+1}\right)^{1/2}\right]}{x^{1/2-\lambda}(1-x)^{1/2+\lambda}(xz+1)^{1/2}}\, dx =$$

$$\frac{2\pi}{\cos\pi\lambda}(z+1)^{(n-2\lambda-1)/2}{}_2F_1[n,-\lambda;1;-z],$$

$-\frac{1}{2}<\lambda<\frac{1}{2}$, $C_n{}^\lambda$ the Gegenbauer or ultraspherical polynomial of degree n and order λ, by using a certain explicit expression for $C_n{}^\lambda$. The case $\lambda=0$, $C_n{}^0=T_n$, the Chebyshev polynomial of the first kind, is of interest.

A. E. Danese (Buffalo, N.Y.)

Mukherjee, S. N. 4934

On some integrals involving Gegenbauer polynomials and associated Legendre polynomials.

J. Sci. Res. Banaras Hindu Univ. **14** (1963/64), no. 1, 145–150.

Integrals such as

$$\int_0^\infty x^\sigma(1-x^2)^{-\mu/2}P_\nu{}^\mu(x)J_\lambda(2\alpha tx)J_\delta(2\beta tx)\, dx,$$

$$\int_0^\infty x^\sigma(1-x^2)^{\delta-1/2}C_\nu{}^\delta(x)J_\lambda(2\alpha tx)J_\delta(2\beta tx)\, dx,$$

$$\int_0^1 x^\sigma(1-x^2)^{-\mu/2}P_\nu{}^\mu(x)\,{}_pF_q\left[\begin{matrix}\alpha_1,\ldots,\alpha_p\\ \beta_1,\ldots,\beta_p\end{matrix};\pm x^2t^2\right]J_\mu(2xt)\, dx,$$

where $P_\nu{}^\mu$ are the associated Legendre polynomials and $C_\nu{}^\delta$ are the Gegenbauer polynomials, are evaluated by expanding the Bessel functions in series and integrating term by term. The results are too complicated to be reproduced here.

A. E. Danese (Buffalo, N.Y.)

Scott, E. J. 4935

A formula for the derivatives of Tchebychef polynomials of the second kind.

Amer. Math. Monthly **71** (1964), 524–525.

By using properties of Gegenbauer polynomials, the author derives a formula for the derivatives of Tchebychef polynomials U_n analogous to one for Legendre polynomials conjectured by D. Đoković [Univ. Beograd. Publ. Elektrotehn. Fak. Ser. Mat. Fiz. No. 65–69 (1961), 5–8; MR **25** #2245] and proved by the reviewer [Amer. Math. Monthly **70** (1963), 643–644; MR **28** #263]. The reviewer has recently learned that the following formula, which includes both the Legendre and Tchebychef formulas as special cases, was proved by L. Gegenbauer [Denkschr. Akad. Wiss. Math.-Natur. Cl. Wien. **48** (1884), 293–316]:

$$[C^\nu_{n+\alpha p}(x)]^{(\alpha p)} = \frac{2^{\alpha p}\Gamma(\nu+\alpha p)}{\Gamma(\nu)}\sum C^\nu_{n_1}C^\nu_{n_2}\cdots C^\nu_{n_{\alpha q+1}},$$

where the C's are the Gegenbauer polynomials, $\nu=p/q$, α is an integer, and the sum is over all subscripts whose sum is n.

Mary L. Boas (Chicago, Ill.)

Haradze, A. K. 4936

On the representation of ultraspherical polynomials in the form of a differential operator containing the generating function of these polynomials. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 59–61.

The following representations of ultraspherical polynomials are established

$$y^{n/2\lambda}P_n{}^{(\lambda)}(x) = P_n{}^{(\lambda)}(z)+\binom{\omega}{1}ty^{1/2\lambda}P^{(\lambda)}_{n-1}(z)+\cdots$$

$$+\binom{\omega}{n}t^ny^{n/2\lambda}P_0{}^{(\lambda)}(z),$$

$$y^{(n+\lambda)/\lambda}P_n{}^{(\lambda)}(x) = D_n{}^{(\lambda)}[y] \equiv$$

$$\frac{y^{(n)}}{n!}+\binom{\omega}{1}ty^{1/\lambda}\frac{y^{(n-1)}}{(n-1)!}+\cdots+\binom{\omega}{n}t^ny^{n/\lambda+1},$$

where $z=y^{1/2\lambda}(x-t)$, $\omega=2\lambda+n-1$, $y=(1-2xt+t^2)^{-\lambda}$ is the generating function of these polynomials. It is obvious that the function $(1-2x_it+t^2)^{-\lambda}$ is the solution of the equation $D_n{}^{(\lambda)}[y]=0$, where x_i are the roots of the polynomials $P_n{}^{(\lambda)}(x)$.

B. S. Popov (Skopje)

Haradze, A. K. 4937

On sequences of polynomials of Appel type satisfying a recurrence relation. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 963–967.

Applying the technique of Carlitz's previous paper [Portugal. Math. **20** (1961), 43–46; MR **24** #A266], the author proves the following result. Let $\{f_n(x)\}$ be a sequence of the class of Appel polynomials satisfying

$$(*)\quad f_{n+1}(x)-2(x+b_n)f_n(x)+(x+b_n)^2f_{n-1}(x)+c_nf_{n-2}(x)=0,\qquad c_n>0,\ n\geq 2,$$

where b_n, c_n are independent of x. Then the solution of (*) is

$$f_n(x)=\alpha^n\left[H_{3;n}\left(\frac{x+\beta}{\alpha}\right)+Ch_{3;n-1}\left(\frac{x+\beta}{\alpha}\right)\right],$$

where α,β are constants and C an arbitrary constant. $H_{k;n}$ and $h_{k;n}$ are generalised Hermite polynomials [Chatterjee, Bull. Calcutta Math. Soc. **47** (1955), 27–41; MR **17**, 967; the author, ibid. **52** (1960), 25–34; MR **24** #A264]. *B. S. Popov* (Skopje)

Dou, Alberto 4939

Linear ordinary differential systems with constant coefficients. (Spanish. English summary)

Collect. Math. **14** (1962), 261–268.

The author defines a complex-valued scalar function $u(t)\in C^\infty$, on a real interval, to have finite differential dimension if the vector space generated by u and its derivatives has finite dimension. He shows that such a u is a linear combination of products of polynomials and exponentials, and obtains solutions in finite form of the system $x'=Ax+f(t)$, where A is an $n\times n$ constant matrix and f is a vector with entries having finite differential dimension. *W. A bound for a function with monotonely distributed zeros of successive derivatives. (Russian)

Mat. Sb. (*N.S.*) **64** (**106**) (1964), 396–409.

The main result [announced without proof in Dokl. Akad. Nauk SSSR **138** (1961), 37–38; MR **23** #A3310] of the paper is the following. If a real-valued function $x(t)$ of class C^n on (a,b) satisfies the conditions $x(a_1)=x'(a_2)=\cdots=x^{(n-1)}(a_n)=0$ $(a\leq a_1\leq a_2\leq\cdots\leq a_n\leq b)$ and $|x^{(n)}(t)|\leq\mu$ $(a\leq t\leq b)$, then

$$|x(t)|\leq\mu\frac{(b-a)^n}{n\left[\frac{n-1}{2}\right]!\left[\frac{n}{2}\right]!}\qquad(a\leq t\leq b),$$

and this inequality is the best possible. The proof uses the known theorem of M. G. Kreĭn and D. Milman on extreme points of regular convex sets [Studia Math. **9** (1940), 133–138; MR **3**, 90].

The author compares his result with an inequality obtained by S. N. Bernšteĭn [Izv. Akad. Nauk SSSR Ser. Mat. **14** (1950), 381–404; MR **12**, 322] without the hypothesis that the sequence $a_1,\cdots,a_n$ is non-decreasing.

In the second part of the paper the author proves that if

$$\sum_{k=1}^{n}L_k\frac{(b-a)^k}{2^kk\left[\frac{k-1}{2}\right]!\left[\frac{k}{2}\right]!}\leq 1,$$

then every non-trivial solution of the linear differential equation $x^{(n)}+p_1(t)x^{(n-1)}+\cdots+p_n(t)x=0$ $(a\leq t\leq b)$, where $p_i(t)$ is continuous on $[a,b]$ and $|p_i(t)|\leq L_i$ $(i=1,\cdots,n)$, has at most $n-1$ zeros on $[a,b]$. Thus he obtains a sharpening of an analogous estimate of Ch. de La Vallée Poussin [J. Math. Pures Appl. (9) 8 (1929), 125–144]. *Z. Opial* (Kraków)

Bačelis, R. D.; Melamed, V. G. 4942

Solution of a limiting boundary-value problem to which the generalized Stefan problem can be reduced. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 738–745.

The following free boundary diffusion problem is shown to have a solution of the form $u=\Phi(x/\sqrt{t})$, $\xi=\alpha\sqrt{t}$:

$$c(u)\frac{\partial u}{\partial t}=\frac{\partial}{\partial x}\left[\lambda(u)\frac{\partial u}{\partial x}\right],$$

with boundary conditions $u(0,t)=A\neq 0$, $u(x,0)=u(\infty,t)=B$, $AB\leq 0$, and $u=0$ at the free boundary $x=\xi(t)$. In addition, at $x=\xi$ there is a discontinuity in the flux λu_x proportional to the slope of the boundary curve. It follows that the function $\Phi(y)$, $y=x/\sqrt{t}$, satisfies a nonlinear ordinary differential equation if $y\neq\alpha$ with boundary conditions $\Phi(0)=A$, $\Phi(\infty)=B$. At $y=\alpha$, Φ' has a jump discontinuity proportional to α.

The authors prove that there is a unique choice of $\Phi'(0)$ (and therefore of α) such that the conditions of the problem are satisfied. They also give a method for constructing approximate solutions. *W. T. Kyner* (Los Angeles, Calif.)

Mil'man, V. D. 4943

A transformation operator for Sturm-Liouville differential equations in the non-selfadjoint case. (Russian)

Mat. Sb. (*N.S.*) **59** (**101**) (1962), *suppl.*, 145–164.

Consider the differential equations $u_j'' - g_j(x)u_j + \lambda^2 u_j = 0$ $(x \geq 0)$ with the initial-value problems $u_j'(0) = h_j$, $u_j(0) = 1$ $(j = 1, 2)$. Denote the solution of the problem by $v_j(x, \lambda)$ $(j = 1, 2)$. Let V be a linear operator in a function space which maps the function $v_1(\cdot, \lambda)$ into the function $v_2(\cdot, \lambda)$ for all complex λ. It is proved in the paper that under certain regularity conditions on the functions g_j, the operator admits an integral representation, and properties of the operator in certain function spaces are studied.

W. Bogdanowicz (Washington, D.C.)

Lees, Milton 4944

A boundary value problem for nonlinear ordinary differential equations.

J. Math. Mech. **10** (1961), 423–430.

From the author's introduction: "The purpose of this paper is to prove the following theorem. Let $f(x, z, p)$ be a continuous function defined in the region $0 \leq x \leq 1$, $-\infty < z, p < +\infty$. Assume that

$$(1.1) \qquad f(x, z_1, p) \geq f(x, z_2, p) \quad \text{for } z_1 \geq z_2$$

and

$$(1.2) \qquad |f(x, z, p_1) - f(x, z, p_2)| \leq K|p_1 - p_2|.$$

Then there exists a unique twice continuously differentiable function $z(x)$, defined for $0 \leq x \leq 1$, such that

$$(1.3) \qquad z(0) - z_0 = z(1) - z_1 = 0$$

and

$$(1.4) \qquad z''(x) = f(x, z(x), z'(x)) \qquad \left(' = \frac{d}{dx}\right)."$$

Bihari, I. 4945

The asymptotic behaviour of a system of nonlinear differential equations. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. 8 (1963), 475–488 (1964).

The author discusses the behavior as $t \to +\infty$ of the solutions of nonlinear systems of the form (1) $dx/dt = Ax + f(t, x)$, $x = (x_1, \cdots, x_n)$, $f = (f_1, \cdots, f_n)$, A an $n \times n$ constant matrix. As usual, the discussion is based on the comparison of the solutions of (1) with the solutions of the linear system $dy/dt = Ay$. Here $f(t, x)$ is defined for all $t \geq 0$, $x \in E_n$, and satisfies the relation

$$|f(t, x) - f(t, y)| \leq g(t)\omega(|x - y|)$$

for all $t \geq 0$, $x, y \in E_n$, where $g(t)$ is a given measurable bounded non-negative function with $\int_0^\infty g(t)dt < +\infty$, and $\omega(u)$, $u \geq 0$, is a continuous positive nondecreasing function of u with $\omega(0) = 0$, $\int_0^1 \omega^{-1}(u)du = \infty$, $\int_1^\infty \omega^{-1}(u)du = \infty$. If, in addition, every solution of (1) is bounded for $t \geq 0$, and $\omega^{-1}(u)$ satisfies a convenient condition of growth, then for every solution $x(t)$ of (1) there is a solution $y(t)$ of (2) such that $x(t) - y(t) \to 0$ as $t \to +\infty$. This theorem extends a previous one of N. Levinson and H. Weyl [N. Levinson, Amer. J. Math. **68** (1946), 1–6; MR **7**, 381; H. Weyl, ibid. **68** (1946), 7–12; MR **7**, 382]. Also it includes a previous remark of A. Wintner [ibid. **68** (1946), 13–19; MR **7**, 297]. *L. Cesari* (Ann Arbor, Mich.)

Kolodner, I. I.; Lehner, J.; Wing, G. M. 4946

On first order ordinary differential equations arising in diffusion problems.

J. Soc. Indust. Appl. Math. **12** (1964), 249–269.

In the scalar differential equation (*) $\dot{x} = g(t, x)$ let g satisfy the following set of hypotheses (H): $g(t, x)$ is a real-valued, continuously differentiable function for $t > 0$ and $x \geq 0$; $g_t < 0$ and $g_x < 0$; $g(t, 0) > 0$; $\lim_{t\to\infty} g(t, x) > -\infty$ always exists and $|g(t, 0)|$ is integrable in a neighborhood of $t = 0$. The authors prove theorems concerning existence, uniqueness and continuability of solutions of (*), as well as several results concerning the existence of extrema, inflection points, and asymptotic behavior of these solutions. Corresponding results, under a set of hypotheses weaker than (H), are stated without proof. The authors also study, under hypotheses similar to (H), an equation $\dot{y} = g(t, y, \beta)$, and obtain results concerning the influence of the parameter β upon the location of the extrema of the solutions. *T. On the absence of periodic solutions taking the value $x = 0$ in a class of differential equations of the form $\ddot{x} + x = F(x, \dot{x})$. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, no. 3 (40), 120–122.

The theorem proved for the absence of solutions of the type mentioned in the title is for

$$F(x, y) = F_1(x) + F_2(x) + F_3(x, y),$$

$$F_1(x) = \sum_{k=1}^{\infty} a_{2k}x^{2k}, \qquad a_{2k} \geq 0,$$

$$F_2(x) = \sum_{k=1}^{\infty} a_{2k+1}x^{2k+1},$$

$$F_3(x, y) = \sum_{m,n=0}^{\infty} a_{2m+1,2n+1}x^{2m+1}y^{2n+1},$$

and all $a_{2m+1,2n+1}$ have the same sign, F_1, F_3 not identically zero. *J. K. Hale* (Providence, R.I.)

Walter, Wolfgang 4948

Bemerkungen zu verschiedenen Eindeutigkeitskriterien für gewöhnliche Differentialgleichungen.

Math. Z. **84** (1964), 222–227.

It is shown in the paper that the uniqueness criterion for solutions of ordinary differential equations given by Krasnosel'skiĭ and Kreĭn [Uspehi Mat. Nauk (N.S.) **11** (1956), no. 1 (67), 209–213; MR **18**, 38], as well as that obtained by Brauer [Canad. J. Math. **11** (1959), 527–533; MR **21** #7319], can be reduced to Kamke's criterion [Kamke, *Differentialgleichungen reeller Funktionen*, Akademische Verlag, Leipzig, 1930].

Also, a result due to the reviewer [Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **8** (1960), 661–666; MR **24** #A2074] is reproduced and reproved in the paper.

C. Olech (Kraków)

Miller, Richard K. 4949

On almost periodic differential equations.

Bull. Amer. Math. Soc. **70** (1964), 792–795.

Consider the system (E) $x' = P(t, x)$ with P continuous on

$R^1 \times D$, D a domain in R^n, uniformly continuous on $R^1 \times D^*$ if D^* is a compact subset of D, and almost periodic in t for each fixed x. A subset A of D is called quasi-invariant with respect to (E) if for every $z \in A$ there is a $P^* \in \overline{H(P)}$, the closed hull of P, and a solution $y(t)$ of $y' = P^*(t, y)$ with $y(0) = z$ such that $y(t)$ is in a compact subset of A for all real t. It is shown that for a rather wide class of perturbed systems of (E), the positive limit set of a solution is quasi-invariant if it is compact. As corollaries of this result, the author generalizes several known stability theorems, e.g., those of Amerio [Ann. Mat. Pura Appl. (4) **39** (1955), 97–119; MR **18**, 128], LaSalle [Proc. Sympos. Appl. Math., Vol. XIII, pp. 299–307; Amer. Math. Soc., Providence, R.I., 1962; MR **25** #303], and Yoshizawa [Contributions to Differential Equations **1** (1963), 371–387; MR **26** #6487].

On the foundations of the method of harmonic balance. (Russian. English summary)

Analytic methods in the theory of non-linear vibrations (*Proc. Internat. Sympos. Non-linear Vibrations, Vol. I*, 1961), *pp.* 181–188. *Izdat. Akad. Nauk Ukrain. SSR, Kiev*, 1963.

Author's summary: "Sufficient conditions are given for the existence of a stable periodic solution of the differential equation $y = f(y, \dot y)$ in some estimated neighbourhood of an approximate solution $y = a \sin \omega t$, as defined by the method of harmonic balance, in the following cases: (1) the function $f(y, \dot y)$ is twice continuously differentiable; (2) the function $f(y, \dot y)$ is continuously differentiable; (3) the function $f(y, \dot y)$ is continuous. These conditions present some restrictions on $f(y, \dot y)$ and are not related to its piecewise linear approximation. For example, if the function $f(y, \dot y)$ is twice continuously differentiable, they will mean essentially that the Fourier coefficients of $f(a \sin u,\ a\omega \cos u)$, $f_y'(a \sin u,\ a\omega \cos u)$ and $f_{\dot y}'(a \sin u,\ a\omega \cos u)$ must be sufficiently small. A differential equation describing processes in an automatic control system of the second order is considered when, for example, the dry friction in a sensitive link is taken account of. By means of the results obtained for continuous functions $f(y, \dot y)$ one finds for this equation a neighbourhood of the approximate solution defined by the method of harmonic balance in which the exact periodic solution is contained."

Jakubovič, V. A. 4952

Absolute stability of non-linear control systems in critical cases. III. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 601–612.

In two recent papers [Avtomat. i Telemeh. **24** (1963), 293–303; MR **28** #311a; ibid. **24** (1963), 717–731; MR **28** #311b] the author made an extensive study of nonlinear control systems of the standard form

$$\text{(1)} \qquad \dot x = Ax + a\varphi(\sigma), \qquad \dot\sigma = b'x - \rho\varphi(\sigma),$$

under the assumption that φ is continuous, $\varphi(0) = 0$, $\sigma\varphi(\sigma) > 0$. In the present paper, many of the results are extended to the direct control case ($\rho = 0$) with φ possessing some finite jumps. The general additional restriction $0 < \sigma\varphi(\sigma) < \mu_0\sigma^2$, $\sigma \neq 0$, $\mu_0 \in (0, \infty)$, is made. The required new properties of dynamical systems are explicitly proved.

The notations are as follows: x, a, b are real n-vectors, φ and σ are scalars, A is a constant real $n \times n$ matrix. [The paper has a very extensive bibliography with 19 titles.]

S. Lefschetz (Princeton, N.J.)

Jakubovič, V. A. 4953

The method of matrix inequalities in the theory of stability of non-linear control systems. I. Absolute stability of forced vibrations. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 1017–1029.

In this paper the author discusses a control system with a forced disturbance $f(t)$:

$$\text{(1)} \qquad \dot x = Ax + a\varphi(\sigma) + f(t),$$

where the notations are those of the preceding paper [#4952], and in addition, $f(t)$ is a bounded n-vector. Several theorems on the nature of the solutions $x(t)$ of (1) are given. We mention just the following comparatively simple theorem. Let λ_h be the characteristic roots of A with $\operatorname{Re} \lambda_h < -\alpha < 0$. If σ_1, σ_2 are any two places where $\varphi(\sigma)$ is continuous ($\sigma_1 < \sigma_2$), assume that

$$0 < (\varphi(\sigma_1) - \varphi(\sigma_2))/(\sigma_1 - \sigma_2) \leq \mu_0 \leqq +\infty.$$

Suppose, also, that for all $\omega \geqq 0$, we have

$$\mu_0^{-1} + \operatorname{Re} \chi(-\alpha + i\omega) > 0, \quad \text{where } \chi(\lambda) = b'(A - \lambda I)^{-1}a,$$

and if $\mu_0 = \infty$, let $\lim_{\omega \to \infty} \omega^2 \operatorname{Re} \chi(-\alpha + i\omega) > 0$. Then the system (1) has a unique bounded solution $x_0(t)$ on $(-\infty, +\infty)$. It is exponentially stable in the large with exponent $-\alpha$. More precisely, there exist $\beta, \varepsilon > 0$ such that for $t > t_0$ any solution $x(t)$ satisfies

$$|x(t) - x_0(t)| \leq \beta \exp(-(\alpha + \varepsilon)(t - t_0))|x(t_0) - x_0(t_0)|.$$

The numbers ε, β are independent of $\varphi(\sigma)$. If $f(t)$ is periodic or almost periodic, so is $x_0(t)$. The paper concludes with 33 references. *S. Lefschetz* (Princeton, N.J.)

Lin, C. C. 4956

Some examples of asymptotic problems in mathematical physics.

Asymptotic Solutions of Differential Equations and Their Applications (*Proc. Sympos., Math. Res. Center, U.S. Army, Univ. Wisconsin, Madison, Wis.*, 1964), *pp.* 129–143. *Wiley, New York*, 1964.

A brief historical review of asymptotic approximations to the solutions of ordinary differential equations is given. Two recent examples from the author's own work in hydrodynamics and stellar dynamics, one, a fourth-order ordinary differential equation, and the other, a system of three first-order and one second-order partial differential equations, are perfunctorily described.

I. Kay (Ann Arbor, Mich.)

Ezeilo, J. O. C. 4957

An extension of a property of the phase space trajectories of a third order differential equation.

Ann. Mat. Pura Appl. (4) **63** (1963), 387–397.

For the third-order differential equation (1) $x''' + ax'' + bx' + h(x) = p(t, x, x', x'')$, equivalent to the system (2) $x' = y$, $y' = z$, $z' = -az - by - h(x) + p(t, x, y, z)$, the following theorem is proved: Suppose that (i) a, $b > 0$, $h(x)/x > 0$ for $|x| \geq 1$, (ii) $|h(x)| \to \infty$ as $|x| \to \infty$, (iii) $h'(x)$ is continuous for all x and $h'(x) \leq \gamma < ab$ for $|x| \geq 1$, (iv) there exists a constant $\Gamma > 0$, $ab > \Gamma \geq \gamma$, such that

$$\max(0, (\Phi'(x))^2 - 4\Gamma\Phi(x)) = O(|x|^\varepsilon) \quad \text{for } |x| \to \infty$$

($\Phi(x) = xh(x)$ and $0 \leq \varepsilon < 2$), (v) the function

$$\theta(R) = \max_{t \geq 0,\ |x|,|y|,|z| \leq R} |p(t, x, y, z)|$$

satisfies the condition $\theta(R) = o(h(\pm R))$ as $R \to \infty$. Then in the space (x, y, z) there exists a bounded closed surface Σ, starlike with respect to the origin, such that all trajectories of (2) cross Σ only inwards and any trajectory of (2) ultimately enters Σ.

This improves an earlier result of the same author [J. London Math. Soc. **37** (1962), 33–41; MR **25** #283] concerning the equation (1) in which the second member does not depend on x, x', x'' and $h(x)$ is assumed to satisfy considerably more restrictive conditions.

Z. Opial (Kraków)

Greguš, Michal 4958

Über die asymptotischen Eigenschaften der Lösungen der linearen Differentialgleichung dritter Ordnung.

Ann. Mat. Pura Appl. (4) **63** (1963), 1–10.

The equation considered is $y''' + 2A(x)y' + [A'(x) + b(x)]y = 0$, with $A'(x)$ and $b(x) \geq 0$ continuous in $(-\infty, \infty)$, and with $b(x)$ not identically zero in any interval. The principal results established are the following. (1) If $A(x) \leq 0$ for $x \in (-\infty, \infty)$, there exists at least one solution $y(x)$ which does not vanish in $(-\infty, \infty)$, and which is such that y and y' are monotone, $\operatorname{sgn} y(x) = \operatorname{sgn} y''(x) \neq \operatorname{sgn} y'(x)$, and $y'(x) \to 0$ as $x \to \infty$. (2) If $A(x) \leq 0$, $A'(x) + b(x) \geq 0$ for $x \in (-\infty, \infty)$, the solution $y(x)$ described in (1) has the further properties: $y''(x)$ is monotone, and $y''(x) \to 0$ as $x \to \infty$. (3) Under the hypotheses of (2), if the equation has one oscillatory solution, all solutions are oscillatory, with the exception of one solution $y(x)$, and its constant multiples, which have the following properties: $y(x) \neq 0$ for $x \in (-\infty, \infty)$, $\operatorname{sgn} y(x) = \operatorname{sgn} y''(x) \neq \operatorname{sgn} y'(x)$, y, y', and y'' are monotone, and $y'(x) \to 0$, $y''(x) \to 0$ as $x \to \infty$. (4) Under the hypotheses of (2), let the integral $\int_{x_0}^\infty t^2(A' + b)dt$ or the integral $\int_{x_0}^\infty b\,dt$ diverge. Then there exists a solution $y(x)$ which does not vanish for $x \in (-\infty, \infty)$, and which has the following properties: y, y', and y'' are monotone, $\operatorname{sgn} y = \operatorname{sgn} y'' \neq \operatorname{sgn} y'$, and $y \to 0$, $y' \to 0$, $y'' \to 0$ as $x \to \infty$.

L. A. MacColl (New York)

Červeň, J. 4959

A sufficient condition for non-oscillation of solutions of a linear third-order differential equation. (Slovak. Russian and German summaries)

Acta Fac. Natur. Univ. Comenian. **9**, 63–70 (1964).

Author's summary: "In der Arbeit wird die lineare Differentialgleichung dritter Ordnung (A), deren Koeffizienten stetige Funktionen sind, untersucht. Die Arbeit kann man in drei Teile teilen. Im ersten Teil werden nichtoszillatorische Eigenschaften der Bündel von Lösungen bei einigen Spezialbedingungen untersucht. Im zweiten Teil wird gezeigt, daß eine gewisse Bedingung eine hinreichende Bedingung für einen nichtoszillatorischen Charakter der Lösungen der Differentialgleichung (A) ist. Im dritten Teil sind Vergleichungssätze der Lösungen von zwei linearen Differentialgleichungen dritter Ordnung angeführt."

Sibuya, Yasutaka 4960

On the problem of turning points for systems of linear ordinary differential equations of higher orders.

Asymptotic Solutions of Differential Equations and Their Applications (*Proc. Sympos., Math. Res. Center, U.S. Army, Univ. Wisconsin, Madison, Wis.*, 1964), *pp.* 145–162. *Wiley, New York*, 1964.

In the differential equation

$$(1) \qquad \varepsilon^2\{y'' + R_1(z, \varepsilon)y' + R_2(z, \varepsilon)y\} = zDy$$

let y be a two-dimensional vector function of the complex variable z and of the small complex parameter ε, where $R_k(z, \varepsilon)$, $k = 1, 2$, are two-by-two matrices holomorphic at $z = \varepsilon = 0$ and D is a constant diagonal matrix. By means of a linear transformation of y and y' the equation (1) is reduced to a simpler equation of the form

$$(2) \qquad \varepsilon^2\{u'' + C_1(\varepsilon)u' + C_2(\varepsilon)u\} = zDu.$$

The method is an adaptation of techniques originating with Langer [Trans. Amer. Math. Soc. **67** (1949), 461–490; MR **11**, 438] and developed further by the author [Funkcial. Ekvac. **4** (1962), 115–139; MR **25** #5240; Arch. Rational Mech. Anal. **13** (1963), 206–221; MR **27** #369]. The first part of the calculation consists of formal operations with series in powers of ε. The proof that these series are asymptotic expansions of functions that effect the desired transformation, even in certain closed regions that contain the turning point $z = 0$, is based on an earlier result by the author [Funkcial. Ekvac. **4** (1962), 83–113; MR **25** #5250]. The transformation so constructed is

different in different sectors of the z-plane. However, as the author proves, the various solutions of (1) obtained in this manner from one solution of (2) are asymptotically equivalent.

There remains the task of solving the simplified equation (2) in a full neighborhood of the turning point. By a skillful use of the fact that these solutions are entire functions of certain auxiliary variables, the author succeeds in determining the values at $z=0$ of a fundamental system of solutions of (2) with known asymptotic expansions for $z\neq 0$.

The last section of the paper contains a brief account of an extension of the method to systems of two third-order equations; this work was done by P. F. Hsieh in his dissertation at the Univ. Minnesota, Minneapolis, Minn., 1964. *W. Wasow* (Madison, Wis.)

Formule di maggiorazione e criteri sufficienti di stabilità per gli integrali di un'equazione differenziale lineare omogenea di ordine *n*.

Atti. Accad. Naz. Lincei Mem. Cl. Sci. Fis. Mat. Natur. Sez. I (8) 7 (1963), 15–31.

In the present paper the author extends to homogeneous linear differential equations of any order

$$(1)\qquad \sum_{k=0}^{n} p_k(t)x^{(n-k)}(t) = 0$$

the criteria of stability previously given for $n=2$ [A. Ghizzetti, Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **33** (1962), 219–229; MR **27** #4996]. First, a comparison theorem is given relating the solutions of (1) with the solutions of an analogous equation with constant coefficients $\sum_{k=0}^{n} q_k y^{(n-k)}(t)=0$ and distinct (real or complex) characteristic roots $\rho_1,\cdots,\rho_n$. Then the criteria of stability of the zero solution as $t\to+\infty$ are given, or of boundedness in $[0,+\infty)$ of each solution with all its derivatives of orders $\leq n-1$. Functions $g(t)$, $t\geq 0$, are defined in terms of the coefficients $p_k(t)$, q_k and roots ρ_s, so that if $g(t)$ is bounded above, then all solutions of (1) are bounded; if $g(t)\to-\infty$ as $t\to+\infty$, then all solutions of (1) approach zero as $t\to+\infty$.

An investigation of non-stationary oscillations in nonlinear systems. (Russian. English summary)

Applications of the methods of non-linear vibrations to the problems of physics and technology (Proc. Internat. Sympos. Non-linear Vibrations, Vol. III, 1961), *pp.* 241–274. *Izdat. Akad. Nauk Ukrain. SSR, Kiev,* 1963.

In this paper the author investigates nonstationary oscillatory processes in nonlinear systems with slowly varying parameters. The author takes into consideration systems, even of high order, of the perturbation type, that is, containing a small parameter ε and reducing to linear ones when $\varepsilon=0$. In these systems not only the external forces may depend on time, together with their frequencies and amplitudes, but also dependent on time are a series of other parameters of the wave system as, for example, the effective mass of the system, the characteristic frequencies and the friction coefficients. In any case, it is assumed that all these parameters vary comparatively slowly. The problem is reduced to the problems studied previously by the author and treated by the Krylov-Bogolyubov-Mitropol'skiĭ method. The problem of passing through resonance in nonlinear systems with one or more degrees of freedom is considered in detail, as well as the problem of passing through parametric resonance. A number of examples are given, taken from physics and technics (resonance phenomena in accelerators, passing through resonance in gyroscopic systems, etc.). Asymptotic expansions of the solutions for ε small are given.

L. Cesari (Ann Arbor, Mich.)

Onuchic, Nelson 4964

Nonlinear perturbation of a linear system of ordinary differential equations.

Michigan Math. J. **11** (1964), 237–242.

Let us consider the systems (1) $\dot x=A(t)x+f(t,x)$, (2) $\dot y=A(t)y$, and denote by $Y(t)$ a fundamental matrix for (2). The author discusses the following problems: (i) If $x(t)$ is a solution of (1), does there exist a constant vector b such that (3) $x(t)=Y(t)[b+O(1)]$ as $t\to+\infty$? (ii) If b is a constant vector, does there exist a solution $x(t)$ of (1) such that (3) holds? Suppose that for every $M>0$ there exists a non-negative function $h_M(t)$ with the property $\|Y^{-1}(t)f(t,Y(t)x)\|\leq h_M(t)$, for all (t,x) such that $t\geq 0$, $\|x\|\leq M$, and $\int_0^\infty h_M(t)dt<+\infty$. Theorem 1: If $x(t)$ is a solution of (1) such that $Y^{-1}(t)x(t)$ is bounded as $t\to+\infty$, then there exists a constant vector b for which (3) holds. Theorem 2: The answer to (ii) is positive. The author considers also the second-order systems $\ddot x=A(t)x+f(t,x)$ and $\ddot y=A(t)y$, where $A(t)=\mathrm{diag}(a_1(t),\cdots,a_n(t))$.

Derguzov, V. I. 4965

Sufficient conditions for the stability of Hamiltonian equations with unbounded periodic operator coefficients. (Russian)

Mat. Sb. (N.S.) **64** (**106**) (1964), 419–435.

Consider the equation (1) $J\,dx/dt=H(t)x$, where x is an element of a complex separable Hilbert space, $J=-J^*$ and J^{-1} are bounded operators, $H(t)$ is a symmetric bounded operator, $H(t+T)=H(t)$, $T>0$ a constant, $H(t)=H_0(t)+H_1(t)$, where $H_0(t)$ is positive definite and $H_1(t)$ is a perturbation term. Both $H_0(t)$ and $H_1(t)$ are subjected to some additional technical assumptions. The concept of a monodromy operator $Y(T)$ of (1) is introduced. Also, the author introduces the concept of a continuously increasing family of operators $H(t,s)$, $0\leq s\leq 1$, which implies by his Theorem 2 that the monodromy operator $Y(T,s)$ of equation (1) with $H_1(t)=H(t,s)$ is such that the spectrum of $Y(T,s)$ is an increasing function of s. The

main theorem is the following: If $H(t, s)$ is a continuously increasing family of operators such that (1) with $H_1(t) = H(t, s)$ is strongly stable for $0 \leq s \leq 1$, then (1) with $H_1(t) = \bar{H}_1(t)$ is strongly stable provided that $H(t, 0) \leq \bar{H}_1(t) \leq H(t, 1)$. This theorem is then applied to the partial differential equation

$$\partial^2 v/\partial t^2 + (EJ^1/m)\partial^4 v/\partial \xi^4 + (1/m)\partial[a(\xi, \theta t)\partial v/\partial \xi]/\partial \xi = 0$$

to obtain limitations on $a(\xi, \theta t)$ to insure stability.

Perov, A. I. 4966

Topological characteristics of solutions of higher-dimensional differential equations. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 791–794.

The author considers the differential equation $dy/dx = Ay$. Here y is a real n-vector in E^n, x is a real m-vector in E^m, and A is a constant linear transformation from E^n to $\mathrm{Hom}(E^m, E^n)$. Assuming certain commutation hypotheses for A, one obtains a unique solution $y(x, \eta)$ satisfying the initial conditions $y(0, \eta) = \eta$. Also $y(x, \eta)$ is continuous in $E^m \oplus E^n$ and satisfies the group property $y(x_1 + x_2, \eta) = y(x_1, y(x_2, \eta))$. Thus the solutions define an action of the vector group E^m on the space E^n. Each orbit is a homomorphic image of E^m; hence the orbits can be classified topologically.

L. Markus (Minneapolis, Minn.)

Fodčuk, V. I. 4967

The existence and properties of the integral manifold of a system of non-linear differential equations with retarded argument and with variable coefficients. (Russian)

Approximate methods of solving differential equations, pp. 129–140. *Izdat. Akad. Nauk Ukrain. SSR, Kiev*, 1963.

Consider the quasi-linear, difference-differential system

$$\begin{aligned} h'(t) &= H(t)h(t) + H_1(t)h(t-\Delta) \\ (1) \qquad &\quad + Q[t, g(t), g(t-\Delta), h(t), h(t-\Delta), \varepsilon], \\ g'(t) &= \omega(t) + P[t, g(t), h(t), \varepsilon], \end{aligned}$$

where h is a vector, g is a scalar, $H(t)$ and $H_1(t)$ are bounded matrices for all t, $\omega(t)$ is a bounded function for all t, and Q and P are small perturbation terms dependent upon a small parameter ε. For the corresponding ordinary differential system ($\Delta = 0$), Mitropol'skiĭ [Ukrain. Mat. Ž. **10** (1958), 270–279; MR **21** #176a] has given conditions for the existence of an asymptotically stable integral manifold. The present author shows that the conditions and ingenious proof, due to Bogoljubov and Mitropol'skiĭ, can be adapted to the system with a delay ($\Delta > 0$).

The author does not state his results too clearly, but apparently what he proves is the following. Assume appropriate conditions of continuity, Lipschitz continuity, smallness of P and Q when h and ε are small, and exponential asymptotic stability of the trivial solution of $h'(t) = H(t)h(t) + H_1(t)h(t-\Delta)$. Then there exists a function $f(t, g, \varepsilon)$ such that, given any (t_0, g_0), if $g(t)$ is the (unique) solution of $g'(t) = \omega(t) + P[t, g(t), f(t, g(t), \varepsilon), \varepsilon]$ with $g(t_0) = g_0$ and if $h(t) = f(t, g(t), \varepsilon)$ on $[t_0 - \Delta, t_0]$, then $g(t)$ and $h(t) = f(t, g(t), \varepsilon)$ satisfy (1) for all t. Moreover, if $g(t)$, $h(t)$ is any solution of (1) for $t > t_0$ with $h(t) = \varphi(t, \varepsilon)$ on $[t_0 - \Delta, t_0]$, where $|\varphi(t, \varepsilon)|$ is sufficiently small, then $|h(t) - f(t, g(t), \varepsilon)| \to 0$ exponentially as $t \to \infty$.

Kapilevič, M. B. 4971

Singular Goursat problems in a neighborhood of a singular characteristic at zero and at infinity. (Russian)

Dokl. Akad. Nauk SSSR **137** (1961), 1287–1290.

The author considers the equation

$$(1) \qquad L(z, B, C) = xz_{xy} + A(x)z_x + B(x)z_y + C(x)z = 0$$

in the domain D $(0 \leq x \leq x_0,\ 0 \leq y \leq y_0)$ where $A(x) > 0$ and $B(x)$, $C(x)$ are C^2 functions in X $(0 \leq x \leq x_0)$. Let $z(x, y, B, C)$ denote a twice continuously differentiable solution of (1)

in D, for which (2) $z(0,y)=f(y)$, $z(x,0)=0$, $f(0)=0$. As in an earlier paper [same Dokl. **130** (1960), 487–490; MR **22** #11208], the author assumes that $f(y)\in C_y^q$ on Y $(0\le y\le y_0)$ on the y-axis.

A typical result announced by the author is the following. Let $z(x,y,b+n+1)$ be a solution of the problem $z(0,y)=(-a)^{-n-1}(b)_{n+1}f^{(n+1)}(y)$, $z(x,0)=0$ for the equation $L(z,b+n+1)=0$, where $f(y)\in C_{n+3}^{n+1}$. Then

$$z(b)=\sum_{k=0}^{n}\frac{(b)_k}{k!}\left(-\frac{x}{a}\right)^k f^{(k)}(y)+\frac{1}{n!}\int_0^x (x-\xi)^n z(\xi,y,b+n+1)\,d\xi.$$

A. J. Lohwater (Providence, R.I.)

Beals, Richard 4972

Nonlocal elliptic boundary value problems.

Bull. Amer. Math. Soc. **70** (1964), 693–696.

Let A be a properly elliptic operator of order $2p$ in a region $G\subseteq E^n$, and let B_j be a differential operator of order j defined on the boundary ∂G of G, $0\le j<2p$. The boundary-value problems considered are of the form

$$(1)\qquad Au=f \quad \text{in } G,$$

$$(2)\qquad B_k u=\sum_{j\in J} C_{kj}B_j u \quad \text{on } \partial G,\qquad k\in K,$$

where J and K are complementary subsets of $\{0,1,\cdots,2p-1\}$ and (C_{kj}) are arbitrary operators bounded in a certain sense. The operator $A(C)$ is defined as the restriction of A to those distributions u such that $Au\in L^2(G)$, such that distribution derivatives of orders $<2p$ have L^2 boundary values on ∂G, and such that (2) holds. Sufficient conditions are obtained for $A(C)$ to be closed and have its domain in $W^{2p,2}(G)$. The formal adjoint $A'(C')$ of $A(C)$ is defined, and sufficient conditions are given for them to be true adjoints. Information about the spectrum of $A(C)$ is given for second-order operators. The paper gives generalizations of some results of Bade and Freeman [Pacific J. Math. **12** (1962), 395–410; MR **29** #2421].

M. Schechter (New York)

Ladyženskaja, O. A.; Rivkind, V. Ja.; Ural'ceva, N. N. 4973

Classical solvability of diffraction problems for equations of elliptic and parabolic types. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 513–515.

Les auteurs énoncent deux théorèmes sur la régularité de la solution du problème de transmission pour l'opérateur elliptique et parabolique du deuxième ordre sous des hypothèses assez faibles pour les coefficients, le domaine et les données. La solution en question est höldérienne jusqu'à la frontière; c'est le cas pour les premières dérivées dans les domaines de continuité des coefficients et du second membre à l'exception eventuelle des points de contact des surfaces de discontinuité des coefficients.

J. Nečas (Prague)

Tutschke, Wolfgang 4974

Über periodische Lösungen nicht notwendig selbstadjungierter elliptischer Differentialgleichungssysteme in mehrfach-zusammenhängenden Gebieten.

Math. Nachr. **26** (1963/64), 247–286.

The author discusses the system

$$\frac{\partial u^*}{\partial x_2}=a_{11}(x_1,x_2)\frac{\partial u}{\partial x_1}+a_{12}(x_1,x_2)\frac{\partial u}{\partial x_2}+\frac{\partial z}{\partial x_2}u,$$

$$-\frac{\partial u^*}{\partial x_1}=a_{21}(x_1,x_2)\frac{\partial u}{\partial x_1}+a_{22}(x_1,x_2)\frac{\partial u}{\partial x_2}-\frac{\partial z}{\partial x_1}u,$$

where z has additive periods along the boundary curves and u^* has only additive periods. In a multiply connected domain there corresponds to the differential operator

$$\sum_{i,j}\frac{\partial}{\partial x_i}\left(a_{ij}\frac{\partial u}{\partial x_j}\right)+\sum_k e_k\frac{\partial u}{\partial x_k}=0$$

an integrating factor μ with constant boundary values so that $\mu\cdot L\equiv\sum_{i,j}\partial(\hat a_{ij}\,\partial/\partial x_j)/\partial x_i$ can be reduced to Bianchi normal form. μ is different from zero in all of $\bar G$ and is uniquely determined up to a constant factor.

L'auteur considère Ω_ε, les domaines plans, à frontière Γ_ε, aux cartes polaires sous la forme $\rho=1+\varepsilon\alpha(\varphi)$, où α est une fonction analytique à periode 2π et le problème

$$(1)\qquad L_\varepsilon u_\varepsilon\equiv\Delta u_\varepsilon+a\frac{\partial u_\varepsilon}{\partial x}+b\frac{\partial u_\varepsilon}{\partial y}+cu_\varepsilon=f$$

avec a,b,c,f des fonctions analytiques dans Ω_ε et avec la condition aux limites

$$(2)\qquad u_\varepsilon|_{\Gamma_\varepsilon}=0.$$

Si le problème (1), (2) pour $\varepsilon=0$, $f\equiv0$ n'a qu'une solution triviale, la solution de (1), (2) se trouve sous la forme $u=u_0+\varepsilon u_1+\cdots+\varepsilon^n u_n+\cdots$, où $L_0u_0=f$, $u_0|_{\Gamma_0}=0$, $L_0u_n=0$, $u_n|_{\Gamma_0}=-\sum_{l=1}^n(\alpha^l/l!)\,D^{(l)}u_{n-l}$, $n=1,2,\cdots$, et $D^{(l)}$ est la dérivée selon la normale.

L'auteur considère encore le cas, où (1), (2) a une solution propre. Puis, on cherche des valeurs et fonctions propres, à savoir u_ε, λ_ε de sorte que $L_\varepsilon u_\varepsilon-\lambda_\varepsilon u_\varepsilon=0$, $u_\varepsilon|_{\Gamma_\varepsilon}=0$. Si λ_0 est simple, λ_ε, u_ε s'expriment sous la forme $\lambda_\varepsilon=\sum_{n=0}^\infty\varepsilon^n\lambda_n$, $u_\varepsilon=\sum_{n=0}^\infty u_n\varepsilon^n$ avec

$$L_0u_0-\lambda_0u_0=0,\qquad u_0|_{\Gamma_0}=0,$$

$$L_0u_n - \lambda_0 u_n = \sum_{k=1}^{n} \lambda_k u_{n-k}, \quad u_n|_{\Gamma_s} = -\sum_{l=1}^{n} (\alpha^l/l!)D^{(l)}u_{n-l},$$

$n = 1, 2, \cdots$; les fonctions $u_0, u_1, \cdots$ sont d'une certaine manière normées. *J. Nečas* (Prague)

Pulvirenti, Giuseppe 4978
Ancora sui problemi ai limiti per l'operatore di Laplace iterato.
Matematiche (*Catania*) **18** (1963), 108–116.

A study is made of the solution of

$$\Delta^2 u + \lambda u = f \quad \text{in } \Omega,$$
$$\Delta u = g_0 \quad \text{on } \Gamma,$$
$$\gamma_1(\Delta u) = g_1 \quad \text{on } \Gamma,$$

where Ω is a bounded domain in R^n with C^∞ boundary Γ, γ_1 is the normal derivative on Γ. This boundary-value problem is not coercive, since the boundary conditions do not cover Δ^2. Therefore the usual results for such problems do not hold. It is shown that if $f \in L^2(\Omega)$, $g_0 \in H^{r-1/2}(\Gamma)$, $g_1 \in H^{r-3/2}(\Gamma)$ for $-2 \leq r < 2$, there does not always exist a solution $u \in L^2(\Omega)$ such that $\Delta u \in H^r(\Omega)$. Necessary and sufficient conditions for existence are given. On the other hand, if $f \in H^{r-2}(\Omega)$, $g_0 \in H^{r-1/2}(\Gamma)$, $g_1 \in H^{r-3/2}(\Gamma)$ for $r \geq 2$, then there exists a unique solution $u \in H^{r-2}(\Omega)$ such that $\Delta u \in H^r(\Omega)$. *M. Schechter* (New York)

Redheffer, R. M.; Straus, E. G. 4979
Degenerate elliptic equations.
Pacific J. Math. **14** (1964), 265–268.

The authors obtain the following main result (Theorem 2). Let u be differentiable in B, a region in E^n, and have continuous second derivatives except on the union of countably many smooth surfaces. (Here, a smooth surface means the set of zeros of a C^2 function.) If the conditions

(1) $\quad \sum a_{ij}(x)u_{ij}(x) \geq 0, \qquad (a_{ij}) \geq 0, \ (a_{ij}) \neq 0,$

hold on a dense subset of B, then u satisfies the maximum principle, i.e., if E is any compact subset of B, we have

$$\sup_{x \in E} u(x) \leq \sup_{x \in \partial E} u(x).$$

The whole problem here, of course, is that u might conceivably have a local maximum at a singular point, i.e., a point where either u fails to have continuous second derivatives or where (1) fails to hold. The authors show that in that case a C^2 function θ may be constructed such that $(\theta_{ij}) > 0$, and such that the function $\tilde{u} = u + \theta$ must then have a local maximum at a non-singular point, thereby violating the classical maximum principle.
Stanley Kaplan (Pisa)

Vekilov, Š. I. 4980
An application of potential theory to the solution of Dirichlet problems for an elliptic equation in a domain with corners. (Russian. Azerbaijani summary)
Izv. Akad. Nauk Azerbaĭdžan. SSR Ser. Fiz.-Mat. Tehn. Nauk **1963**, *no.* 6, 11–16.

L'auteur résout le problème de Dirichlet classique pour l'opérateur elliptique du deuxième ordre

$$\sum_{i,j=1}^{3} \frac{\partial}{\partial x_i}\left(a_{ij}\frac{\partial}{\partial x_j}\right)$$

à coefficients assez réguliers dans un domaine borné à trois dimensions dont la frontière Γ satisfait à la condition de Ljapunov sauf sur une courbe $L \subset \Gamma$, assez régulière, formant une arête angulaire. La solution se cherche en potentiel d'une double couche. Le problème est ainsi réduit à l'équation intégrale $\mu(x) + (1/2\pi)\int_\Gamma Q(x,\xi)\mu(\xi)d\Gamma_\xi = f(x)$. Le noyau $Q(x,\xi) = G(x,\xi) + G_1(x,\xi) + R_1(x,\xi)$ avec R_1 borné, $\int_\Gamma |G_1(x,\xi)|d\Gamma_\xi$ arbitrairement petit, $\int_\Gamma |G(x,\xi)|d\Gamma_\xi \leq \kappa < 1$. On peut alors appliquer l'alternative de Fredholm et obtenir par la méthode de T. Carleman la solution unique. On considère encore l'opérateur elliptique général du deuxième ordre. *J. Nečas* (Prague)

Mihaĭlov, V. P. 4981
The first boundary-value problem for certain semi-bounded hypo-elliptic equations. (Russian)
Mat. Sb. (*N.S.*) **64 (106)** (1964), 10–51.

Consider the differential equation

(1) $\quad P(u) = \sum_{(\alpha)=1} A^\alpha(x)D^\alpha u + \sum_{(\alpha)<1} A^\alpha(x)D^\alpha u = f(x),$

where $x = (x_0, x_1, \cdots, x_n)$ varies in a closed domain $\bar{Q}$, $\alpha = (\alpha_0, \alpha_1, \cdots, \alpha_n)$, $(\alpha) = \alpha_0/(2m_0+1) + \sum_{i=1}^n (\alpha_i/2m_i)$, and assume that $\operatorname{Re} \sum_{(\alpha)=1} A^\alpha(x)(i\xi)^\alpha \geq \theta^2(\xi_1^{2m_1} + \cdots + \xi_n^{2m_n})$ $(\theta^2 > 0)$, $A^{(2m_0+1,0,\cdots,0)}(x) \neq 0$ in $\bar{Q}$. Assume also that $2m_0 + 1 < 2m = 2\max_{1 \leq i \leq n} m_i$, that the boundary Γ of Q consists of portions Γ_i $(i = 0, \cdots, n)$ lying on $x_i =$ const and

of a complementary set Γ, and that at two points a, b of Γ the tangent (to Γ) is of the form $x_0 = \text{const}$, and one of the cylinders $|x_i - x_i^c| = C_0|x_0 - x_0^c|^p$ is contained in a Γ-neighborhood of c for $c = a$, $c = b$, where p is any number $> (2m_0+1)/2m$. Together with (1) consider the boundary conditions (2) u vanishes on $\hat{\Gamma}$ together with all its first $m-1$ derivatives, (3) $\partial^j u/\partial x_i^j = 0$ on Γ_i for $j = 0, 1, \cdots, m_i - 1$ and $i = 0, 1, \cdots, n$. For the special case $m_0 = 1$, $m_1 = \cdots = m_n$, (1) is parabolic and the existence and uniqueness of a solution of (1)–(3) were established by the author in previous works [see, for example, same Sb. (N.S.) **63** (105) (1964), 238–264; MR **29** #369]. In the present paper the author establishes analogous results for (1)–(3). He employs an extended Gårding inequality to reduce the problem (1)–(3) (or rather, a weaker version of it) to a Fredholm alternative and then uses the conditions on Γ to establish uniqueness (which implies existence). Equations other than (1) are also treated by the same method. *A. Friedman* (Evanston, Ill.)

Èidus, D. M. 4982

On the limiting amplitude principle. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 794–797.

Let H be a Hilbert space, G a self-adjoint operator in H, $G > 0$, R_z the resolvent of G, and H_0 a subspace of H with associated orthogonal projection P. Let $w(t)$ take values in H with $d^2w/dt^2 + Gw = f\exp(-i\sqrt{(\lambda t)})$, $w|_{t=0} = 0$, and $dw/dt|_{t=0} = 0$, for $\lambda > 0$, $f \in H$, where w' is continuous on $0 \leq t < \infty$ and w'' on $0 < t < \infty$. Suppose for any $\sigma > 0$, $\lim PR_z f = v^+(\sigma)$ exists for $z \to \sigma$ when $\operatorname{Im} z > 0$ and $\lim PR_z f = v^-(\sigma)$ exists for $z \to \sigma$ when $\operatorname{Im} z < 0$, and suppose the function $\theta(\sigma) = v^+(\sigma) - v^-(\sigma)$ satisfies a Hölder condition on any interval $a \leq \sigma \leq b$, $a > 0$. Then, for example, if $\|\theta(\sigma)\| \leq c\sigma^{-\alpha}$ for $0 < \sigma \leq \delta$, $0 \leq \alpha < \frac{1}{2}$, it follows that $\exp(i\sqrt{(\lambda t)})Pw \to v^+(\lambda)$ as $t \to \infty$ (for any $\lambda > 0$). Various other limiting results as $t \to \infty$ for Pw, Pw', and Pw'' are also obtained under various hypotheses on θ.

Next the author considers the equation $\partial^2 w/\partial t^2 + gw = \exp(-i\sqrt{(\lambda t)})f(x)$ in an unbounded region $\Omega \subset \mathbf{R}^n$ under zero initial and homogeneous boundary conditions. Here $\lambda > 0$ and g is an elliptic differential operator of order $2m$. One says that the principle of limiting amplitudes holds for this equation if $\lim \exp(i\sqrt{(\lambda t)})w = v$, where v is the solution of $gv = \lambda v + f$. Various aspects of this problem are then studied under suitable hypotheses, and a number of interesting results are stated. *R. Carroll* (Urbana, Ill.)

Huet, Denise 4983

Perturbations singulières.

C. R. Acad. Sci. Paris **258** (1964), 6320–6322.

Let u_ε be the solution of a boundary-value problem of the form

$$-\varepsilon Au + u = h_\varepsilon \quad \text{in } \Omega,$$

$$B_j u = g_j \quad \text{on } \Gamma, \qquad 1 \leq j \leq m,$$

where Ω is a bounded domain in R^n with smooth boundary Γ, A is a properly elliptic operator of order $2m$, and $\{B_j\}$ is a normal set of differential boundary operators which not only covers A but satisfies an extended condition of Agmon [Comm. Pure Appl. Math. **15** (1962), 119–147; MR **26** #5288], which guarantees that the positive real axis is a ray of minimal growth of the resolvent in $L^p(\Omega)$ for the corresponding homogeneous problem. It is shown that if $h_\varepsilon \to h$ in $L^p(\Omega)$, $1 < p < \infty$, then $u_\varepsilon \to h$ in $L^p(\Omega)$, $\varepsilon u_\varepsilon \to 0$ in $W_p^{2m}(\Omega)$ as $\varepsilon \to 0$ whenever the g_j are in a suitable space. Moreover, for $r \geq 0$ ($r - 1/p$ not an integer for $p \neq 2$), if $h_\varepsilon \to h$ in $W_p^r(\Omega)$, then $u_\varepsilon \to h$ in $W_p^r(\mathfrak{A})$ and $\varepsilon u_\varepsilon \to 0$ in $W_p^{2m+r}(\mathfrak{A})$ as $\varepsilon \to 0$ for any compact subset $\mathfrak{A}$ of Ω.

M. Schechter (New York)

Jakut, L. I. 4984

Theorems of Lax for non-linear evolutionary equations. (Russian)

Dokl. Akad. Nauk SSSR **156** (1964), 1304–1307.

Consider the nonlinear equation (*) $du/dt + A(t)u = \varphi(t, u)$ ($t \in \langle 0, T\rangle$) with the initial-value problem $u(0) = u_0$. Let $A(t)$, for every $t \in \langle 0, T\rangle$, be a closed linear operator from its domain $D(A) \subset E$ into a Banach space E. Assume that $D(A)$ does not depend on t, is dense in E, and, for every λ such that $\operatorname{Re}\lambda \geq 0$, the resolvent $(A(t)+\lambda I)^{-1}$ exists and $\|(A(t)+\lambda I)^{-1}\|_E \leq C/(|\lambda|+1)$ for $t \in \langle 0, T\rangle$.

Assume that there are given two Banach spaces E_1 and E_2 such that $E_2 \subset E_1 \subset E$, $D(A^\alpha(t)) \subset E_2$ and $\|v\|_{E_2} \leq C_1\|A^\alpha(t)v\|_E$ for some $\alpha > 0$ ($v \in D(A^\alpha(t))$). Let there exist a sequence of linear continuous operators $A_n(t)$ from the space E_2 into itself such that

$$\sup\{\|(A_n(t) - A(t))A^{-1}(t)v\|_{E_1} : t \in \langle 0, T\rangle\} \leq \rho_n\|v\|_{E_2}$$

for $v \in E_2$, where $\rho_n \to 0$. Assume that $L_n = \{v \in E_2 : A_n(t)v = 0\}$ does not depend on t. Assume that there exists a seminorm $\|v\|_n$ on the space E_2 such that (1) $\|v\|_n = 0$ if and only if $v \in L_n$; (2) $\|v\|_n \leq C_2\|v\|_{E_1}$ for $n = 1, 2, \cdots$ and $v \in E_2$; (3) $\|v\|_n \leq \|v\|_E + \varepsilon_n\|v\|_{E_2}$ ($\varepsilon_n \to 0$). Let S_n be the quotient space E_2/L_n with the norm $\|\bar{v}\|_{S_n} = \inf\{\|v\|_{E_1} : v \in \bar{v}\}$, where $\bar{v}$ is the coset containing v, and (4) let $\|\bar{v}\|_{S_n} \leq (1/\gamma_n)\|\bar{v}\|_n$ for $\bar{v} \in S_n$, where $\gamma_n \to 0$. Define an operator $\overline{A(t)}$ in the space S_n by the formula $\overline{A_n(t)}\bar{v} = \overline{A_n(t)v}$. Let $\varphi(t, v)$ be such that, for every fixed t, the set $\{\varphi(t, v) : v, \bar{v} \in S_n, \|v\|_{E_2} < R_2\}$ is contained in a coset of the quotient space $E_2/L_n = S_n$.

Consider the finite-difference equation corresponding to the equation $(\bar{v}_{k+1} - \bar{v}_k)/\Delta_n t + \overline{A_n(k\Delta_n t)}\bar{v}_k = \bar{\varphi}_k$, $\bar{v}_0 = \bar{u}_0$, where $\bar{\varphi}_k = \overline{\varphi(k\Delta_n t, v_k)}$ and $v_k \in \bar{v}_k$. Theorem: Let $u(t)$ be a solution of the equation (*). Assume $u_0 \in D(A^{1+\gamma_2}(0))$, $\varphi(0, u_0) \in D(A^{\gamma_2}(0))$; let $\varphi(t, u(t))$ be bounded in the norm of the space E_2 and continuously differentiable in the space E. Let $\|\varphi(t, v) - \varphi(t, w)\|_n \leq C\|v - w\|_n$ for $t \in \langle 0, T\rangle$ and $v, w \in K$, where $K = \{v \in E_1 : \|v\|_{E_1} \leq R\}$ and $K \ni u(t)$ for all $t \in \langle 0, T\rangle$. Let $A(t)A^{-1}(0)$ be strongly continuously differentiable in E and $\|I - \Delta_n t\bar{A}_n(t)\|_n \leq 1 + C\Delta_n t$ for $t \in \langle 0, T\rangle$. If $\varepsilon_n \Delta_n t^{\gamma_2 - \gamma_1} = O(\gamma_n)$, $\rho_n = O(\gamma_n)$, $\Delta_n t^{\gamma_2} = O(\gamma_n)$ ($0 < \alpha = \gamma_1 < \gamma_2 < 1$), then the solution of the finite-difference equation $v_n(t)$ converges in the norm of S_n to $u(t)$ uniformly on the interval $\langle 0, T\rangle$.

Similar results are announced for the equation of the form $du/dt + B(t, u)u = 0$. An application to quasi-elliptic equations is given. *W. Bogdanowicz* (Washington, D.C.)

Kostjučenko, A. G. 4985

The asymptotic distribution of eigenvalues of elliptic operators. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 41–44.

The principal result announced concerns the distribution of the eigenvalues of

$$(1)\quad L=(-1)^m\sum_{k_1+\cdots+k_n=2m}A^{k_1,\cdots,k_n}(x)\frac{\partial^{2m}}{\partial x_1^{k_1}\cdots\partial x_n^{k_n}}+L_1\left(x,\frac{\partial}{\partial x}\right)+q(x)$$
$$=L_0+L_1+q(x),$$

where $x=(x_1,\cdots,x_n)$, $-\infty<x_i<\infty$. L_0 is uniformly elliptic in R_n, with uniformly Hölder-continuous coefficients; L_1 is of order $<2m$ with bounded coefficients; and as $|x|\to\infty$, $q(x)\to\infty$ restricted by a number of conditions. If $N(\lambda)$ denotes the number of eigenvalues of L less than λ, then

$$(2)\quad N(\lambda)\sim\frac{1}{(2\pi)^n\Gamma\left(\dfrac{n}{2m}+1\right)}\int_{q(x)<\lambda}\Phi(x)(\lambda-q(x))^{n/2m}\,dx,$$

where $\Phi(x)=\int_{R_n}e^{-L_0(x,s)}\,ds$.

The proof outlined starts with the parabolic equation $\partial v/\partial t=-Lv$ and proceeds to estimates on the fundamental solution $G(x,y,t)$ via the parametrix method. The identity $\int_{R_n}G(x,x,t)\,dx=\int_0^\infty e^{-\lambda t}dN(\lambda)$ and a Tauberian theorem are then used to obtain (2).

{Line 7, p. 42, should read "$(\det\|a_{ij}(x)\|)^{-1/2}$" and in line 15, p. 43, a term $L_1(y,\partial/\partial x)$ should be added inside the brackets.} *R. E. L. Turner* (Madison, Wis.)

Mangeron, D.; Krivošein, L. E. 4986

Problemi di Goursat e di Dirichlet per una classe di equazioni integro-differenziali a derivate totali. (English summary)

Rend. Accad. Sci. Fis. Mat. Napoli (4) **28** (1961), 213–224.

Authors' summary: "Some theorems are presented concerning the problems of Goursat and Dirichlet and for the class of integro-differential equations with total derivatives, where, analogously with the novel aspects of the theorems established by one of the authors [cf., e.g., D. Mangeron, Mathematica (Cluj) **14** (1938), 31–35] for the boundary-value problems $[A(x)u'+\lambda B(x)u]'+\lambda[B(x)u'+C'(x)u]=0$, $u|_{FR}=0$, $R(x_i'\leq x_i\leq x_i'')$, the symbol $'$ designates total differentiation in the sense of Picone: $u'=\partial^{2n}u/\partial x_1\partial x_2\cdots\partial x_{2n}$."

Ossicini, A. 4987

Sugli integrali doppi di espressioni lineari alle derivate parziali del 4° ordine.

Rend. Mat. e Appl. (5) **21** (1962), 100–124.

In this paper the author characterizes the operators

$$E=\sum_{s=0}^{4}\sum_{h+k=s}a_{hk}(x,y)\frac{\partial^s}{\partial x^h\partial y^k}$$

and the domains T of the plane such that the double integral

$$\Phi(u)=\iint_T E(u)\,dx\,dy$$

depends only on the values of u and its partial derivatives up to the second order at the angular points of the boundary $\mathcal{F}T$ of T. Such functionals are called point-functionals. A. Ghizzetti solved the same problem for operators of second and third order [Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **22** (1957), 276–281; MR **19**, 1061; ibid. (8) **22** (1957), 430–433; MR **19**, 1061]. The author proves first that the boundary $\mathcal{F}T$ must be composed only of arcs of characteristic curves of the operator E. Therefore the author assumes that T is bounded by characteristic curves. He considers four cases in which the four systems of characteristic curves are real, with at least two of them different; consequently, he sets $a_{40}=a_{04}=0$. Then he gives necessary and sufficient conditions (one on T and three on $\mathcal{F}T$) in order that Φ be a point-functional. If $\mathcal{F}T$ consists only of parallels to the axes, then the author proves that a linear partial differential operator of second order F exists such that

$$\Phi(u)=\int_{x_0}^{x_1}\int_{y_0}^{y_1}\frac{\partial^2F(u)}{\partial x\partial y}\,dx\,dy=$$
$$[F(u)]_{P_0}-[F(u)]_{P_1}+[F(u)]_{P_2}-[F(u)]_{P_3},$$

where $P_0(x_0,y_0)$, $P_1(x_1,y_0)$, $P_2(x_1,y_1)$, $P_3(x_0,y_1)$ are the angular points of $\mathcal{F}T$. The author considers also the subcases in which $\mathcal{F}T$ consists of arcs belonging to three or four different systems of characteristic curves. Thus the arbitrariness of the coefficients of $F(u)$ is greatly reduced. In all cases typical examples are given. The method makes use of the formulae

$$E(u)=\frac{\partial A(u)}{\partial x}+\frac{\partial B(u)}{\partial y}+R\cdot u,$$

$$\Phi(u)=\sum_{i=1}^{q}\int_{\gamma_i}\left[\sum_{j=0}^{3}\sum_{h+k=j}C_{hk}\frac{\partial^j u}{\partial s^h\partial n^k}\right]ds+\iint_T R\cdot u\,dx\,dy,$$

with A, B, R, C_{hk} conveniently defined and where s is the arc, n the normal and q the number of regular arcs γ_i of the boundary $\mathcal{F}T$. *A. Dou* (Madrid)

Šilov, G. E. 4988

Well-posed boundary-value problems in a half-space for linear partial differential equations with constant coefficients. (Russian)

Uspehi Mat. Nauk **19** (1964), no. 3 (117), 3–52.

This is primarily an expository paper. Consider the equation (1) $P(D_t,D_x)u=0$ for $x\in R^n$, $t>0$, where $D_t=\partial/\partial t$, D_x is any partial x-derivative and assume that $P(\lambda,\sigma)$ is a polynomial in λ,σ of degree m in λ, and $P(\lambda,\sigma)=\lambda^m+$lower order terms in λ. The Cauchy problem for (1) consists of finding a solution subject to initial conditions of the form $\partial^j u(x,0)/\partial t^j=\varphi_j(x)$ $(j=0,\cdots,m-1)$. This problem always has a unique solution provided the φ_j and u belong to suitable classes of functions (depending on P). The purpose of the present paper is to prove (under suitable initial conditions) existence and uniqueness of solutions in $0<t<\infty$ under the following requirements: (a) For each $t>0$, $u(x,t)$ belongs to a space $\mathcal{K}$ (independent of P), (b) $D_t^ju(x,t)$ $(j=0,\cdots,m-1)$ are bounded in $\mathcal{K}$ by $O(t^h)$ as $t\to\infty$, where h may depend on u. It should be noted that in the Cauchy problem the solution may not exist beyond some finite interval $0\leq t\leq T$. $\mathcal{K}$ is defined as the Fourier transform of H, where H is the union space

of spaces H_j $(j=1, 2, \cdots)$ and H_j consists of all the integrable functions $g(x)$ with finite norm

$$|g|_{j} = \left\{ \int_{E^n} |g(x)|^2 (1+|x|^2)^{-j} \, dx \right\}^{1/2}.$$

The main result is the following. Let $\operatorname{Re} \lambda_0(\sigma) \leq \cdots \leq \operatorname{Re} \lambda_{m-1}(\sigma)$, where $\lambda_j(\sigma)$ are the zeros of $P(\lambda, \sigma)=0$, and let A_j consist of the points σ for which $\operatorname{Re} \lambda_{j-1}(\sigma) \leq 0 < \operatorname{Re} \lambda_j(\sigma)$. Assume that on each A_j $(j=0, \cdots, m-1)$ there is given a function $\nu_j(\sigma)$ which can be extended to an element of H. Then there exists a unique solution of (1) which satisfies (a), (b) and the following conditions: The Fourier transform of $\partial^j u(x, 0)/\partial t^j$ $(j=0, \cdots, m-1)$ coincides with $\nu_j(\sigma)$ on A_j. If the $\operatorname{Re} \lambda_j(\sigma)$ do not change sign, then the solution can be represented in terms of fundamental solutions. Explicit formulas for these fundamental solutions are given in the case of homogeneous equations.

Adler, G. 4989

Majoration du gradient des solutions de l'équation $\Delta u - a u_t' = f$. II.

Acta Math. Acad. Sci. Hungar. **15** (1964), 259–283.

This is a continuation of a previous paper [same Acta **15** (1964), 137–152; MR **28** #4235]. Estimates of $|\operatorname{grad} u|$ are found for solutions of the equations $\Delta u - a u_t' = 0$, $\Delta u = f$, and $\Delta u - a u_t' = f$, under various sets of hypotheses concerning the domain and the data relative to initial and boundary conditions. The results involve much intricate detail, and consequently no summary of them can be given here.

L. A. MacColl (New York)

Kopaček, Irži [Kopáček, Jiří] 4990

Solution of the Cauchy problem for linear hyperbolic equations by the method of finite differences. (Russian. English summary)

Czechoslovak Math. J. **14** (89) (1964), 52–78.

Let (1) $a(x, D)u = g$ be a linear strictly hyperbolic equation of arbitrary order with variable coefficients. (Here u is supposed to be periodic in the space variables.) It has been proved [Gårding, *La théorie des équations aux dérivées partielles*, pp. 71–90, Centre Nat. Rech. Sci., Paris, 1956; MR **22** #6937] that there exists a unique solution $u \in H_0^{m+1, n-1}$ to the corresponding Cauchy problem if $g \in H^{0,n}$, and if the coefficients of $a(x, D)$ belong to Lip^n $(n \geq 1)$. The proof was based on the construction of an a priori (Friedrichs-Lewy) inequality for the given Cauchy problem and of a similar inequality in the dual norms for an adjoint problem.

The present paper closely follows Gårding's in the construction of a (discrete) F.L. inequality for the explicit difference equation (2) $a(x, \Delta)u = g$, where $a(x, \Delta)$ is obtained from $a(x, D)$ by the substitution of a centered difference operator Δ in the place of D. Then it is proved that this discrete F.L. inequality is sufficient to ensure the weak convergence, with decreasing mesh width, of the solutions of (2) to a solution $u \in H_0^{m+1, n-1}$ of (1), provided the mesh ratio is bounded. The regularity assumptions are the same as in Gårding's paper (or slightly weaker). The author also considers an implicit difference scheme of the same type. A preliminary report of these results was given in Dokl. Akad. Nauk SSSR **141** (1961), 551–554; [MR **24** #A2756].

J. Friberg (Lund)

Mel'nik, Z. O. 499

A mixed problem for certain hyperbolic systems. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 314–318.

The author considers the problem

$$\sum_{k_0+\cdots+k_n=4} a^{i}_{k_0,\cdots,k_n}(x, t)\, \partial^4 u_i / \partial t^{k_0} \partial x_1^{k_1} \cdots \partial x_n^{k_n} + \sum_{s=1}^{N} \sum_{k_0+\cdots+k_n<4} a^{i,s}_{k_0,\cdots,k_n}(x, t)\, \partial^{\Sigma k_i} u_s / \partial t^{k_0} \cdots \partial x_n^{k_n} = f_i(x, t)$$

in a region $\Omega = [0, T] \times D$, $D \subset \mathbf{R}^n$, with $\partial^m u_i / \partial t^m |_{t=0} = 0$ $(m \leq 3;\ 1 \leq i \leq N,\ x \in \bar{D})$ and $u_i|_S = \partial u_i / \partial \nu|_S = 0$ $(1 \leq i \leq N,\ 0 \leq t \leq T)$, where S is the (smooth) boundary of D, and the system is hyperbolic. Under suitable hypotheses using a method of Gårding, existence and uniqueness are proved, and an estimate $\|u\|_{W_2^3} \leq c \|f\|_{L^2}$ is obtained. Also a second-order hyperbolic system is considered.

R. Carroll (Urbana, Ill.)

Peyser, Gideon 499

The Goursat problem for hyperbolic equations.

J. Math. Mech. **10** (1961), 91–109.

The author considers the linear partial differential equation

$$(\alpha_1 \partial/\partial x + \beta_1 \partial/\partial y) \cdots (\alpha_m \partial/\partial x + \beta_m \partial/\partial y) u + \cdots = f,$$

where $x \in [0, x_0]$, $y \in [0, y_0]$, $\alpha_i = \alpha_i(x, y)$, $\beta_i = \beta_i(x, y)$, $\alpha_i^2 + \beta_i^2 = 1$, and

$$\infty > \frac{\alpha_1}{\beta_1} > \cdots > \frac{\alpha_k}{\beta_k} > 0 \geq \frac{\alpha_{k+1}}{\beta_{k+1}} > \cdots > \frac{\alpha_m}{\beta_m} \geq -\infty \qquad (k \leq m)$$

On the lines $y=0$ and $x=0$ linear boundary conditions of order $m-1$ are prescribed for $k+r$ and $m-r$, respectively, where r is given, $0 \leq r \leq m-k$; $u_{x^i y^j}(0, 0)$ are also given $(i+j \leq m-2)$. Under well-defined smoothness hypotheses on the coefficients and under sufficiently broad hypotheses on homogeneous terms in the problem (and also under certain natural hypotheses of an algebraic character on the operators in question) the author proves the existence and uniqueness of a generalized, and thus of a classical solution. We remark that under the conditions imposed on the characteristics, each of the two non-strict inequalities is assumed to be strict on the y-axis and the x-axis respectively, or else to be the identity, i.e., the author considers the non-characteristic and the characteristic problems. The work is based on an energy inequality and on one related to it which was derived in an earlier paper of the author [same J. **6** (1957), 641–653; MR **19**, 1059].

The author should also make reference to Campbell and Robinson [Proc. London Math. Soc. (3) **5** (1955), 129–147; MR **16**, 1116].

A. D. Myškis (RŽMat **1961** #10 B214)

Makai, E. 499

On the fundamental frequencies of two and three dimensional membranes. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 109–123.

The author obtains new isoperimetric inequalities for the first eigenvalue (square of the fundamental frequency) in the three-dimensional membrane problem defined on a domain D whose outer boundary S_0 of surface area S is

convex. The domain D may have holes bounded by surfaces $S_1, S_2, \cdots$. The membrane is fixed on the outer boundary and free on the inner boundaries. The following two theorems are proved. Theorem A: Among all three-dimensional domains with given volume V and area S of the outer surface (the outer surface being convex) the spherically symmetric one bounded by two concentric spherical surfaces has the highest fundamental frequency. Theorem B: With the same assumptions as in Theorem A, $\lambda \leq (\pi S/2V)^2$. A two-dimensional analogue of (A) was given by the reviewer and Weinberger [J. Math. Anal. Appl. **2** (1961), 210–216; MR **26** #7220] while the two-dimensional analogue of (B) was an extension by Pólya [J. Indian Math. Soc. (N.S.) **24** (1960), 413–419; MR **24** #A2895] of earlier results of the author [Acta Sci. Math. (Szeged) **20** (1959), 33–35; MR **21** #3965].

The author shows that the convexity of S is necessary in (A) and (B). He also shows that the theorem of Pólya for a membrane fixed along its entire boundary cannot be extended to general multiply connected domains.

L. E. Payne (College Park, Md.)

Vichik, M. I. [Višik, M. I.] 4994

Sur les problèmes aux limites pour des équations quasi-linéaires elliptiques et paraboliques d'ordre supérieur.

Les Équations aux Dérivées Partielles (*Paris*, 1962), *pp.* 213–218. *Éditions du Centre National de la Recherche Scientifique*, *Paris*, 1963.

L'auteur trouve des solutions des équations quasi-linéaires elliptiques d'ordre $2m$ de forme de divergence, dans les espaces $W_p^{(m)}$ et les solutions des équations quasi-linéaires paraboliques dans des espaces $\mathscr{L}_p(0, T; W_p^{(m)})$. Il construit d'abord ces solutions en supposant que les paramètres du problème sont suffisamment réguliers, à l'aide de la méthode de Galerkine. Ensuite, par un théorème de densité, il démontre l'existence d'une solution sous des restrictions faibles sur les données du problème.

Equazioni paraboliche in due variabili. I.

Rend. Sem. Fac. Sci. Univ. Cagliari **31** (1961), 48–79.

The author considers the parabolic equation

$$\begin{aligned} L(x, y, D_x, D_y)u &= L'(x, y, D_x, D_y)u + L''(x, y, D_x, D_y)u \\ &= \sum_{j=0}^{n} (-1)^{p(n-j)} a_{n-j}(x, y) D_x^{2p(n-j)} D_y^{j} u \\ &\quad + \sum_{0 \leq i + 2pj < 2pn} b_{ij}(x, y) D_x^{i} D_y^{j} u = 0 \end{aligned}$$

on a region that can be a half-plane, a quarter-plane, a half-strip, or a rectangle. The initial and boundary conditions are the apparent ones. First he constructs a fundamental solution for $L'u = 0$ for the case of constant coefficients. He then proves uniqueness for $Lu = 0$ if the coefficients depend on x only for the half-strip. Uniqueness theorems for the quarter-plane and the rectangle are given for constant coefficients. He obtains the solution in closed form for the Cauchy problem and for initial-boundary problems for the other regions for the constant-coefficient case.

★Parabolic systems [Параболические системы].

Izdat. "Nauka", Moscow, 1964. 443 *pp.* 1.14 *r.*

The author is concerned with the following topics: fundamental solutions (f.s.), differentiability of solutions, the Cauchy problem and the initial-boundary-value problem; f.s. are first constructed and then employed in a systematic manner throughout the book.

In Chapter 1, f.s. are constructed for general parabolic systems, also in the case of unbounded coefficients, and bounds on their derivatives are obtained. It is shown that the f.s. are analytic functions in the space variable if the same is true of the coefficients. The behavior of solutions near an isolated singularity is studied.

Chapter 2 deals with interior estimates of solutions, and with their smoothness and analyticity properties. Liouville-type theorems are proved.

In Chapter 3, the Cauchy problem is solved with the aid of f.s. Existence and uniqueness theorems are proved for solutions $u(x, t)$ satisfying certain growth conditions in x; these growth conditions are sharp. Next, the Cauchy

problem is considered for perturbed non-linear equations. Finally, the behavior of the solution as $t \to \infty$ is investigated.

In Chapter 4, the initial-boundary-value problems are solved, first in a half-space for equations with constant coefficients and then in arbitrary cylinders and for equations with variable coefficients. The treatment is analogous to that of Agmon [Comm. Pure Appl. Math. **10** (1957), 179–239; MR **21** #5057] for elliptic equations, and it is an original contribution of the book.

A. Friedman (Evanston, Ill.)

Fife, Paul 4999

Solutions of parabolic boundary problems existing for all time.

Arch. Rational Mech. Anal. **16** (1964), 155–186.

The author gives conditions under which there exists a unique solution of a second-order parabolic equation in the cylinder $Q\{\Omega, -\infty < t < \infty\}$ which vanishes on the lateral surface of the cylinder; here Ω is a domain in the space $(x_1, \cdots, x_n)$. The problem studied is that of the behaviour of the solutions as $t \to \infty$. The author finds conditions under which there exists a periodic solution in Q which vanishes on the lateral surface of Q. The corresponding theorems are obtained as a consequence of certain theorems for operator equations in Banach spaces. By choosing various norms (L_2, L_1, and the maximum norm), the author obtains existence theorems for the boundary-value problem in Q in the various spaces and a priori bounds for these solutions in the corresponding norms. Analogous results are also obtained for certain classes of quasi-linear parabolic equations.

O. A. Oleinik (Moscow)

Jiang, Li-shang [Chiang, Li-shang] 5000

The proper posing of free boundary problems for non-linear parabolic differential equations.

Acta Math. Sinica **12** (1962), 369–388 (*Chinese*); *translated as Chinese Math.* **3** (1963), 399–418.

The author establishes existence and uniqueness for the free boundary problems

$$(1)\quad \partial(k(x,t,u)\partial u/\partial x)/\partial x = \partial u/\partial t \qquad (0 < x < h(t),\ t > 0);$$

$$(2)\quad -k(0,t,u(0,t))\partial u(0,t)/\partial x = g(t) \qquad (t > 0,\ g \geq 0);$$

$$(3)\quad u(h(t),t) = 0 \qquad (t > 0);$$

$$(4)\quad -k(h(t),t,0)\partial u(h(t),t)/\partial x = dh(t)/dt \qquad (t > 0);$$

$$(5)\quad h(0) = 0.$$

The proof consists of two parts: (a) establishing existence and uniqueness for (1)–(3) for any given $h(t)$ satisfying $h(t) \geq 0$, $dh(t)/dt \geq 0$, $h(0) = 0$; (b) rewriting (1)–(5) in the form $h = Th$ (the definition of T employs (a)), and proving that T has a unique fixed point. The present problem was treated by the same method by Kyner [J. Math. Mech. **8** (1959), 483–498; MR **26** #1630], but the latter author did not give a proof of (a). The present proof of (a) involves derivations of a priori bounds on the derivatives of the solution (by the method of S. N. Bernstein).

Teut, O. M. 500[5]

A boundary-value problem for a system of partial dif[-] ferential equations of mixed type. (Russian)

Boundary-value problems in the theory of functions of [a] complex variable, pp. 40–58. *Izdat. Kazan. Univ. Kazan*, 1962.

The traditional method of solving the Tricomi problem for equations of changing type is by the use of integra[l] equations for the unknown function value assume[d] between the domains of ellipticity and hyperbolicity an[d] the uniqueness of the solution to the main problem, t[o] determine the existence of this function [L. Bers, *Mathe[-] matical aspects of subsonic and transonic gas dynamics* p. 97, Wiley, New York, 1958; MR **20** #2960].

In this paper, the author discusses the system of equations of mixed type

$$(1)\quad \begin{aligned} u_x - v_y &= a_1(x, y)u + b_1(x, y)v + f_1(x, y), \\ u_y + (\operatorname{sign} y)v_x &= a_2(x, y)u + b_2(x, y)v + f_2(x, y) \end{aligned}$$

in a domain D bounded in the upper half-plane by a smooth curve σ joining $A = (-1, 0)$ to $B = (1, 0)$ and in the lower half-plane by the segments of the characteristics $AC: y = -x-1$, $-1 \leq x \leq 0$, and $BC: y = x-1$, $0 \leq x \leq 1$; a_i, b_i, f_i, $i = 1, 2$, are Hölder-continuous in the closure $\bar{D}$ of D for $y \geq 0$ and are continuously differentiable in $\bar{D}$ for $y \leq 0$. A pair of functions u, v is sought, satisfying (1) in D, such that

$$\text{(a)}\quad (u+v)|_\sigma = \gamma(t),$$

$$\text{(b)}\quad (u+v)|_{AC} = \psi(2x+1), \qquad -1 \leq x \leq 0,$$

for given functions γ, ψ, which are, respectively, Hölder-continuous on σ and twice continuously differentiable on $-1 \leq x \leq 1$; t is the complex coordinate on σ. Moreover, u, v are to be continuous on D, and have continuous derivatives throughout D except on the arc $-1 \leq x \leq 1$, where they experience jump discontinuities.

Under the additional conditions that along σ, $dx/ds \leq 0$, with s the variable of arc length (which is met for a semi-circle) and that $a_1 < 0$, and $(a_2 - b_1)^2 + 4a_1 b_2 < 0$, uniqueness of the solution to the problem is easily proved.

Let D_1 $[D_2]$ be the portion of D for which $y \geq 0$ $[y \leq 0]$. The author now obtains for a general function $\tau(x) = u(x, 0) + v(x, 0)$ a solution to the equations subject to condition (b) for the equations in D_2, the region of hyperbolicity, by transformation to characteristic co-ordinates. Under resulting conditions on the segment $-1 \leq x \leq 1$, and in the case when σ is the unit semi-circle, the equation (1) is rewritten in the complex form

$$w_{\bar{z}} + A(z)w + B(z)\bar{w} = F(z)$$

and solved explicitly in D_1 for $w = u + iv$ in terms of singular integrals depending on τ and on the coefficients of the equation. The author then obtains necessary differentiability theorems for w and is able thereby to derive integral equations for $u(x, 0)$, $v(x, 0)$ for which existence of a solution is equivalent to existence of a solution to the original problem, and for which the Fredholm alternative is applicable. By the uniqueness of the solution to the main problem, the proof is complete.

Žegalov, V. I. 5006

Some problems for the equation

$$\left(\frac{\partial^2}{\partial x^2} + \operatorname{sgn} y \frac{\partial^2}{\partial y^2}\right)^n u = 0.$$

(Russian)

Boundary-value problems in the theory of functions of a complex variable, pp. 3–16. *Izdat. Kazan. Univ., Kazan*, 1962.

The author has previously considered a generalization of the Tricomi problem, here called Problem T^n, in which the differential equation to be solved is

$$(\partial^2/\partial x^2 + \operatorname{sgn} y \partial^2/\partial y^2)^n u = 0$$

[Dokl. Akad. Nauk SSSR **136** (1961), 274–276; MR **22** #8228]. It was shown that Problem T^n could be reduced to a succession of boundary-value problems of the type known as Problem T. A method was indicated for solution, but no existence proof was given. In the present paper a smoothness condition is imposed on the solutions in this succession in order to guarantee uniqueness, and the solution is constructed with the use of n-harmonic functions. The same ideas are used to treat similar generalizations of the two problems of Ju. M. Krikunov [Izv. Vysš. Učebn. Zaved. Matematika **1961**, no. 6 (25), 60–70; MR **26** #4061]. *R. N. Goss* (San Diego, Calif.)

Wiener, Klaus 5007

Über ein gemischtes Randwertproblem für die verallgemeinerte Tricomi-Gleichung.

Wiss. Z. Martin-Luther-Univ. Halle-Wittenberg Math.-Natur. Reihe **13** (1964), 55–57.

Let $u = u(x, y)$, $0 < x < \infty$, $0 < y < \infty$, satisfy the generalized Tricomi equation

$$\text{(A)}\quad u_{yy} + y^m(u_{xx} + k^2 u) = 0, \qquad m \geq 0,\ \operatorname{Im} k > 0,$$

and the boundary conditions

$$\text{(B)}\quad u = f(x), \qquad 0 < x < 1, \quad y = 0,$$

$$\text{(C)}\quad u_y = g(x), \qquad 1 < x < \infty, \quad y = 0,$$

$$\text{(D)}\quad u_x = y^{-m}h(y), \qquad x = 0, \quad 0 < y < \infty,$$

where $f(x)$, $g(x)$, and $h(y)$ are continuous in $[0, 1]$, $[1, \infty)$, and $[0, \infty)$, respectively, and $g(x)$ and $h(y)$ are exponentially small at infinity. This mixed boundary-value problem is transformed to a Fredholm integral equation of the first kind for $u_y(x, y)$ in $x = (0, 1)$. This integral equation must be solved approximately, after which the specification of u_y on $y = 0$, $x = (0, \infty)$ permits the invocation of a known, general solution of (A). *J. W. Miles* (Canberra)

Prouse, Giovanni 5008

Soluzioni quasi-periodiche dell'equazione differenziale di Navier-Stokes in due dimensioni.

Rend. Sem. Mat. Univ. Padova **33** (1963), 186–212.

This paper treats the existence, uniqueness, and almost periodicity of bounded weak solutions $x(\xi_1, \xi_2, t)$ of the 2-dimensional Navier-Stokes system in $\Omega \times (-\infty, \infty)$, where Ω is an open set in the (ξ_1, ξ_2)-plane. Let N and N^1 be the closures with respect to the norms $\|u\|_{L^2} = (\int_\Omega |u|^2 d\Omega)^{1/2}$ and $\|u\|_{H_0^1} = (\int_\Omega |\nabla u|^2 d\Omega)^{1/2}$, respectively, of smooth divergence-free vector functions vanishing near $\partial\Omega$. Consider functions $v(t)$ from $(-\infty, \infty)$ to $L^2(\Omega)$ such that for each t, the norm

$$\|v(t)\|_{L_0^2(L^2)} = \left(\int_{-1}^0 \|u(t+\eta)\|_{L^2}^2 \, d\eta\right)^{1/2}$$

exists; then the range of v can be interpreted as lying in $L_0^2(L^2) = L^2(-1, 0; L^2(\Omega))$. One defines $v(t) \in L_0^2(H_0^1)$, $L_0^2(N^1)$, $L_0^\infty(N)$ similarly. By a weak solution of the Navier-Stokes system with homogeneous Dirichlet data, the author means a function $x(t) \in L_0^2(N^1) \cap L_0^\infty(N)$ satisfying

$$\int_{-\infty}^{\infty} \{(x(t), h(t))_{H_0^1} - (x(t), h'(t))_{L^2} + b(x(t), x(t), h(t))\}\, dt = \int_{-\infty}^{\infty} (f(t), h(t))_{L^2}\, dt$$

for every $h(t)$ of compact support which is N^1-continuous in t with $h'(t) \in L_0{}^2(N)$. (Here $b(u, v, w) = \int_\Omega \sum u_i (\partial v_j/\partial \xi_i w_j)\, d\Omega$.) The inhomogeneous term $f(t)$ is supposed to have its range in $L_0{}^1(L^2)$.

The author proves the following. (1) If $f(t)$ is L^2-bounded uniformly in t, there exists a weak solution defined for all time which is also L^2-bounded in $(-\infty, \infty)$. (2) If f is "small enough" (or, more generally, if there exists a solution that is small enough), then uniqueness holds among functions L^2-bounded in $(-\infty, \infty)$. (3) If $f(t)$ is weakly almost periodic with respect to the norm of $L_0{}^2(L^2)$ (abbreviated $L_0{}^2(L^2)$-w.a.p.) then the solution $x(t)$ is L^2-w.a.p. and $L_0{}^2(L^2)$-almost periodic ($L_0{}^2(L^2)$-a.p.). (4) If $f(t)$ is $L_0{}^2(L^2)$-a.p. and $x(t)$ is small enough, then $x(t)$ is L^2-a.p. and $L_0{}^2(H_0{}^1)$-a.p.

The results of Amerio [Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **31** (1961), 110–117; MR **25** #3389; ibid. (8) **31** (1961), 197–205; MR **26** #2879; Ricerche Mat. **9** (1960), 255–274; MR **24** #A896] on almost periodic solutions of equations in Hilbert spaces are used extensively. *P. C. On the sums $\sum_{k=0}^{n} k^p$ and $\sum_{k=0}^{n} (-1)^k k^p$.

Proc. Amer. Math. Soc. **15** (1964), 642–647.

Let u_k satisfy the linear difference equation of order m with real constant coefficients

$$u_{m+k} + a_1 u_{m+k-1} + \cdots + a_m u_k = 0, \qquad k = 0, 1, 2, \cdots.$$

The author derives a closed form for $\sum_{k=0}^{\infty} u_k r^k$, and thus closed forms for the sums given in the title, as well as certain other formulae.

L. M. Milne-Thomson (Tucson, Ariz.)

Koroljuk, V. S. 5011

The asymptotic behavior of solutions of difference equations with small parameters. (Russian)

Ukrain. Mat. Ž. **12** (1960), 342–346.

In analogy with a method used for differential equations by M. I. Višik and L. A. Ljusternik [Uspehi Mat. Nauk **12** (1957), no. 5 (77), 3–122; MR **20** #2539], a process is set up for obtaining an asymptotic expression (for small ε) for solutions of difference equations of the form (1) $P_\varepsilon u_\varepsilon(x) \equiv \sum_{k=-\infty}^{+\infty} p_k u_\varepsilon(x+k\varepsilon) = 0$ (x/ε an integer), with $u_\varepsilon(x)$ given for $x \leq 0$ and $x \geq 1$. Four conditions are assumed. (a) The coefficients p_k in (1) depend on ε in such a way that $\sum_{k=-\infty}^{+\infty} |k|^{N+1} |p_k| \leq C$ (independent of ε) for some positive integer N, and ε sufficiently small. (b) Let $\rho_m = (1/m!) \sum_{k=-\infty}^{+\infty} k^m p_k$ $(m = 0, \cdots, N)$. Then asymptotically $(\varepsilon \to 0)$, $\rho_m = \varepsilon^{n-m} \sum_{r=0}^{N+1} \varepsilon^r a_{mr}$ $(m = 0, \cdots, n)$, $\rho_{n+l} = \sum_{r=0}^{N+1-n-l} \varepsilon^r a_{n+l,r}$ $(l = 1, \cdots, N-n)$, with $a_{n0} \neq 0$. Here n is the order of the differential operator $L_0 = \sum_{m=0}^{n} a_{m0} d^m/dx^m$ to which P_ε of (1) passes for $\varepsilon \to 0$. (c) Let $p_0(\lambda) = \sum_{k=-\infty}^{+\infty} p_{k0} \lambda^k$, where $p_k = p_{k0} + O(\varepsilon)$, p_{k0} independent of ε. Then $n_0, n_1 > 0$ exist $(n_0 + n_1 = n)$ such that $q(\lambda) = p_0(\lambda)(\lambda - 1)^{-n_1}(1 - \lambda^{-1})^{-n_0} \neq 0$ on the circle $|\lambda| = 1$, and $\operatorname{index}_{|\lambda|=1} q(\lambda) = 0$. (d) The non-homogeneous equation $\varepsilon^{-n} P_\varepsilon u_\varepsilon = g$, with bounded exterior conditions (i.e., for $x \leq 0$, $x \geq 1$) for $\varepsilon \to 0$, is uniformly solvable in the sense that for ε sufficiently small, $\|u_\varepsilon\| \leq K\|g\|$ (K independent of ε).

The actual asymptotic expression obtained for $u_\varepsilon(x)$ involves too much detail to present here. The author notes that his method can be extended to the case in which the coefficients p_k involve x as well as ε.

Newns, W. F. 5012

On the difference and sum of a basic set of polynomials.

Pacific J. Math. **14** (1964), 639–644.

The reader is expected to be familiar with terminology and fundamental results on basic sets of polynomials, as contained in J. M. Whittaker's book, *Sur les séries de base de polynômes quelconques* [Gauthier-Villars, Paris, 1949; MR **11**, 344]. The author proves two theorems on best possible bounds for the orders of the difference set and the sum set of a basic set, as established in N. N. Mikhail and M. Nassif [Pacific J. Math. 11 (1961), 1099–1107; MR **25** #347]. By considering spaces of integral functions, he extends one of the theorems to integral functions, and he obtains related results which he believes provide a deeper insight into the problem. He notes that either approach can be used to determine the types of the sets, as well as their orders. *R. A. Rosenbaum* (Middletown, Conn.)

Choczewski, B.; Kuczma, M. 5013

Sur certaines équations fonctionnelles considérées par I. Stamate.

Mathematica (Cluj) **4** (**27**) (1962), 225–233.

The authors consider the following functional equation

$$(1) \quad \frac{xf(y) - yf(x)}{x - y} = F[u, f(u), f'(u), \cdots, f^{(n)}(u); g(u), g'(u), \cdots, g^{(m)}(u)],$$

where F and $u = u(x, y)$ are given functions and f is a function to be determined. This equation is a generalisation of some equations considered by I. Stamate [Inst. Politehn. Lucrăr. Şti. **1959**, 107–110; MR **22** #A2654]. If $u(x, y) = (x+y)/2$, then f is linear, i.e., $f(x) = a + bx$. However, if u has a more general structure, then some additional assumptions are to be made. Under suitable conditions the authors find that f has the form

$$(2) \qquad f(x) = a_0 + a_1(x - a) + a_2 \int \frac{a - xv(x)}{a(x-a)}\, dx,$$

where a_0, a_1, a_2 and a are constants, $0<a<1$, and $v(x)=-(\partial u(x,a)/\partial x)/(\partial u(x,a)/\partial y)$. In general, the function (2) need not satisfy the equation (1). The question, under which additional assumptions (2) satisfies (1), is discussed. A necessary but not sufficient condition is that $(xf(w)-wf(x))/(x-w)$ does not depend on x, where w is a function such that $u(x, w(x,z))\equiv z$ in some neighborhood.

Gumowski, Igor; Clergue, Michel 5014

Sur les solutions analytiques d'une équation différentielle-fonctionnelle d'ordre 1.

C. R. Acad. Sci. Paris **253** (1961), 1522–1528.

The authors claim as their principal result the theorem that the differential-difference equation (1) $\dot u(t)=-u(t-r)$ has a unique solution $u=u^*(t,r)$, analytic with respect to t and r at $(0,0)$, with prescribed initial value $u^*(0,r)=u_0$. They propose to find u^* as the limit of the sequence of successive approximations (2) $(u_n: n=0,1,\cdots)$, where $u_0(t)=u_0$ and $u_{n+1}(t)=u_0-\int_0^t u_n(s-r)\,ds$. They assert that the requisite convergence of (2) has been shown, for $0\leq r\leq 0.3$, by a computer. {Reviewer's note: An easy estimation argument shows that (2) converges (for all t) if $r<1/e$.} The authors assert also that it can be shown by a computer that (2) diverges if $r\geq 0.4$. They cite various salient parts of the literature on (1).

SEQUENCES, SERIES, SUMMABILITY

See also 5052, 5100.

Matsuyama, Noboru 5015

A note on convergence of gap series.

Sci. Rep. Kanazawa Univ. 8, 271–277 (1963).

Let $f(t)$ be an integrable function with period 1 such that the mean of f is 0 and the variance is 1. Let (n_k) be a sequence of positive integers with the Hadamard gap $n_{k+1}/n_k>c>1$ $(k=1,2,3,\cdots)$. The author proves the following three theorems. (I) If (i) $(\int_0^1 |f(t)-s_n(t;f)|^2\,dt)^{1/2}=O(1/(\log n)^\alpha)$ for $\alpha>1$, where $s_n(t:f)$ is the nth partial sum of the Fourier series of f, and if (ii) $\sum c_k^2 \log_q k<\infty$ for a q, where $\log_1 k=\log k$, $\log_{q+1} k=\log(\log_q k)$, then the series $\sum c_k f(n_k t)$ converges a.e. (II) If (i) holds for $0<\alpha<\frac12$ and $\beta>1-\alpha$ or $\frac12\leq\alpha<1$ and $\beta>\frac12$, then $\sum f(n_k t)/k^\beta$ converges a.e. (III) If (i) holds for $\alpha=1$ and $\beta>\frac12$, then $\sum f(n_k t)/\sqrt{k}(\log k)^\beta$ converges a.e.

Lorentz, G. G.; Zeller, K. 5016

Abschnittslimitierbarkeit und der Satz von Hardy-Bohr.

Arch. Math. **15** (1964), 208–213.

Given $\alpha\geq 0$, let $\mathbf{C}$ denote the Banach space of number sequences $\mathbf{a}=\{a_k\}_{k=0}^\infty$ such that $\sum a_k$ is C_α-summable, where C_α denotes the Cesàro mean of order α. Let $\{\sigma_m\}$ denote the C_α transform of the sequence of partial sums of $\sum a_k$, and take $\|\mathbf{a}\|=\sup|\sigma_m|$. For each non-negative integer k, let $\mathbf{e}_k$ denote the point of $\mathbf{C}$ whose nth coordinate is unity if $n=k$ and zero if $n\neq k$. Using the Hardy-Bohr characterization of C_α convergence factors, K. Zeller had previously shown that, for $\mathbf{a}\in\mathbf{C}$, the series $\sum a_k\mathbf{e}_k$ is C_α-summable (in the norm of $\mathbf{C}$) to $\mathbf{a}$.

In this paper the authors use techniques from functional analysis to obtain a more direct proof of this theorem. Apart from its functional-analytic content, the proof depends mainly on establishing the binomial coefficient inequality

$$\sum_{k=0}^{\min(m,n)}\binom{m-k+\alpha}{m-k}\binom{n-k+\alpha}{n-k}\binom{k-\alpha-2}{k}\geq 0,$$

where m and n are non-negative integers and $\alpha\geq 0$. The same method also yields a computationally simpler proof of the theorem of Hardy and Bohr.

Petersen, G. M.; Baker, Anne C. 5017

On a theorem of Pólya. II.

J. London Math. Soc. **39** (1964), 745–752.

This paper is the fourth in a series of papers dealing with the solution of infinite systems under certain restrictions on the coefficient matrix [see Petersen and Thompson, same J. **38** (1963), 335–340; MR **27** #3652; ibid. **39** (1964), 31–34; MR **28** #4270; Petersen and Baker, ibid. **39** (1964), 501–510; MR **29** #2280]. A matrix $\{a(i,j)\}$ which satisfies

$$\liminf_{j\to\infty}\frac{|a(1,j)|+|a(2,j)|+\cdots+|a(i-1,j)|}{|a(i,j)|}=0 \qquad (i=1,2,\cdots)$$

for all but finitely many rows, and any finite selection of rows are independent, is called a Pólya matrix. Matrices that are obtained from each other by permuting rows or by a sequence of additions of one row to another, with the restriction that no row has infinitely many others added to it, are termed equivalent. The authors prove the following. Let $A=\{a(i,j)\}$ be a matrix such that $a(1,j)\neq 0$ $(j=1,2,\cdots)$. For any selection of real numbers $\{b(i)\}$, the infinite system of equations $\sum_j a(i,j)u(j)=b(i)$ $(i=1,2,\cdots)$ has solutions $\{u(j)\}$ such that the left-hand sides converge absolutely and with any arbitrary finite subset of the $u(j)$ equal to zero if and only if A is equivalent to a Pólya matrix.

Slipenčuk, K. M. [Slepenčuk, K. M.] 5018

Some methods for summation of series. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1963**, 1559–1562.

$(W^{(\alpha)},\lambda)$ est un procédé régulier de sommation défini par $\lambda_{n+1}\geq\lambda_n$, $\lambda_0=0$, $W_n^{(\alpha)}=\lambda_n^{-1}\sum_{k=1}^n(\lambda_{n+1-k}-\lambda_{n+k})W_{k-1}^{(\alpha-1)}$, $W_n^0=S_n=\sum_0^k a_k$, $W_0^{(\alpha)}=0$. Si la série $\sum a_k$ est $(W^{(\alpha)},\lambda)$-sommable vers S, alors $\lambda_n^{-1}\sum_{k=1}^n(\lambda_n-\lambda_{n-k})a_k\to 0$, $n\to\infty$, est la condition nécessaire et suffisante pour la convergence de $\sum a_k$ vers S.

L'auteur donne aussi une condition telle que $|W^{(\alpha)},\lambda|$-sommabilité de $\sum a_k$ implique la convergence absolue de $\sum a_k$.

M. Tomić (Belgrade)

Slipenčuk, K. M. [Slepenčuk, K. M.] 5019

A theorem of Tauberian type for $(H^{(\alpha)},\lambda)$-methods of summation of double series. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 312–314.

Le procédé $(H^{(\alpha)}, \lambda)$ est défini par $\alpha = 1, 2, \cdots$; $\lambda_{k0} = \lambda_{0l} = 0$; $\lambda_{kl} \to \infty$, $k, l \to \infty$, $\lambda_{k,l+1} > \lambda_{kl}$, $\lambda_{k+1,l} > \lambda_{kl}$,

$$\lim_{k,l\to\infty} \frac{\lambda_{k_0 l}}{\lambda_{kl}} = \lim_{k,l\to\infty} \frac{\lambda_{kl_0}}{\lambda_{kl}} = 0 \qquad (k_0, l_0 \text{ fixes}).$$

La série double (*) $\sum_{k=0}^{\infty} \sum_{l=0}^{\infty} a_{kl}$ est $(H^{(\alpha)}, \lambda)$-sommable vers S si $H_{mn}{}^{\alpha} \to S$ quand $m, n \to \infty$, où

$$H_{mn}{}^{\alpha} = (\lambda_{m+1,n+1})^{-1} \sum_{k=0}^{m} \sum_{l=0}^{n} \Delta\lambda_{kl} H_{kl}{}^{(\alpha-1)},$$

$$\Delta\lambda_{kl} = \lambda_{k+1,l+1} - \lambda_{k,l+1} - \lambda_{k+1,l} + \lambda_{kl},\ H_{mn}{}^{(0)} = S_{mn}.$$

On établit la condition nécessaire et suffisante pour que la série double (*), $(H^{(\alpha)}, \lambda)$-sommable vers S, avec $|S_{kl}| < M$, converge vers la même somme. *M. Tomić* (Belgrade)

Kuttner, B. 5020

The high indices theorem for discontinuous Riesz means.

J. London Math. Soc. **39** (1964), 635–642.

If $0 < \lambda_n \nearrow \infty$ and $k > 0$, the series $\sum u_n$ is called (R, λ_n, k)-summable to s if $w^{-k}A_k(w) \to s$ $(w \to +\infty)$, where $A_k(w) = \sum_{\lambda_n < w} (w - \lambda_n)^k u_n$, and (R^*, λ_n, k)-summable if $\lambda_n{}^{-k}A_k(\lambda_n) \to s$ $(n \to \infty)$. It is well known that (R, λ_n, k)-summability implies convergence if the λ_n satisfy (1) $\liminf \lambda_{n+1}/\lambda_n > 1$, and since (R, λ_n, k) and (R^*, λ_n, k) are equivalent for $0 < k \leq 1$, (1) is a high-indices condition for (R^*, λ_n, k) $(0 < k \leq 1)$. The author shows that it is also a high-indices condition for $(R^*, \lambda_n, 2)$ and (R^*, c^n, k) if $c > 1$, $1 < k < 2$, whereas (1) is not a high-indices condition for (R^*, λ_n, k) $(k > 2)$, not even if $\lambda_n = c^n$ $(1 < c < c_0(k))$. However, the stronger condition

$$\liminf \lambda_{n+1}/\lambda_n > 2^{1/k}/(2^{1/k} - 1)$$

is always a high-indices condition for (R^*, λ_n, k) $(k > 0)$. The proofs concerning the case $\lambda_n = c^n$ depend on the lemma: If $k > 0$, $c > 1$, then (R^*, c^n, k) is equivalent to convergence if and only if

$$\Phi(z) = \sum_{n=0}^{\infty} (1 - c^{-n-1})^k z^n \neq 0 \qquad (|z| \leq 1, z \neq 1).$$

D. Gaier (Pasadena, Calif.)

Kuttner, B. 5021

A Tauberian theorem for discontinuous Riesz means. II.

J. London Math. Soc. **39** (1964), 643–648.

With the notations of #5020 above, the problem is under what conditions the following proposition (*) is true: (R^*, λ_n, k)-summability implies (R, λ_n, k)-summability. The author proved earlier [J. London Math. Soc. **38** (1963), 189–196; MR **26** #6649] that (*) is true if (1) $\Lambda_{n-1} = O(\Lambda_n)$, where $\Lambda_n = \lambda_{n+1}/(\lambda_{n+1} - \lambda_n)$, and (2) $u_n = o(\Lambda_n{}^k)$, provided $k > 0$ is an integer. This result is now extended to non-integer values of k if additional conditions are imposed on the λ_n; for example,

$$(3) \quad \sum_{\nu=0}^{n} \lambda_\nu{}^{q+1}(\lambda_{\nu+1} - \lambda_\nu)^{k-q-1}\Lambda_\nu{}^k = O(\lambda_{n+1}^k \Lambda_{n+1}^{q+1})$$

(some integer q)

is [together with (1) and (2)] sufficient to imply (*). Condition (3) holds if $\{\lambda_n\}$ is a logarithmico-exponential sequence. It is also proved that (R, λ_n, k) and (R^*, λ_n, k) are not equivalent for $k > 1$, a result that had been known only for $k \geq 2$. *D. Gaier* (Pasadena, Calif.)

Levinson, Norman 5022

Absolute convergence and the general high indices theorem.

Duke Math. J. **31** (1964), 241–245.

For Dirichlet series $f(x) = \sum_1^{\infty} a_n e^{-\lambda_n x}$, where the λ_n satisfy a gap condition $\lambda_{n+1}/\lambda_n \geq q^2 > 1$ $(\lambda_1 > 0)$, Zygmund proved the following relation between the l^1 norm of the coefficient sequence a and the L^1 norm of f' on $(0, \infty)$: $\|a\| \leq A_q \|f'\|$, where A_q depends only on q [Trans. Amer. Math. Soc. **55** (1944), 170–204; MR **5**, 230]. The author extends Zygmund's result to kernels $N(x)$ much more general than the power series kernel e^{-x}. Most of the conditions imposed on $N(x)$ are formulated in terms of the Fourier transform $k(w) = \int_0^{\infty} N'(x)x^{-iw}dx$. They are too numerous to be stated in a review, and are very similar to the conditions in the author's general high-indices theorem [*Gap and density theorems*, Theorem LI, Amer. Math. Soc., New York, 1940; MR **2**, 180]. The conditions on $N(x)$ are, in particular, satisfied for the Lambert series kernel $xe^{-x}/(1 - e^{-x})$. *J. Korevaar* (La Jolla, Calif.)

Pleijel, Åke 5023

On a theorem by P. Malliavin.

Israel J. Math. **1** (1963), 166–168.

The author gives a simple proof, with a slightly better remainder, of a Tauberian theorem of Malliavin [C. R. Acad. Sci. Paris **255** (1962), 2351–2352; MR **26** #1662]. Let $f(z) = \int_0^{\infty} (\lambda - z)^{-1} d\sigma(\lambda)$, with $d\sigma \geq 0$, and let L be a contour consisting of the arcs $y = \pm x^{\gamma}$, $1 \leq x < \infty$, where $0 \leq \gamma < 1$, and a connecting arc which does not meet the half-line $y = 0$, $x \geq 0$. It is assumed that $f(z) = a(-z)^{\alpha} + O(z^{\beta})$ as $z \to \infty$ along L; here $-1 < \alpha < 0$ and $\beta < \alpha$. The author denotes by $L(Z)$ the part of L from $\bar{Z}$ to $Z = X + iY$ $(X > 1)$. He observes that

$$\frac{1}{2\pi i} \int_{L(Z)} f(z)\, dz = \sigma(X) - \sigma(0) + O(X^{\alpha+\gamma}),$$

and uses this result to show that $\sigma(X) - \sigma(0) = aC(\alpha)X^{\alpha+1} + O(X^{\alpha+\gamma}) + O(X^{\beta+1}) + A$. The constant A is present only when $\beta < -1$, and the term $O(X^{\beta+1})$ has to be replaced by $O(\log X)$ when $\beta = -1$. *J. Korevaar* (La Jolla, Calif.)

Skof, Fulvia 5024

Sull'attenuazione delle condizioni tauberiane.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 466–468.

Let (C) denote the class of power series $\sum a_n z^n = f(z)$ which converge for $|z| < 1$ and are such that $\lim_{r\to 1-} f(re^{i\theta}) = g(\theta)$ exists uniformly in θ $(0 \leq \theta < 2\pi)$. The author announces, without proofs, three theorems, the simplest of which is Theorem A. Let two strictly positive functions $\varepsilon(t)$ and $\psi(t)$ be given. Assume that $\varepsilon(t) \to 0$, $\psi(t)$ increases to $+\infty$, $\psi(t)/t$ decreases to 0. Then, there exists some $f(z) \in$ (C) with the following two properties. (i) $|a_n| \leq \psi(n)/n$, (ii) there are arbitrarily large n for which $|a_n| = \psi(n)/n$ and $|a_0 + a_1 \cdots + a_n| > \varepsilon(n) \log \psi(n)$.

As is pointed out by the author, this result (which sharpens an analogous theorem of Turán) is connected with Littlewood's Tauberian theorem and a result of Titchmarsh.

The two other results stated by the author have the same general character as Theorem A and are connected with a one-sided Tauberian condition studied by R. Schmidt and T. Vijayaraghavan.

A. Edrei (Syracuse, N.Y.)

Subhankulov, M. A. 5025

On a theorem of Littlewood. (Russian. Uzbek summary)

Izv. Akad. Nauk UzSSR Ser. Fiz.-Mat. Nauk **1964**, *no.* 1, 22–30.

The author proves two Tauberian remainder theorems related to the following result of Littlewood. Let $F(\sigma)$, $\sigma>0$, be the sum of an absolutely convergent Dirichlet series $\sum_{n=0}^{\infty} a_n e^{-\lambda_n \sigma}$, where $\lambda_n \uparrow \infty$. Suppose that $F(\sigma)\to l$ as $\sigma \downarrow 0$, that $a_n=O\{(\lambda_n-\lambda_{n-1})/\lambda_n\}$, and that $\lambda_{n+1}\sim\lambda_n$. Then $\sum_{n=0}^{\infty} a_n=l$. Since the conditions in the general remainder theorems are very complicated, only some of the corollaries for power series will be quoted here. Let $f(z)=\sum_{n=0}^{\infty} a_n z^n$, where $z=re^{i\theta}$ and $a_n=O(n^{-\nu})$ with $0<\nu\leq 1$. (1) Suppose that in a region G bounded by curves of the form $|\theta|=c(1-r)^{\omega}$, $0<\omega<\nu$, and $r=e^{-c}$, one has an estimate $f(z)=l+O(|1-z|^{\alpha})$, $\alpha>0$. Then $\sum_{n\leq x} a_n=l+O(x^{-\alpha\omega})+O(x^{\omega-\nu})$. (2) If $f(z)$ is regular at the point $z=1$, then $\sum_{n\leq x} a_n=f(1)+O(x^{-\nu})$.

The author credits the second result to Fatou and the reviewer. Actually, the reviewer obtained a more general result corresponding to a one-sided Tauberian condition [Nederl. Akad. Wetensch. Proc. Ser. A **57** (1954), 46–56; MR **15**, 698]. In a third and older type of result, due to Freud [Acta Math. Acad. Sci. Hungar. **2** (1951), 299–308; MR **14**, 361, and subsequent papers] and the reviewer [Duke Math. J. **18** (1951), 723–734; MR **13**, 227, and subsequent papers], there is only a hypothesis on $f(x)-l$ for real x; in this case, the remainder estimates are usually rather weak. The first type of result of the author provides a significant intermediate form between the older second and third type of remainder theorems.

Džrbašjan, M. M.; Kitbaljan, A. A. 5028

On a generalization of the Chebyshev polynomials. (Russian. Armenian summary)

Akad. Nauk Armjan. SSR Dokl. **38** (1964), 263–270.

Avec un continuum borné K dans le plan et une suite de nombres complexes $z_0, z_1, \cdots$ situés dans le domaine contigu à K qui contient le point à l'infini, Džrbašjan avait associé dans deux travaux antérieurs [Izv. Akad. Nauk Armjan. SSR Ser. Fiz.-Mat. Nauk **10** (1957), no. 1, 21–29; MR **20** #3297; Dokl. Akad. Nauk SSSR **143** (1962), 17–20; MR **25** #207] un système $\{M_k^{(s)}(z)\}_{k=0}^{\infty}$ de fonctions rationnelles dépendant d'un paramètre s, $0\leq s\leq 1$. Dans le travail présent on considère un cas particulier, celui où K coïncide avec le segment $[-1,1]$ et $s=0$ ou 1. On démontre que la suite $\{M_k^{(0)}(z)\}_{k=0}^{\infty}$ est orthogonale sur $[-1,1]$ avec le poids $1/\sqrt{(1-x^2)}$, et la suite $\{M_k^{(1)}(z)\}_{k=0}^{\infty}$ également. mais avec le poids $\sqrt{(1-x^2)}$.

E. J. Akutowicz (Bologna)

Rusak, V. N. 5029

On approximations by rational fractions. (Russian)

Dokl. Akad. Nauk BSSR **8** (1964), 432–435.

Soit $\beta_k=r_k e^{i\vartheta_k}$ une suite donnée de nombres complexes telle que $r_k<1$ et $\sum(1-r_k)=+\infty$. La fonction

$$K_n(t,x) = \sin\left\{\int_x^t \left(\frac{1}{2}+\sum_{k=1}^{n}\frac{1-r_k^2}{1+r_k^2-2r_k\cos(u-\vartheta_k)}\right)du\right\}$$

généralise le noyau sommatoire de Dirichlet, qui en résulte lorsque $\beta_k\equiv 0$. Posons, après Fejér, pour une fonction f de période 2π:

$$(1)\qquad \Phi_n(f;t) = \frac{\int_{-\pi}^{\pi} f(x)[K_n(t,x)]^2\,dx}{\int_{-\pi}^{\pi} K_n(t,x)^2\,dx}.$$

En désignant par $\gamma_n(t)$ le dénominateur précédent, l'auteur énonce le résultat suivant. Si la fonction $f(t)$ appartient à la classe Lip α, $0<\alpha<1$, alors

$$|\Phi_n(f;t)-f(t)| \leq \left(1+\frac{2\pi^2}{1-\alpha}\right)\gamma_n(t)^{-\alpha}.$$

En remplaçant les exposants 2 dans (1) par 4, après Jackson, on obtient un noyau $D_n(f;t)$ pour lequel

$$|D_n(f;t)-f(t)| \leq \text{const}\cdot\omega(1/\gamma_n(t)),$$

avec une constante indépendante de n, t; ω désigne ici le module de continuité de la fonction $f(t)$.

Aramă, O.; Ripianu, D. 5030

Sur la monotonie de la suite des dérivées des polynomes de Bernstein.

Mathematica (Cluj) **4** (27) (1962), 9–19.

Let $f(x)$ be real analytic on $[0, 1]$ with the additional property that all derivatives of order $\geqq 2$ are non-negative on $[0, 1]$. Let $B_n(x; f)$ denote the nth Bernstein polynomial of $f(x)$. The authors show the existence of a subinterval $[0, \lambda]$, independent of $f(x)$, such that the sequence $\{B_n(x; f)\}_{n \geqq 1}$ is non-decreasing for each x of the subinterval. The case $f(x) = x^2$ shows that λ cannot exceed $\frac{1}{2}$. The authors give reasons for believing that $\frac{1}{2}$ is an admissible value of λ, but are unable to prove that it is.

D. S. Greenstein (Evanston, Ill.)

Boehm, Barry 5031

Functions whose best rational Chebyshev approximations are polynomials.

Numer. Math. **6** (1964), 235–242.

Tschebyscheff-Approximation stetiger Funktionen auf einem reellen kompakten Intervall tritt die Frage nach dem günstigsten Verhältnis vom Zähler- zum Nennergrad der rationalen Funktion auf. In der vorliegenden Arbeit, einem Auszug aus der Dissertation des Verfassers, wird ein Teil dieser Frage geklärt: Es wird untersucht, wann die beste rationale Approximation ein Polynom darstellt. In einigen Fällen gelingt eine vollständige Charakterisierung solcher Funktionenklassen, und es ergeben sich Sätze von der folgenden Art: Die beste rationale Approximation vom Zähler- und Nennerhöchstgrad n ist für alle n genau dann ein Polynom, wenn $f(x)$ die Form $f(x) = c + dT_m(x)$ mit einem Tschebyscheffschen Polynom von geeignetem Grad m besitzt.

Bei allgemeinem Gradverhältnis wird durch spezielle Tschebyscheff-Entwicklungen die Existenz von Funktionen $f(x)$ mit der obigen Eigenschaft nachgewiesen.

Briones, F. 5032

On the alternants appearing in Chebyshev's best approximation problem.

Numer. Math. **6** (1964), 211–223.

Eine auf einem reellen kompakten Intervall B reellwertige und stetige Funktion $A_N(x)$ heiße eine Alternante der Ordnung N, wenn es $N+1$ der Größe nach geordnete Punkte x_i aus B gibt, so daß

$$A_N(x_i) + A_N(x_{i+1}) = 0 \text{ und } |A_N(x_i)| = \max_{x \in B} |A_N(x)| = E_N \quad \text{für } i = 1, 2, \cdots, N$$

gilt. Derartige Alternanten treten bekanntlich als Fehlerfunktionen bei Tschebyscheffschen Approximationen auf. Ausgehend von einer komplexen Darstellung $A_N(x) = \mathrm{Re}\{E_N \cdot e^{it(x)}\}$ mit einer reellen Phasenfunktion $t(x)$ werden Alternanten der Ordnung K in der Form

$$A_K(x) = \mathrm{Re}\{(E_N)^{K/N} \cdot e^{i(K/N)t(x)}\}$$

gewonnen. Sie genügen ähnlichen Rekursionsformeln wie die Tschebyscheffschen Polynome. Mit Hilfe der so konstruierten Alternantenfamilien können Tschebyscheffsche Approximationsaufgaben angenähert gelöst werden. Dies wird an einigen Beispielen theoretischer und numerischer Art illustriert. Die gewonnene Annäherung kann durch eine iterative Methode verbessert werden. Spezielle Untersuchungen beziehen sich auf Funktionen, die durch eine Tschebyscheff-Entwicklung, allgemeiner durch eine Entwicklung nach einer orthogonalen Alternantenfamilie gegeben sind, auf Approximationen mit rationalem Gewicht und auf Approximationen mit kleinstem relativen Fehler.

Brown, A. L. 5033

Best n-dimensional approximation to sets of functions.

Proc. London Math. Soc. (3) **14** (1964), 577–594.

Let E be a subset of the normed linear space B, and for a given n-dimensional subspace L_n of B define $\delta(E, L_n) = \sup\{d(x, L_n) : x \in E\}$. Let $r_n(E) = \inf\{\delta(E, L_n) : L_n \subset B\}$. If $r_n(E) = \delta(E, L_n)$ for some n-dimensional L_n, then the latter is said to be an extremal subspace for E. The author is concerned with the existence of extremal subspaces for subsets of $C(S)$, the space of real-valued continuous functions on the compact Hausdorff space S. Theorem 8 asserts that every finite subset of $C(S)$ has an extremal n-dimensional subspace. Theorem 11 shows that for each $n \geqq 1$ there is an $(n+3)$-dimensional subset of $C(S)$ which has no extremal n-dimensional subspace, provided S satisfies a certain connectedness property. (This should be contrasted with the result of Garkavi [Izv. Akad. Nauk SSSR Ser. Mat. **26** (1962), 87–106; MR **25** #429] that in any Banach space every $(n+1)$-dimensional set has an extremal n-dimensional subspace.) Theorem 12, which is a corollary to the proof of Theorem 11, shows that for each $n \geqq 1$ there exists a continuous function of the form $\sum_{i=1}^{n+3} \varphi_i(s)\psi_i(t)$ on the unit square which has no best uniform approximation by a continuous function of the form $\sum_{i=1}^{n} f_i(s)g_i(t)$. These and other related results are for the most part proved by quite geometrical methods.

The exact constant of approximation of continuous functions by the Jackson singular integral.

Acta Math. Sinica **14** (1964), 231–237 (*Chinese*); *translated as Chinese Math.* **5** (1964), 254–260.

Let $J_n(f)$ denote the Jackson integral of the function f; the usual notation is so changed that $J_n(f)$ becomes a trigonometric polynomial of degree n. The author shows that the smallest constant C for which $\|f - J_n(f)\| \leq$

$C\omega(f; 1/(n+1))$ holds for all $n=0, 1, \cdots$ and all continuous functions f is $C=\frac{3}{2}$. He treats similarly another singular integral.

{Reviewer's remark: A first result in this direction is due to P. C. Sikkema [Numer. Math. **3** (1961), 107–116; MR **23** #A459]. He shows that for the Bernstein polynomial $B_n(f)$, the smallest C for which $\|f-B_n(f)\| \leq C\omega(f; n^{-1})$ for all $n=1, 2, \cdots$ and all continuous f on $[0, 1]$ is $C=(4306+837\sqrt{6})/5832$. This value is attained only for $n=6$.} *G. G. Lorentz* (Syracuse, N.Y.)

Wilf, Herbert S. 5036

The stability of smoothing by least squares.

Proc. Amer. Math. Soc. **15** (1964), 933–937.

The author uses the definition of stability for a smoothing process given by I. J. Schoenberg [Bull. Amer. Math. Soc. **59** (1953), 199–230; MR **15**, 16]. This definition is not explicitly stated in this paper. Necessary and sufficient conditions for the stability of a discrete polynomial smoothing process are known. The result of this paper may be formulated as follows. Consider the continuous least squares polynomial smoothing process: $f(x)$ is given on $[-\infty, +\infty]$, $P_x(t)$ is the polynomial of degree k or less such that $\int_{x-1}^{x+1} [f(t)-P_x(t)]^2 dt$ is minimized for all such polynomials. The smoothed value of $f(x)$ is $P_x(x)$. The following theorem is established by a detailed examination of certain definite integrals of Bessel functions. There exists K_0 such that for $k \geq K_0$, the continuous least squares polynomial smoothing process is stable. It is not known whether $K_0=0$ or not.

J. R. Rice (W. Lafayette, Ind.)

Natanson, I. P. 5037

Saturation classes in the theory of singular integrals. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 520–523.

L'auteur considère un processus d'approximation d'une fonction $f(x)$ continue et de période 2π ($f \in C_{2\pi}$) par des intégrales singulières,

$$(1) \qquad U_n(f; x) = \int_{-\pi}^{\pi} f(t)\Phi_n(t-x)\,dt,$$

où le noyau $\Phi_n(t)$ est continu, pair, positif, de période 2π et satisfait aux conditions

$$\int_{-\pi}^{\pi} \Phi_n(t)\,dt = 1, \qquad \int_0^{\pi} t\Phi_n(t)\,dt \to 0 \qquad (n \to \infty).$$

On dit, après Favard, que ce processus d'approximation est saturé avec un degré de saturation $\varphi(n)$ ($\varphi(n)>0$, $\varphi(n) \to 0$) si, pour toute fonction $f \in C_{2\pi}$ ($f \neq$ const), on a

$$\max_x |U_n(f; x)-f(x)| > a(f)\varphi(n) \quad (a(f) > 0,\ n = 1, 2, \cdots),$$

et s'il existe une fonction $f \in C_{2\pi}$ ($f \neq$ const) telle que

$$(2) \quad \max_x |U_n(f; x)-f(x)| < b(f)\varphi(n) \qquad (n = 1, 2, \cdots).$$

L'ensemble des fonctions satisfaisant à (2) est nommé la classe de saturation $(\Phi_n, \varphi(n))$.

Si l'on ajoute aux hypothèses déjà énumérées la condition que pour chaque σ, $0<\sigma<\pi$,

$$\int_\sigma^{\pi} \Phi_n(t)\,dt = o(\gamma_n), \qquad \gamma_n = \int_0^{\pi} t^2\Phi_n(t)\,dt,$$

alors on constate que le processus d'approximation (1) est saturé avec le degré de saturation γ_n et que la classe de saturation (Φ_n, γ_n) consiste des fonctions $f(x)$ de $C_{2\pi}$ telles que la dérivée $f'(x)$ appartient à la classe Lip 1.

L'auteur énonce un résultat analogue concernant la classe de saturation lorsqu'on itère l'opération U_n; ici il s'appuie sur un travail de A. Tureckiĭ [Izv. Akad. Nauk SSSR Ser. Mat. **25** (1961), 411–442; MR **23** #A1988].

Penkov, B.; Sendov, Bl. 5038

Entropy of the set of continuous functions of several variables. (Russian)

C. R. Acad. Bulgare Sci. **17** (1964), 335–337.

Let Δ be an s-dimensional cube in R_s with edge length l, and let $C_\Delta{}^M$ be the set of all real continuous functions defined on Δ and with values in the interval $[0, M]$. If the distance between two functions is taken to be the Hausdorff distance between their graphs in R_{s+1}, one has the strong equivalences for the entropy and the capacity of the set $C_\Delta{}^M$: $H_\varepsilon(C_\Delta{}^M) \sim C_{2\varepsilon}(C_\Delta{}^M) \sim 2^{-s+1}(l/\varepsilon)^s \log_2(M/2\varepsilon)$. A similar relation holds for a certain class of closed subsets of R_{s+1}. In earlier papers [Bŭlgar. Akad. Nauk. Izv. Mat. Inst. **6** (1962), 27–50; MR **26** #590; Vestnik Moskov. Univ. Ser. I Mat. Meh. **1962**, no. 3, 15–19; MR **25** #3358a], the authors have established this in the case $s=1$. See also Clements [Canad. J. Math. **15** (1963), 422–432; MR **28** #2190]. *G. G. Lorentz* (Syracuse, N.Y.)

Sapogov, N. A. 5039

On the norms of linear polynomial operators associated with problems of approximating continuous functions. I. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **19** (1964), no. 3, 53–68.

Let ϕ_k be a normed orthogonal system of functions on $[a, b]$. For operators $U_n(f, x)$, $f \in C[a, b]$, whose values are polynomials $P_n(x)=\sum_{k=1}^n a_k\phi_k(x)$, the author proves an identity, which, for the trigonometric case, reduces to the identity of Faber, Marcinkiewicz and Zygmund. For this latter case, let $\phi_k(x)=e^{ikx}$, $U_n(\phi_k)=\sum_{|l|\leq n} \gamma_{kl}{}^{(n)}\phi_l$. If

$$\sum_{|k|\leq n} |\gamma_{kk}{}^{(n)}-1|^2 = (4\pi^{-2}\delta_n \log n)^2, \qquad 0 \leq \delta_n \leq 1,$$

and $(1-\delta_n)\log n \to \infty$ as $n \to \infty$, then $\|U_n(f)-f\| \to 0$ cannot hold for all continuous periodic functions f. This generalizes earlier results of the author [Dokl. Akad. Nauk SSSR **143** (1962), 53–55; MR **25** #381a; ibid. **143** (1962), 1286–1288; MR **25** #381b]. Operators for which $U_n(f, x)$ is an algebraic polynomial or a linear combination of characters of a compact abelian group are also studied.

Schoenberg, I. J. 5040

Spline functions and the problem of graduation.

Proc. Nat. Acad. Sci. U.S.A. **52** (1964), 947–950.

Let $I=[a, b]$ and let (x_i, y_i), $i=1, 2, \cdots, n$, be given data with $a \leq x_1 < \cdots < x_n \leq b$. Define $Jf=\int_I [d^mf(x)/dx^m]^2 dx$ and $Ef=\sum_1^n [f(x_i)-y_i]^2$. A natural generalization of Whittaker's method of graduation [Proc. Edinburgh Math. Soc. **41** (1923), 63–75] is to take $m<n$, a parameter $\varepsilon>0$ and determine $f_\varepsilon^*(x)$ so that $\varepsilon Jf+Ef$ is minimized for all

functions f with square integrable mth derivative. The solution $f_\varepsilon^*(x)$ of this problem is the graduation of the data. The main results announced here are: (i) the solution $f_\varepsilon^*(x)$ is a spline function, (ii) the set $\{f_\varepsilon^*(x) | 0 \leq \varepsilon \leq \infty\}$ is the same as the set of solutions g_u^* to the problem: minimize Eg subject to the constraint $Jg = u$ for $0 \leq u \leq Js$, where $s(x)$ is the spline interpolating function $\lim_{\varepsilon\to 0} f_\varepsilon^*(x)$. Proofs and computational remarks for these (and other) results are to appear elsewhere. The periodic case is considered briefly and analogous results announced.

Shapiro, Harold S. 5041

Some negative theorems of approximation theory.

Michigan Math. J. **11** (1964), 211–217.

Let X be a Banach space, $C(T)$ the space of all real continuous functions on a compact (metric) space T, Λ_ω the class of all functions f on T for which $|f(t_1) - f(t_2)| \leq \omega(\rho(t_1, t_2))$, d_n a sequence with $d_n > 0$, $d_n \to 0$. The author proves that if X_n is a sequence of proper closed subspaces of X, then there is an $x \in X$ for which $\rho(x, X_n) \neq O(d_n)$. Let X_n, Y_n be two sequences of finite-dimensional subspaces of $C(T)$, let R_n be the set of all $h = f/g \in C(T)$, $f \in X_n$, $g \in Y_n$. Then for some $f \in C(T)$, $\rho(f, R_n) \neq O(d_n)$. There is also a lower estimate of the degree of approximation of the class Λ_ω by generalized rational functions.

Grišin, V. B. 5042

The approximation of functions of two variables by Fourier sums. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 566–569.

Soit $\bar{H}(\omega_1, \omega_2)$ la classe des fonctions 2π-périodiques par rapport aux x et y satisfaisant aux conditions

$$|f(x_1, y) - f(x_2, y)| \leq \omega_1(|x_2 - x_1|),$$

$$|f(x, y_1) - f(x, y_2)| \leq \omega_2(|y_2 - y_1|),$$

$$|f(x_1, y_1) - f(x_1, y_2) - f(x_2, y_1) + f(x_2, y_2)| \leq \omega_1(|x_2 - x_1|)\omega_2(|y_2 - y_1|).$$

$\omega_1(u)$ et $\omega_2(v)$ sont continues, convexes et telles que $\omega_i(0) = 0$, $0 \leq \omega_i(t_2) - \omega_i(t_1) \leq \omega_i(t_2 - t_1)$, $i = 1, 2$.

On établit la formule asymptotique pour

$$\sup_{f \in \bar{H}} |f(x, y) - S_{m,n}(x, y)|,$$

où $S_{m,n}$ désigne la somme partielle de la série de Fourier de $f(x, y)$ sous la condition que $\lim[\omega_i(\delta) \log 1/|\delta|] = 0$, $\delta \to 0$, $i = 1, 2$.

M. Tomić (Belgrade)

Kokilašvili, V. M. 5043

On a function space and Fourier coefficients. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **35** (1964), 523–530.

The paper contains eight theorems involving $E_n(f)_{L_p}$, i.e., the best approximation of a 2π-periodic function in $L_p(0, 2\pi)$ by trigonometric polynomials of degree $\leq n$, $\omega_k(f, \delta)$, i.e., the modulus of continuity of degree $k \geq 1$ for f in the metric of L_p, and the Banach space $B_{p,\gamma}^{k;\varphi}$, defined as follows: $f \in B_{p,\gamma}^{k;\varphi}$ $(1 \leq \gamma < \infty)$ if

$$\int_0^1 \frac{\omega_k^\gamma(f, t)\varphi(1/t)}{t}\, dt < \infty$$

for every function $\varphi \in L_k^\infty$, where L_k^∞ is defined as the space of non-decreasing functions φ on $[0, \infty)$ with $\varphi(0) = 0$ which fulfill the following conditions: (1) There exists a number $\beta > 0$ such that $t^{-\beta}\varphi(t) = \psi(t)$ is almost increasing on $(0, \infty)$, i.e., there exists a constant A such that $\psi(t_1) \leq A\psi(t_2)$ for all $t_1 \leq t_2 \in (0, \infty)$; (2) There exists a number α, $0 < \alpha < k$, such that $\mu(t) = t^{\alpha - k}\varphi(t)$ is almost decreasing on $(0, \infty)$, i.e., $\mu(t_1) \geq B\mu(t_2)$ for all $t_1 \leq t_2 \in (0, \infty)$. Two typical results are the following. (1) If $f \in L_p(0, 2\pi)$ and $f = F + T_1$, where T_1 is the trigonometric polynomial of degree one of best approximation in L_p for f, then

$$A \int_0^1 \frac{\omega_k^\gamma(F, t)\varphi^\gamma(t^{-1})}{t}\, dt \leq \sum_{s=0}^{\infty} E_{2^s}^\gamma(f)_{L_p}\varphi^\gamma(2^s) \leq B \int_0^1 \frac{\omega_k^\gamma(f, t)\varphi^\gamma(t^{-1})}{t}\, dt.$$

(2) If $f \sim \sum_1^\infty b_n \sin nx$ and if there exists a $\tau > 0$ such that $n^{-\tau}b_n \downarrow 0$, then $f \in B_{p,p}^{k;\varphi}$ if and only if $\sum_{k=1}^\infty b_k^p k^{p-2}\varphi^p(k) < \infty$.

Pavlovs'kii, M. M. [Pavlovskii, N. M.] 5044

On the approximation of functions satisfying a Lipschitz condition by trigonometric polynomials. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1963**, 1311–1315.

Soient KH^α la classe des fonctions 2π-périodiques satisfaisant à la condition de Lipschitz d'ordre α $(0 < \alpha \leq 1)$ et

$$T_n^N(f, x) = \frac{2}{N} \sum_{k=1}^{N} f(x_k) D_n(x - x_k),$$

$$x_k = 2k\pi/N, \ k = 1, 2, \cdots, N \leq 2n.$$

D_n est le noyau de Dirichlet. L'auteur donne la formule asymptotique pour $E_n^N(x) = \sup_{f \in KH^\alpha} |f(x) - T_n^N(f, x)|$.

M. Tomić (Belgrade)

Videnskii, V. S. 5045

On trigonometric polynomials of half-integer order. (Russian. Armenian summary)

Izv. Akad. Nauk Armjan. SSR Ser. Fiz.-Mat. Nauk **17** (1964), *no.* 3, 133–140.

L'auteur étudie certains problèmes extrémaux dans la classe $T(n + \frac{1}{2})$ des polynômes trigonométriques ayant la forme

$$s(t) = \sum_{k=0}^{n} (a_k \cos(k + \tfrac{1}{2})t + b_k \sin(k + \tfrac{1}{2})t).$$

(1) Si $s(t)$ appartient à $T(n + \frac{1}{2})$ et si $|s(t)| \leq 1$ $(-\beta \leq t \leq \beta$, $0 < \beta < \pi)$, alors

$$|s'(t)| \leq \frac{(n + \frac{1}{2}) \cos \frac{1}{2}t}{\sqrt{(\sin^2 \frac{1}{2}\beta - \sin^2 \frac{1}{2}t)}}$$

$(-\beta < t < \beta)$. La signe d'égalité a lieu seulement pour

$$\tau_{2n+1}(t) = \gamma \cos(2n + 1)\text{arc}\cos(\sin \tfrac{1}{2}t/\sin \tfrac{1}{2}\beta)$$

$(-\beta \leq t \leq \beta$, $|\gamma| = 1)$, et seulement en les $2n + 1$ zéros de

$\tau_{2n+1}(t)$ sur le segment $[-\beta, \beta]$. (2) Dans l'hypothèse de (1), on a

$$|s'(t)| \leq \tfrac{1}{2}(2n+1)^2 \operatorname{ctg} \tfrac{1}{2}\beta = \tau'_{2n+1}(\beta) \qquad (-\beta \leq t \leq \beta),$$

pourvu que n soit supérieur à $\frac{1}{2}\sqrt{(3 \operatorname{tg}^2 \frac{1}{2}\beta + 1)}$. (3) L'auteur donne également la solution de la question (1) pour une majoration $|s(t)| \leq h(t)$, $h(t)$ étant donné dans la classe $T(m+\frac{1}{2})$, $m \leq n$.

E. J. Akutowicz (Bologna)

Aljančić, S.; Tomić, M. 5046

Sur le module de continuité intégral des séries de Fourier à coefficients convexes.

C. R. Acad. Sci. Paris **259** (1964), 1609–1611.

Suppose that $\mu(x)$ $(x \geq 0)$ satisfies the conditions: (1) $0 < \mu(x) \searrow 0$ as $x \to +\infty$; (2) $\mu(x)$ is convex; and (3) $\int_1^x \mu(t)\,dt = O[x\mu(x)]$. Then one of the main theorems of the authors is as follows. Set

$$f(x) = \frac{\mu_0}{2} + \sum_{n=1}^{\infty} \mu_n \cos nx, \qquad \mu_n = \mu(n).$$

Then $f(x)$ is L-integrable in $(0, \pi)$ and

$$\sup_{|t| \leq \pi/n} \int_0^{\pi} |f(x+t) - f(x)|\, dx = O(\mu_n).$$

The integral modulus of continuity of the sine series is also given from its Fourier coefficients. From these results and the Young theorem on convolution, the authors derive the integral modulus of continuity of such series as

$$\sum \mu_n(a_n \cos nx + b_n \sin nx)$$

under appropriate conditions. This gives an alternative proof of a theorem by S. Aljančić [Math. Z. **81** (1963), 215–222; MR **27** #1774].

G. Sunouchi (Sendai)

Mitjagin, B. S. 5047

On the absolute convergence of the series of Fourier coefficients. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1047–1050.

The main result of this paper is the following generalization of the "negative" part of the classical result of Bernstein [C. R. Acad. Sci. Paris **199** (1934), 397–400]. Let $\Psi = (\psi_n)$ be an arbitrary complete orthonormal system of functions defined on the interval $[0, 2\pi]$. Then there exists a function f in $C^{1/2}(0, 2\pi)$ such that

$$\sum_{n=1}^{\infty} \left| \int_0^{2\pi} f(t)\psi_n(t)\, dt \right| = +\infty,$$

where $C^{1/2}(0, 2\pi)$ denotes the class of all complex-valued 2π-periodic functions such that

$$\sup_{0 \leq h \leq 2\pi} \sup_{0 \leq t \leq 2\pi} |f(t+h) - f(t)| h^{-1/2} < +\infty.$$

The proof of this result is as follows. Suppose that for some Ψ the assertion of the theorem is false. Then the linear operator $I: C^{1/2} \to l_1$, with $If = (\int_0^{2\pi} f(t)\psi_n(t)\, dt)$, is well-defined. Let us consider the diagram

$$\begin{tikzcd} & C^{1/2} \arrow[r, "I"] & l_1 \arrow[dr, "J"] & \\ L_\infty \arrow[ur, "\Lambda"] \arrow[rrr, "\tilde{\Lambda}"] & & & l_2 \end{tikzcd}$$

where Λ is the operator of multiplication; $\Lambda(1) = 1$, $\Lambda(e^{int}) = |n|^{-1/2} e^{int}$ $(n = \pm 1, \pm 2, \cdots)$; J is the natural (identical) embedding of l_1 into l_2; $\tilde{\Lambda}(f) = (c_n)$, where $c_0 = \int_0^{2\pi} f(t)\, dt$ and $c_n = n^{-1/2} \int_0^{2\pi} f(t) e^{int}\, dt$ $(n = \pm 1, \pm 2)$. Then Λ is continuous [A. Zygmund, *Trigonometric series*, Vol. II, p. 136, second edition, Cambridge Univ. Press, New York, 1959; MR **21** #6498], and J maps every unconditionally convergent series into an absolutely convergent one [the reviewer and W. Szlenk, Colloq. Math. **10** (1963), 313–323; MR **29** #452]. Therefore, $\tilde{\Lambda}$ would map every unconditionally convergent series into an absolutely summable one, but this contradicts the inequality $\sum_{n=1}^{N} \|\tilde{\Lambda}\chi_n\| \geq (\log \frac{1}{2}N)^{1/2}$, where χ_n denotes the characteristic function of the interval $[2\pi(n-1)/N, 2\pi n/N]$ $(n = 1, 2, \cdots, N;\ N = 1, 2, \cdots)$. A similar result for orthonormal systems of functions of several variables is also given.

A. Pełczyński (Warsaw)

Pippert, Raymond E. 5048

On absolutely convergent trigonometric series.

Math. Z. **85** (1964), 401–406.

The well-known theorem of Fatou is as follows. Let the sequence $\{a_n\}$ satisfy $|a_{n+1}| \leq |a_n|$ for all n. If either $\sum |a_n \cos nx_0| < \infty$ for some x_0 or $\sum |a_n \sin nx_0| < \infty$ for some $x_0 \neq 0 \pmod{\pi}$, then $\sum |a_n| < \infty$. The author generalizes the condition $|a_{n+1}| \leq |a_n|$, replacing it by $|a_{n+1}| \leq K|a_n|$ for a constant K independent of n, and shows that this new condition is the best possible in a sense. Another such generalization is given also in a theorem of Salem.

However, as the author has remarked in proof, part of the result is not new. In particular, the original idea of such a generalization is due to O. Szász [Ann. of Math. (2) **47** (1946), 213–220; MR **7**, 435].

G. Sunouchi (Sendai)

Takeda, Kazuaki; Takeda, Zirô 5049

A certain series of multiplicatively orthogonal functions.

Tôhoku Math. J. (2) **16** (1964), 34–59.

An orthonormal set $\{\varphi_{n,1}(x)\}_1^{\infty}$ is defined on $[0, 1]$, each function taking the values $\sqrt{2}$, 0, $-\sqrt{2}$ on intervals of length $\frac{1}{4}$, $\frac{1}{2}$, $\frac{1}{4}$. Analogous to the completion of the Rademacher functions by the Walsh functions, this set is completed by setting $\varphi_{n,2}(x) = \varphi^2_{n,1}(x) - 1$ and taking the collection of all finite products $\{\varphi_{n_1,i_1}\varphi_{n_2,i_2} \cdots \varphi_{n_k,i_k}\}$, $n_1 > n_2 > \cdots > n_k \geq 0$, $i_j = 1$ or 2, $\varphi_{0,i}(x) \equiv 1$. Let $\{\psi_n(x)\}_0^{\infty}$ denote the complete system. The following inequality is established, analogous to one proved by Paley for the Walsh functions. If $f \in L^p[0, 1]$, $1 < p < \infty$, and $f \sim \sum_0^{\infty} c_n\psi_n$, then

$$B_p \int_0^1 \left(\sum_0^{\infty} \Delta_n^2(x) \right)^{p/2} dx < \int_0^1 |f(x)|^p\, dx < B_p' \int_0^1 \left(\sum_0^{\infty} \Delta_n^2(x) \right)^{p/2} dx,$$

where B_p and B_p' are constants, and $\Delta_n(x) = \sum_{3^n}^{3^{n+1}-1} c_j\psi_j(x)$. More general orthonormal sets of step functions were studied by Ohkuma [same J. (2) **5** (1953), 166–177; MR **15**, 867].

A new proof of a theorem on the absolute summability factors of Fourier series.

Riv. Mat. Univ. Parma (2) 4 (1963), 149–158.

T. Pati and S. R. Sinha proved a theorem on the Cesàro absolute summability factors of Fourier series [Indian J. Math. 1 (1958), no. 1, 41–54; MR **22** #2837 (where the result is quoted in full)]. Here is presented a different and shorter proof of the same theorem. *L. Lorch* (Aarhus)

Sahney, B. N. 5052

On the relation between Riemann and Abel summability of trigonometrical series.

Ann. Mat. Pura Appl. (4) **63** (1963), 123–131.

Let p be an integer ≥ 1 and s_n the nth partial sum of the series $\sum a_n$. The series $\sum_{n=1}^{\infty} a_n$ is said to be summable (R', p) to the sum zero if the series $t\sum_{\nu=1}^{\infty} s_\nu(\sin \nu t/\nu t)^p$ converges for small $t>0$ and tends to zero as $t \to 0$. The author proves that if the series $\sum a_n$ is Abel summable and if $\sum_n^{2n}(|a_\nu| - a_\nu) = O(1)$, then the series is summable (R', p) to the same value for any integer $p \geq 1$.

The theorem of du Bois-Reymond for generalized integrals and trigonometrical series which are Abel-Poisson summable. (Russian. English summary)

Vestnik Moskov. Univ. Ser. I Mat. Meh. **1964**, *no.* 4, 16–20.

Main result: There is a trigonometric series which is A-summable for each $x \in [0, 2\pi]$ to a finite and D-integrable function $f(x)$ but which is not the Denjoy-Fourier series of $f(x)$. *N. Dinculeanu* (Bucharest)

Matuš̌ů, Josef 5054

Das Dinische Integral und die Frage der Konvergenz des Fourierschen Integrals.

Publ. Math. Debrecen **10** (1963), 203–214.

Suppose that the function f is (L) integrable in $(-\infty, \infty)$ or that f is integral in any finite interval and is of bounded variation in $(-\infty, h)$ and (h, ∞), tending to zero as $t \to \pm\infty$. It is well known that if the Dini integral

$$\int_0^d \frac{(f(t+x)+f(t-x)-2f(t))}{x}\,dx$$

exists as the Lebesgue integral (absolutely convergent integral), then the Fourier integral

$$\frac{1}{\pi}\int_0^{\infty} dy \int_{-\infty}^{\infty} f(x)\cos y(x-t)\,dx$$

converges to $f(t)$.

The author gives an example of a function f such that, at a fixed point t, (i) the Dini integral exists as the conditionally convergent integral for a finite d, but (ii) the Fourier integral does not converge.

(I) is the generalization of Kac, Salem and Zygmund [Trans. Amer. Math. Soc. **64** (1948), 235–243; MR **9**, 426] and (III) generalizes the reviewer's theorem [Tôhoku Math. J. (2) **3** (1951), 89–103; MR **14**, 868].

Šilov, G. E. 5055

On the Fourier transform theory of infinitely differentiable, rapidly decreasing functions. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1961**, *no.* 3 (22), 174–176.

In their book on generalized functions, Gel'fand and Šilov [*Generalized functions*, Vol. 1 (Russian), Fizmatgiz, Moscow, 1958; MR **20** #4182] study the classes $S_{\alpha,A}^{\beta,B}$ of infinitely differentiable functions $\phi(x)$ $(-\infty < x < \infty)$ satisfying the conditions

$$|x^k\phi^{(q)}(x)| \leq CA_1{}^kB_1{}^qk^{k\alpha}q^{q\beta} \quad (k, q = 0, 1, 2, \cdots)$$

for any $A_1 > A$, $B_1 > B$ and C independent of A_1 and B_1. They prove that if $\alpha > 0$, $\beta > 0$ and $\alpha+\beta > 1$, then the Fourier transform takes $S_{\alpha,A}^{\beta,B}$ onto itself. The author shows here that this remains true for $\alpha \geq 0$, $\beta \geq 0$ and $\alpha+\beta > 1$. *A. Devinatz* (St. Louis, Mo.)

Bredihina, E. A. 5056

On the approximation of almost periodic functions. (Russian)

Sibirsk. Mat. Ž. 5 (1964), 768–773.

Let Q denote the set of uniformly almost periodic functions, B_σ the set of entire functions of degree $\leq \sigma$, bounded on the whole real line, and $L(f)$ the set of absolute values of Fourier coefficients of $f \in Q$. Let us write

$$A_\sigma(f) = \inf_{\varphi \in B_\sigma} \sup_x |f(x) - \varphi(x)|,$$

$$R_\sigma(f) = \sup_x |f(x) - f_\sigma(x)|,$$

where $f_\sigma \in B_\sigma$ is a uniformly almost periodic function with Fourier series $\sum_{|\lambda_k| \leq \sigma} a_k e^{i\lambda_k x}$. A positive number σ is called an isolated point of $L(f)$ if there exists $\varepsilon > 0$ such that the interval $(\sigma, \sigma+\varepsilon)$ does not contain points from $L(f)$. In the paper under review estimations of the following type $R_\sigma(f) \leq \phi(\sigma, L(f)) \cdot A_\sigma(f)$, where σ denotes the isolated point of $L(f)$, are investigated. The results are too complicated to be quoted here. *J. Albrycht* (Poznań)

Hartman, S.; Ryll-Nardzewski, C. 5057

Almost periodic extensions of functions.

Colloq. Math. **12** (1964), 23–39.

Let R be the real line. I is the class of all sets $A \subseteq R$ such that every bounded real- or complex-valued function on A which is uniformly continuous can be extended to an almost periodic (a.p.) function on R. Property I has been considered hitherto only for the case when A is a sequence of positive numbers. In this case Strzelecki [same Colloq. **11** (1963), 91–99; MR **28** #3294] has proved that $\{a_1, a_2, \cdots\} \in$ I if (*) $a_{n+1}/a_n \geq c > 1$ for $n = 1, 2, \cdots$. The authors show that $A \in$ I if there exists an $\alpha > 0$ such that $\{X \subseteq A : \inf\{|x-y| : x \neq y,\ x, y \in X\} \geq \alpha\} \subseteq$ I. Both results give, e.g., that $\bigcup_{n=1}^{\infty} I_n \in$ I whenever I_n is a sequence of

intervals of bounded length such that some sequence $a_n \in I_n$ $(n = 1, 2, \cdots)$ satisfies (*).

Similar results are obtained for almost periodicity in the sense of Stepanoff and Riemann-Stepanoff.

For any Abelian topological group G let $\mathrm{I}(G)$ denote the class of all sets $A \subseteq G$ such that every bounded real- or complex-valued function on A can be extended to a continuous a.p. function on G (thus $\mathrm{I}(R) \subset \mathrm{I}$). It is shown that $A \in \mathrm{I}(G)$ if and only if every function on A taking only the values 0 or 1 can be extended to a continuous a.p. function on G; if G is discrete, then there are $A \in \mathrm{I}(G)$ such that $\operatorname{card} A = \operatorname{card} G$; if G is compact and its topological weight is at least $2^{\aleph_0}$, then there is an infinite set $A \in \mathrm{I}(G)$. In several proofs the Bohr compactification is used. Some open problems are mentioned. Related investigations concerning extensions to continuous periodic functions are quoted. *J. Mycielski* (Wroclaw)

Kovalenko, M. K. 5058

Approximate construction of polynomials of best approximation. (Russian)

Uspehi Mat. Nauk **18** (1963), *no.* 6 (114), 201–207.

The author describes several algorithms for the construction of polynomials of best uniform approximation that can be realized on high-speed computers. Let E_m be a finite set of abscissas $u_1, u_2, \cdots, u_m$, with $u_i < u_{i+1}$, and let $f(u)$ be a real-valued function defined on E_m. The problem is to determine the polynomial P^* of degree $\leq n$, where $n < m-2$, which best approximates f on E_m. The author introduces the set G_n of all possible $(n+2)$-tuples $x = (u_{k_1}, u_{k_2}, \cdots, u_{k_{n+2}})$ of abscissas, where $1 \leq k_1 < k_2 < \cdots < k_{n+2} \leq m$. With every $x \in G_n$ there is an easily determined polynomial $P_x(u)$ of degree $\leq n$ which best approximates f on the components of x; the corresponding deviation is denoted by $L_n(f; x)$. It is well known that the polynomial P^* may be characterized as the polynomial P_x associated with an $(n+2)$-tuple x for which $L_n(f; x)$ is a maximum. The author gives a detailed definition of a number of operators Γ which take G_n into itself and have the following property. Whenever $L_n(f; x) > 0$ and $P_x \neq P^*$, then $L_n(f; \Gamma x) > L_n(f; x)$. It follows that a finite number of applications of one of the operators Γ takes x into an $(n+2)$-tuple y such that $P_y = P^*$. The methods are used to obtain approximate polynomials of best approximation on an interval. *J. Korevaar* (La Jolla, Calif.)

Taberski, R. 5059

On double integrals and Fourier series.

Ann. Polon. Math. **15** (1964), 97–115.

Let a function $f(x, y)$ be plane-measurable with respect to Lebesgue measure in the rectangle $R = [a, b; c, d]$ and let

$$\mu\{(x, y) \in R\colon |f(x, y)| > n\} = o\left(\frac{1}{n}\right) \quad \text{as } n \to \infty.$$

Write

$$[f(x, y)]_n = f(x, y), \qquad |f(x, y)| \leq n,$$
$$= 0, \qquad |f(x, y)| > n.$$

If the Lebesgue integrals

$$(\mathrm{L}) \int_a^s \int_c^t [f(x, y)]_n \, dxdy, \qquad (s, t) \in R,$$

tend uniformly to a limit $F(s, t)$ as $n \to \infty$ in R, then f said to be T-integrable on R and F is denoted by

$$(\mathrm{T}) \int_a^b \int_c^d f(x, y) \, dxdy.$$

Suppose that the functions $g_n(x, y)$ of bounded variation in $R = [a, b; c, d]$ are uniformly bounded in R for $n = 1, 2, \cdots$. Moreover, let the variations

$$\int_a^b \int_c^d |dg_n(x, y)|, \quad \int_a^b |dg_n(x, d)|, \quad \int_c^d |dg_n(b, y)|$$

remain uniformly bounded for $n = 1, 2, \cdots$, and let

$$\lim_{n \to \infty} (\mathrm{L}) \int_a^\alpha \int_c^\gamma g_n(x, y) \, dxdy = 0$$

for each $(\alpha, \gamma) \in R$. Then the author proves that

$$\lim_{n \to \infty} (\mathrm{T}) \int_a^b \int_c^d f(x, y) g_n(x, y) \, dxdy = 0$$

for any T-integrable f on R. Besides this, the author obtains a number of results on two-dimensional analogues of Riemann-Stieltjes, Lebesgue and Titchmarsh integrals. He further establishes some relations between certain classes of functions and classes of Fourier coefficients of a double Fourier series corresponding to these classes. *B. N. Prasad* (Allahabad)

Wik, Ingemar 5060

Some examples of sets with linear independence.

Ark. Mat. **5**, 207–214 (1964).

A set E is called a uniform Kronecker set if, to every continuous function f on E, of absolute value 1, and to every $\varepsilon > 0$, there corresponds a real number t such that

$$\sup_{x \in E} |f(x) - e^{itx}| < \varepsilon.$$

A set E is called a Kronecker set if

$$\inf_{\mu \in \Gamma_0} \sup_n \left| \int_E e^{inx} \, d\mu(x) \right| = 1.$$

Here Γ_0 is the class of functions μ which are constant outside E and $\int_E |d\mu| = 1$. The author proves the following results: (1) If E is a uniform K-set, then $E \cup \{0\}$ is a K-set, but the converse is not true; (2) There exists no maximal uniform K-set; (3) Let h be a continuous positive increasing function defined for $r \geq 0$ such that $h(0) = 0$ and $\lim_{r \to 0} h(r)/r = \infty$. There exists then a perfect uniform K-set of E of positive Hausdorff measure with respect to the measure function h $(M_h(E) > 0)$. *N. Dinculeanu* (Bucharest)

Korotkov, V. B.; Gil'derman, Ju. Ĭ. 5061

The Fourier transform for abstract set functions. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 844–852.

By means of a correspondence (established in their previous paper [Gil'derman and Korotkov, same Ž. **4** (1963), 1426–1430; MR **28** #2431]) between the spaces of abstract set functions $\phi_p(X, \Omega)$ and the spaces of linear operators $(L_{p'}(\Omega) \to X)$, the authors construct Fourier transforms for

abstract set functions from ϕ_p, $1 \leq p \leq 2$. Thus, fundamental theorems concerning Fourier transforms of numerical functions are generalized for Fourier transforms of abstract set functions. *J. Albrycht* (Poznań)

Beurling, Arne 5062f
Analyse harmonique de pseudomesures. Intégration.
C. R. Acad. Sci. Paris **258** (1964), 3423–3425.

L'auteur appelle pseudomesure toute distribution df sur la droite dont la primitive f est localement sommable. Etant donné un espace de Banach B de pseudomesures, et un compact E sur la droite, il note B_E le sous-espace de B constitué des pseudomesures dans B à support dans E, et pose les problèmes suivants: (1) Pour quels ensembles E a-t-on $B_E=\{0\}$? (2) Si $B_E \neq \{0\}$, B_E contient-il nécessairement des mesures positives? (3) ("Synthèse spectrale") Les combinaisons linéaires de mesures positives $\mu \in B_E$ sont-elles denses dans B_E?

Les notes 1 et 2 sont consacrées à un théorème fondamental (théorème 1 et corollaire). Etant donné une famille M de fonctionnelles $df \to m(df) = \int_{-\infty}^{\infty} \Phi(|f(t+\tau) - f(t)|)dt$ définies chacune par une fonction Φ strictement convexe, paire, différentiable, nulle en 0, et par un nombre $\tau \in [0, 1]$, on dit que df est une M-minorante intérieure de dg si (1°) pour toute $m \in M$, $m(df) \leq m(dg)$, (2°) df est portée par le support de dg. Alors toute pseudomesure $dg \neq 0$ admet une M-minorante intérieure df qui est une mesure positive. Plus précisément, si dg est portée par $[-a, a]$, df maximise, sur l'ensemble des M-minorantes intérieures de dg, les formes linéaires $df \to \int \varphi df$, où φ est une fonction concave positive sur $[-a-1, a+1]$ (l'intervention de la concavité de φ dans la démonstration peut causer au lecteur une certaine surprise).

La note 3 répond aux problèmes 1 et 2 lorsque $B = \hat{B}_\alpha$ $(0 \leq \alpha \leq 1)$, l'ensemble des transformées de Fourier des fonctions F localement de carré sommable telles que $\|F\| = \sup_{T \geq 1} (\frac{1}{2} T^{-\alpha} \int_{-T}^{T} |F|^2)^{1/2} < \infty$. La réponse au problème 1 fait intervenir une "mesure préhausdorffienne" de dimension $1-\alpha$, notion ad hoc, et la réponse au problème 2 est positive.

Les trois dernières notes sont consacrées à la synthèse spectrale. Etant donné une fonction $\varphi(t)$ continue $(t \geq 0)$ telle que $0 = \varphi(0) \leq \varphi(t) \leq \varphi(t+t') \leq \varphi(t) + \varphi(t')$, on désigne par $\mathscr{C}_\varphi^0$ l'espace de Banach des pseudomesures df dont les primitives satisfont

$$\lim_{t' \to t} |f(t') - f(t)|/\varphi(|t'-t|) = 0,$$

$$(\|df\| = \sup_{t,t'} |f(t') - f(t)|/\varphi(|t'-t|)).$$

Par un procédé explicite et élémentaire, l'auteur montre que la réponse au problème 3 est positive si $B = \mathscr{C}_\varphi^0$. Ce procédé lui permet de plus de définir l'intégrale $\int_0^1 g(t)\,df(t)$ sous la conditions $\int_0^1 \varphi_f(s)^{-1} d\varphi_g(s) < \infty$ (φ_f = module de continuité de f), plus large que la condition classique de Young (note 4).

Plus généralement (note 5), l'auteur définit une intégrale $\mathbf{S} g\,df$ sous la condition (*) $\int_0^\infty \|g, \tau\| \|f, \tau\| \tau^{-2} d\tau$, où $\|f, \tau\|^2 = \int |f(t+\tau) - f(t)|^2 dt$. Cette intégrale peut être définie par transformation de Fourier. Sa propriété la plus importante est une sorte de théorème de Lebesgue, affirmant, sous certaines conditions, que $\mathbf{S} g_n\,df_n$ tend vers $\mathbf{S} g\,df$.

On peut donner (note 6) des conditions sur les transformées de Fourier de g et df, garantissant (*). On en déduit une réponse positive au problème 3 pour tous les espaces B tels que (1°) B contient topologiquement $\mathscr{F}L^\infty$, (2°) toute fonctionnelle linéaire sur B s'écrit $df \to \int_{-\infty}^{\infty} G(-x)F(x)dx$, où F est la transformée de Fourier de df, et F et G satisfont

$$\int_{-\infty}^{\infty} |G(x)|^2 \lambda(x)\,dx \int_{-\infty}^{\infty} |F(x)|^2 \lambda^{-1}(x)\,dx < \infty,$$

$\lambda(x)$ étant une fonction paire, continue, positive, égale à 1 sur $[-1, 1]$ et satisfaisant $0 < \varepsilon \leq d \log \lambda(x)/d \log x \leq 2 - \varepsilon$ sur $[1, \infty[$. Cela vaut en particulier pour $B = \hat{B}_0^\alpha$ $(1 < \alpha < 2)$, l'espace des df dont les transformées de Fourier F satisfont $\int_{-T}^{T} |F(x)|^2 dx = o(T^\alpha)$ $(T \to \infty)$.

Cette série de notes est rédigée de façon assez détaillée pour que—sauf peut-être à la fin—le lecteur ait tous les éléments des démonstrations. On ne peut que souhaiter voir d'autres œuvres inédites de l'auteur paraître dans un proche avenir. *J.-P. Kahane* (Orsay)

Artiaga, Lucio 5064
Generalized Hilbert kernels.
Duke Math. J. **31** (1964), 471–478.

It is shown that if $f(x) \in L^2(0, \infty)$, the formula

$$G(x) = \operatorname{sgn} x f(x) - \frac{1}{\pi^2} \int_{-\infty}^{\infty} \frac{\log x^2 - \log t^2}{x - t} f(t)\,dt$$

defines for all real non-zero x a function $G(x)$ of $L^2(0, \infty)$, and the reciprocal formula, in which f and G are interchanged, holds almost everywhere.

The Mellin transform of any Fourier kernel $k(x)$ satisfies $k^*(s)k^*(1-s)=1$. Taking $k^*(s)=\cot \frac{1}{2}\pi s$, we obtain the Hilbert kernel $k(x)=2/(\pi-\pi x^2)$. The above formulae arise when $k^*(s)=\cot^2 \frac{1}{2}\pi s$, and the author remarks that similar results could be obtained by taking $k^*(s)=\cot^n \frac{1}{2}\pi s$ with $n=3, 4, 5, \cdots$. *P. Heywood* (Edinburgh)

Joshi, J. M. C. 5065

On a generalized Stieltjes transform.

Pacific J. Math. **14** (1964), 969–975.

The principal theorem proved by the author is that if

$$(1) \qquad \phi(s) = \int_0^\infty e^{-sx} F(x)\, dx,$$

where

$$(2) \quad F(x) = [\Gamma(\beta+\eta+1)/\Gamma(\alpha+\beta+\eta+1)] \times \int_0^\infty (xy)^\beta {}_1F_1(\beta+\eta+1;\alpha+\beta+\eta+1;-xy) f(y)\, dy \quad (\beta \geqq 0, \eta > 0),$$

then

$$(3) \quad \phi(s) = [\Gamma(\beta+\eta+1)/\Gamma(\alpha+\beta+\eta+1)][\Gamma(\beta+1)/s] \times \int_0^\infty (y/s)^\beta F(\alpha, \beta+1; b; -y/s) f(y)\, dy,$$

which is termed a generalized Stieltjes transform.

Inversion formulas for (2), which reduce to the Laplace transform $F(x)=\int_0^\infty e^{-xy}f(y)dy$ for $\alpha=\beta=0$, as well as for (3), are also obtained. *E. J. Scott* (Urbana, Ill.)

Joshi, J. M. C. 5066

Inversion and representation theorems for a generalized Laplace transform.

Pacific J. Math. **14** (1964), 977–985.

Using operators defined by H. Kober [Quart. J. Math. Oxford Ser. **11** (1940), 193–211; MR **2**, 191], the author obtains an inversion formula and a representation theorem for the transform

$$F(x) = \frac{\Gamma(\beta+\eta+1)}{\Gamma(\alpha+\beta+\eta+1)} \times \int_0^\infty (xy)^\beta {}_1F_1(\beta+\eta+1;\alpha+\beta+\eta+1;-xy) f(y)\, dy$$

$(\beta \geq 0, \eta \geq 0)$, which reduces to the Laplace transform $F(x)=\int_0^\infty e^{-xy}f(y)dy$ when $\alpha=\beta=0$.

A division algebra for sequences and its associated operational calculus.

Amer. Math. Monthly **71** (1964), 719–728.

Der Verfasser ersetzt in der Operatorenrechnung von J. Mikusiński die Funktionen durch Folgen und das Faltungsprodukt durch das Cauchy-Produkt. Er erhält so ein diskretes Analogon, mit dessen Hilfe sich lineare Differenzengleichungen mit konstanten Koeffizienten auflösen lassen. Diese Übertragung wurde bereits von verschiedenen Autoren vorgenommen und ist (in etwas abgeänderter Bezeichnungsweise) auch in dem Buch [*Einführung in die Operatorenrechnung*, VEB Deutscher Verlag der Wissenschaften, Berlin, 1962; MR **25** #5347] des Referentes zu finden. *L. Berg* (Halle)

Gesztelyi, Ernő 5070

Anwendung der Operatorenrechnung auf lineare Differentialgleichungen mit Polynom-Koeffizienten.

Publ. Math. Debrecen **10** (1963), 215–243.

This paper fills a gap left in the two standard texts of Mikusiński [*Operational calculus*, Pergamon, New York, 1959; MR **21** #4333] and Erdélyi [*Operational calculus and generalized functions*, Holt, Rinehart & Winston, New York, 1962; MR **26** #557].

The algebraic derivative of an operator is defined by $D\{f(t)\}=\{-tf(t)\}$, together with the usual formula for products and quotients. The algebraic (indefinite) integral $b=\int a$ is taken to mean $Db=a$.

In Section 1, the author starts with the definition and develops operational and existence theorems. His final result is that the distribution operators, i.e., those of the form $h^{-\lambda}f/l^k$, where $h=e^{-s}$ is the shift operator $l=\{1\}$ and f is a continuous function, are algebraically integrable.

In Section 2, the author examines functions of the type $f(t)/(-t)^n$, where $f(t) \in C^\infty$. Starting with a chosen ("bezeichnete") integral of $1/s$, an iterated starred integral $\int_*^n f$ is defined, so that we may define $\{f(t)/(-t)^n\}=\int_*^n f$ to be continuous. (This treatment is related to the finite part of an expression.)

In Section 3, the algebraic logarithm is introduced in the form that if $a=Dw/w$, then $\log w=\int a$ (which is not unique). There follows a discussion of sequences of logarithms and "algebraic powers".

The final Section 4 contains some applications of the previous work to the solution of differential equations.

J. L. Griffith (Lawrence, Kans.)

Sur une extension du calcul opérationnel.

Rend. Mat. e Appl. (5) **22** (1963), 382–391.

It is supposed that $f(t)$, defined on $0 \leq t \leq \infty$, is continuous except for a finite number of algebraic singularities (at

points a_j), i.e., at each point a_j there exist positive numbers r_j and ρ_j such that

$$\lim_{t\to a_j+0} (t-\tau_j)^{r_j} f(t), \qquad \lim_{t\to a_j-0} (t-\tau_j)^{\rho_j} f(t)$$

are finite. Using Hadamard's definition of Pf ("partie finie") the convolution $t^n * f(t)$ is defined by

$$\sum_{a_j<t}\left[\mathrm{Pf}\int_{a_{j-1}}^{a_j} (t-\tau)^n f(\tau)\,d\tau + \mathrm{Pf}\int_{a_j}^{a_j} (t-\tau)^n f(\tau)\,d\tau\right] + \mathrm{Pf}\int_{a_j}^{t} (t-\tau)^n f(t)\,dt.$$

Using the notation of Mikusiński, the author defines $\{f(t)\}$ by $(1/n!)s^n * t^n * f(t)$. This definition is connected with the idea of regularisation [Gel'fand and Shilov, *Generalized functions*, Vol. I, p. 45 et seq., Academic Press, New York, 1964; MR **29** #3869]. It is now possible to extend Mikusiński's operational calculus by these new operators.

The author notes that there is some connection between his work and that of Gesztelyi [#5070]. He is also able to solve a certain equation of the Volterra type.

J. L. Griffith (Lawrence, Kans.)

Vu, Tuan 5072

On a theorem of the operational calculus. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1963**, 1315–1317.

Assume that

$$(1) \qquad f(t) = \frac{1}{2\pi i}\int_{\sigma-i\infty}^{\sigma+i\infty} e^{pt}F(p)\,dp,$$

where σ is greater than the order of growth of $f(t)$;

$$(2) \qquad \int_{\sigma-i\infty}^{\sigma+i\infty} e^{pt}F(p)\,dp$$

is differentiable for $t \geqq 0$;

$$(3) \qquad \Phi(p, w) = \int_0^\infty e^{q(t)w}t^{-1}e^{-pt}\,dt,$$

where $q(t)$ is bounded and differentiable for $t \geqq 0$ and $q(t) \equiv 0$ for $t < 0$. The author then proves that

$$f[q(t)] = \frac{1}{4\pi^2}\int_{\sigma-i\infty}^{\sigma+i\infty} e^{pt}\left\{\int_{\sigma-i\infty}^{\sigma+i\infty} F(w)\frac{d}{dp}\Phi(p, w)\,dw\right\}dp.$$

Ashour, Attia A. 5075

An integral equation for the associated Legendre function of the first kind.

J. Mathematical Phys. **5** (1964), 1421–1423.

The solution of the homogeneous Fredholm equation

$$\psi(\xi) = \lambda\int_0^1 M(\xi, \xi')\psi(\xi')\,d\xi',$$

where

$$M(\xi, \xi') = \int_0^\pi \frac{\cos m\phi\,d\phi}{(x^2 - 2xx'\cos\phi + x'^2)^{1/2}}$$

and $x = (1-\xi^2)^{1/2}$, is found to be the associated Legendre function $P_n^m(\xi)$, $n+m$ even, and the characteristic numbers of this kernel are obtained. The solution of the corresponding inhomogeneous equation is then found. Finally, the kernel of a homogeneous equation whose solution is $P_n^m(\xi)$, $n+m$ odd, is obtained. The integral equations considered arise in various branches of electromagnetism.

W. D. Collins (Manchester)

Über eine singuläre Integralgleichung mit Anwendung in der Theorie des schwingenden Gitters.

Wiss. Z. Martin-Luther-Univ. Halle-Wittenberg Math.-Natur. Reihe **13** (1964), 41–53.

Die Autoren untersuchen die folgende singuläre Integralgleichung mit Cauchyschen Hauptwertintegralen

$$(1) \qquad A(t_0)\varphi(t_0) + \sum_{\nu=1}^{n}\frac{B_\nu(t_0)}{\pi i}\int_L \frac{C_\nu(t)\varphi(t)}{t-t_0}\,dt = f(t_0), \quad t_0 \in L,$$

worin L ein System von p glatten und doppelpunktfreien, getrennt liegenden Bogen L_j in der komplexen z-Ebene bezeichnen mögen. Gegeben sind die Funktionen $A(t)$, $B_\nu(t)$, $C_\nu(t)$ und $f(t)$, die auf L einer Hölderbedingung genügen sollen, während die gesuchte Funktion $\varphi(t)$ in jedem abgeschlossenen Teilbogen der L_j, der keinen der Endpunkte c enthalte, einer gleichmäßigen Hölderbedingung

$$(2) \qquad |\varphi(t_1) - \varphi(t_2)| \leq A\cdot|t_1 - t_2|^\mu, \qquad 0 < \mu \leq 1,\ A > 0,$$

genügen soll. In den Umgebungen der Endpunkte c gelte $\varphi(t) \in H^*$, d.h.

(3) $\varphi(t) = \varphi^*(t)\cdot(t-c)^{-\gamma}$ mit $\gamma = \alpha + i\beta$, $0 \leq \alpha < 1$,

und dort Hölderstetigem $\varphi^*(t)\cdot(t-c)^\gamma$ sei ein beliebiger Zweig der sich für $t \in L$ stetig ändert. Weiterhin wird vorausgesetzt:

(4) $$A^2(t) - \left[\sum_{\nu=1}^{n} B_\nu(t)\cdot C_\nu(t)\right]^2 \neq 0 \quad \text{für alle} \quad t \in L.$$

Im Spezialfall $n=1$, $B_1(t)=1$ oder $C_1(t)=1$ ist eine explizite Lösung von (1) in dem Buche von N. I. Mushelišvili [*Singular integral equations* (russisch), OGIZ, Moscow, 1946; MR 8, 586] angegeben. Wie in diesem Buche führen die beiden Autoren hier (1) auf ein Hilbertsches Randwertproblem zurück. Sie definieren dazu:

(5) $$\Phi_\nu(z) = \frac{1}{2\pi i}\int_L \frac{C_\nu(t)\varphi(t)}{t-z}\,dt \quad \text{für } \nu = 1, \cdots, n,\ z \notin L,$$

welches außerhalb L holomorphe und im Unendlichen verschwindende Funktionen sind. Die Formeln von Sokhoski-Plemelj besagen unter anderem

(6) $C_\nu(t)\varphi(t) = \Phi_\nu^+(t) - \Phi_\nu^-(t)$ für $\nu = 1, \cdots, n$, $t \in L$,

wenn $\Phi_\nu^\pm(t)$ die Randwerte von $\Phi_\nu(z)$ für $z \to t \in L$ von links bzw. rechts bei gegebener Orientierung der Bogen L_j von L bezeichnen. Nach einigen Umformungen resultieren die folgenden Randwertrelationen, die zur Integralgleichung (1) völlig äquivalent sind:

(7) $$\Phi_\mu^+(t) - \Phi_\mu^-(t) = \left[-2C_\mu(t)\cdot\sum_{\nu=1}^{n} B_\nu(t)\cdot\Phi_\nu^-(t) + C_\mu(t)\cdot f(t)\right]$$
$$\cdot\left[A(t) + \sum_{\lambda=1}^{n} B_\lambda(t)\cdot C_\lambda(t)\right]^{-1}, \qquad \mu = 1, \cdots, n,\ t \in L.$$

In Vektorschreibweise lauten die Relationen

(8) $$\Phi^+(t) = G(t)\cdot\Phi^-(t) + g(t) \quad \text{für } t \in L,$$

wobei die Elemente $G_{\mu\nu}(t)$ der Matrix $G(t)$ die spezielle Form haben

(9) $$G_{\nu\nu}(t) = 1 + \varepsilon_\nu(t)\cdot\delta_\nu(t), \qquad G_{\mu\nu}(t) = \varepsilon_\mu(t)\cdot\delta_\nu(t) \quad \text{für } \mu \neq \nu.$$

Das Hilbertsche Randwertproblem (8) für den außerhalb L holomorphen Funktionenvektor $\Phi(z)$ ist in der bekannten Weise [siehe das Buch von N. I. Mushelišvili, Kap. 18, S. 381, loc. cit.] so zu lösen, daß erst die Lösungen des homogenen Problems ($g(t)=0$) bestimmt werden und dann eine spezielle Lösung der inhomogenen Aufgabe konstruiert wird. Die Hauptschwierigkeit dabei ist das Auffinden einer homogenen Lösungsbasis, die die Autoren für die Spezialfälle (a) die $\delta_\nu(t)$ sind—abgesehen von einem gemeinsamen Faktor— Polynome, (b) die $\varepsilon_\mu(t)$ sind Polynome—bis auf einen gemeinsamen Faktor, (c) $A(t)=0$, $B_1(t)=C_2(t)$, $B_2(t)=C_1(t)$ $(n=2)$ mit $C_1\cdot C_2 \neq 0$ jedoch explizit angeben können.

Im dritten Abschnitt reduzieren die Autoren das Integralgleichungssystem für $\gamma_k(\xi)$, $k=0, \cdots, N-1$:

(10) $$q_l(x) = \frac{1}{2aN}\sum_{k=0}^{N-1}\int_{-c}^{+c}\gamma_k(\xi) \cdot \frac{e^{\pi i(l-k)/aN}\sinh(\pi(x-\xi)/aN) + \sin^2(\pi(l-k)/N)}{\sinh^2(\pi(x-\xi)/aN) + \sin^2(\pi(l-k)/N)}\,d\xi,$$

$l=0, 1, \cdots, N-1$; $-c < x < +c$; auf N Integralgleichungen vom speziellen Typus (c). Dieses Integralgleichungssytem tritt in der Aerodynamik instationärer Gitterströmungen auf und wurde von H. Söhngen und dem Referenten [Z. Angew. Math. Mech. 38 (1958), 442–465; MR 21 #1067] aufgestellt. Die explizite Lösung von (10) mit der Nebenbedingung $\gamma_k(\xi) = O(1)$ für $\xi \to c$ ist zu lang, als daß sie hier niedergeschrieben werden könnte.

Čibrikova, L. I. 5077

On the solution of some complete singular integral equations. (Russian)

Kazan. Gos. Univ. Učen. Zap. **122** (1962), *kn.* 3, 95–124.

The solutions of several singular integral equations are given. Some of these equations have the Hilbert kernel $\cot\frac{1}{2}(t-x)$, and $\sin\frac{1}{2}(t-x)$. Other kernels involve Jacobi's theta function. The consideration of equations with such kernels leads to the Riemann boundary-value problem for doubly periodic functions. Equations with periodic and quasi-periodic kernels are studied. The number of solutions of Riemann's boundary-value problem corresponding to a given integral equation is determined completely by the index of the equation, and it is shown to be independent of the type of the fundamental region.

H. P. Thielman (Alexandria, Va.)

Guseinov, A. I.; Muhtarov, H. Š. 5078

Some properties of a linear singular integral operator with Hilbert kernel in a generalized Hölder class. (Russian. Azerbaijani summary)

Akad. Nauk Azerbaĭdžan. SSR Dokl. **20** (1964), *no.* 3, 3–8.

Let H be the class of periodic functions $U(x)$ of period 2π such that $|U(x+\Delta x) - U(x)| \leq \sum_{n=1}^{\infty} K_n|\Delta x|^{\delta_n}$ for some sequences $0 < \delta_n < 1$ and $0 \leq K_n$, where $\delta_n \to 0$ and $\sum_{n=1}^{\infty} K_n < \infty$. Then if $\sum_{n=1}^{\infty}(K_n/\delta_n) < \infty$, the function $V(x) = (1/2\pi)\int_{-\pi}^{\pi} U(s)\cot\frac{1}{2}(s-x)\,ds$ is also in H. If $f(x, s)$ is in H as a function of both variables and $\delta_n(s) < \delta_n(x)$, then if $\sum_{n=1}^{\infty}(K_n(s)/\delta_n(s)) < \infty$ and $\sum_{n=1}^{\infty}(K_n(x)/(\delta_n(x) - \delta_n(s))) < \infty$, the function $\varphi(x) = \int_{-\pi}^{\pi} f(x, s)\cot\frac{1}{2}(s-x)\,ds$ is in H.

Krupnik, N. Ja. 5079

Higher-dimensional singular operators in spaces of fundamental and generalized functions. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 41–44.

The author extends some results on elliptic systems of singular integral operators on Euclidean space E_m to new classes of functions, and with fewer restrictions on the kernels than are usually made. The operators are of the form $A\varphi(x) = a(x)\varphi(x) + \lim_{\varepsilon\to 0}\int h(x, x-y)\,dy$, where $h(x, z)$ is homogeneous of degree m in z and $\int_{|z|=1} h(x, z)\,d\sigma_z = 0$, and the adjoints of these. The symbol of A is $\sigma(A)(x, \zeta) = a(x) + \lim_{\varepsilon\to 0}\int_{\varepsilon<|z|<\varepsilon^{-1}} e^{-i(z,\zeta)}h(x, z)\,dz$. $\sigma(A)$ is said to be in G_n if $\sigma(A)(x, \zeta)$ and certain of its derivatives extend continuously on $S^m \times S^{m-1}$, where S^m is the one-point compactification of the sphere and S^{m-1} is $\{|\zeta| = 1\}$; and the derivatives $D_x^{\,q}D_\zeta^{\,p}\sigma(A)(x, \zeta)$ of order $q+p$, with $q \leq n$ and $p \leq m + [m/2] + 2$, are not too bad. These operators act on the Sobolev spaces $W_p^{\,l}(E_m)$ $(1 < p < \infty,\ |l| \leq n)$, and for

$n=\infty$, on the space $\mathcal{M}$ of functions all of whose derivatives are $O(|x|^{\varepsilon-n})$ for all $\varepsilon>0$, as $|x|\to\infty$. In either case, the author states the usual theorem: If $\inf|\sigma(A)|>0$, then A has closed range of finite codimension, and a finite null space. Further, the index of A is the same on all these spaces. He does not suggest that any very new techniques are necessary for these results, or that the assumptions on $\sigma(A)$ cannot be further reduced.

He concludes with a result showing that non-zero operators of the type considered here cannot map certain types of spaces into others; these are such as to make the choice of $\mathcal{M}$ (as above) appear reasonable.

R. T. Seeley (Waltham, Mass.)

Massera, J. L. 5080

Sur une équation intégrale provenant d'un problème de mécanique des fluides. (Spanish summary)

Bol. Fac. Ingen. Agrimens. Montevideo **8** (1962), 27–43.

The author investigates the integral equation

$$\int_{x-1}^{x}[f(x)-f(t)]^{-1/2}\,dt = A,$$

where A is a constant. The integral equation is to be satisfied for $x\geqq 0$, and $f(x)$ must coincide with a given, bounded, measurable function $f_0(x)$ on the interval $-1\leqq x<0$.

A continuous function $\bar f$ is constructed to satisfy the integral equation except possibly on a set of the first category; this function $\bar f$ becomes a strict solution for all $x\geqq 0$ if f_0 satisfies the additional condition

$$f_0(y)-f_0(x) \geqq p_0(y-x) \quad \text{for some } p_0>0,$$
$$-1\leqq x\leqq y<0.$$

The author derives a number of properties of $\bar f$ and lists some related unsolved questions.

I. Stakgold (Evanston, Ill.)

Plamenevskiĭ, B. A. 5081

Singular integral equations on an infinite cylinder. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 780–783.

Let $x\in R^k$, $y\in R^{m-k}$, $(x,y)\in R^m$ be points in Euclidean space, and let $C_{m,k}$ be the cylinder obtained from R^m by reducing the first k variables mod 1. For u in $L^1(C_{k,m})$, let $\hat u(n,y)$ (n a k-tuple of integers) be the Fourier transform of u. The author considers operators of the form

$$(1)\quad Au(\bar x,\bar y) = \sum_n\int_{R^{m-k}}\phi(\bar x,\bar y;n,y)\hat u(n,y)e^{i(2\pi n,\bar x)+i(y,\bar y)}\,dy,$$

where $\phi(\bar x,\bar y;x,y)$ is bounded, measurable, and periodic in $\bar x$ with period 1, and homogeneous of degree zero in (x,y). From the results of Marcinkiewicz and Mihlin on the multipliers of Fourier series and integrals, he concludes that if ϕ is independent of $(\bar x,\bar y)$, and if the derivatives of $\phi(\bar x,\bar y;x,y)$ with respect to x and y of order $\leqq m$ are continuous for $|x|^2+|y|^2>0$, then A is bounded on $L^p(C_{m,k})$ for $1<p<\infty$. Then, by expanding $\phi(\bar x,\bar y;x,y)=\sum a_{jl}(\bar x,\bar y)Y_{jl}(x,y)$ in spherical harmonics, he concludes that if the derivatives of $\phi(\bar x,\bar y;x,y)$ with respect to x and y of order $\leqq l$ ($l\geqq\frac12 m-1$) are square integrable on $|x|^2+|y|^2=1$, then the same result holds. Finally, if ϕ_1 and ϕ_2 have, in addition, limits as $\bar y\to\infty$, and A_j corresponds to ϕ_j as in (1), while A corresponds to the product $\phi_1\phi_2=\phi$, then $A-A_1A_2$ is compact on $L^p(C_{m,k})$ for $1<p<\infty$.

R. T. Seeley (Waltham, Mass.)

Mac Nerney, J. S. 5082

A nonlinear integral operation.

Illinois J. Math. **8** (1964), 621–638.

This paper extends the theory of solutions of a general linear integral equation developed earlier [same J. **7** (1963), 148–173; MR **26** #1726] to a nonlinear case. S is a linearly ordered set of elements x, y, z; G is a normed complete Abelian group of elements P, Q; H is the class of all functions on G to G to which $\{0,0\}$ belongs, with 1 the identity function. Then addition in H is defined in the usual way, but the product h_2h_1 is $h_2(h_1(P))$. For interval functions $U(x,y)$ to H, it is then possible to define sum integrals $\int_x{}^y$ or ${}_x\sum^y$ and product integrals ${}_x\prod^y$. Product integrals of this type were introduced by G. Birkhoff [J. Math. Phys. Mass. Inst. Tech. **16** (1937), 104–132]. As in the linear case, it is shown that there exists a correspondence between the class $\mathcal{OA}$ of additive (interval) functions $V(x,y)$ to H subject to a Lipschitz condition that there exists a non-negative additive $\alpha(x,y)$ such that for P and Q in G, we have $\|V(x,y)P-V(x,y)Q\|\leqq\alpha(x,y)\|P-Q\|$ and the class $\mathcal{OM}$ of multiplicative (interval) functions $W(x,y)$ to H satisfying the Lipschitz condition that there exists a real-valued multiplicative function $\mu(x,y)\geqq 1$ such that for all P and Q in G we have

$$\|(W(x,y)-1)P-(W(x,y)-1)Q\| \leqq (\mu(x,y)-1)\|P-Q\|.$$

This correspondence is determined by the conditions $V(x,y)P={}_x\sum^y[W-1]P$ and $W(x,y)P={}_x\prod^y[1+V]P$. If $V(x,y)$ belongs to $\mathcal{OA}$ and $u(x)$ on S to G satisfies a bounded variation condition that there exists a non-negative $\beta(x,y)$ such that $\|u(x)-u(y)\|\leqq\beta(x,y)$, then the integral $\int_x{}^y V\cdot u$ based on $V(s,t)u(t)$ exists and the solution of the integral equation $u(x)=P+\int_x{}^c V\cdot u$ is given by $u(x)=W(x,c)P$. This solution can also be obtained by iteration based on $h_n(x)=P+\int_x{}^c V\cdot h_{n-1}$, where h_0 can be assumed to belong to the extension by uniform convergence of functions of the type $u(x)$. The theory is extended to the case when S is replaced by a canonically ordered semi-group. There is an example related to the differential equation for the arctangent function.

Douady, Adrien 5084

Espace des sous-modules d'un module de Banach.

C. R. Acad. Sci. Paris **258** (1964), 5783–5785.

The author studies the local structure of the set $\mathcal{G}_A(E)$ of

trong submodules of a Banach module E over a Banach lgebra with unit A, considered as a subspace of the nalytic Banach manifold $\mathscr{G}(E)$ of the strong subspaces, he grassmannian of E. Attention is thus focused on strong ubspaces and strong homomorphisms; each such subpace is closed and has a closed supplementary subspace, nd each such homomorphism has a strong kernel and a trong image. Theorem: Let E be a Banach A-module, $F \in \mathscr{G}_A(E)$ be 1-presentable such that $\mathrm{Ext}_A{}^1(F; E/F)$ be trong. There exists a submanifold S of $\mathscr{G}(E)$, containing F nd such that the tangent space to S at F is $\mathrm{Hom}_A(F; E/F)$, nd there is an analytic mapping ω of S into $\mathrm{Ext}_A{}^1(F; E/F)$ uch that $\omega^{-1}(0)$ and $\mathscr{G}_A(E)$ coincide around F. In addition, is tangent to 0, and its expansion limited to second order s given by $f \to f^* f_*(\alpha)$, where α is the element of $\mathrm{Ext}_A{}^1(E/F; F)$ corresponding to the exact sequence $\to F \to E \to E/F \to 0$. The proof is based on suitable implicit function and fibration arguments.

Garling, D. J. H. 5085

Weak Cauchy sequences in normed linear spaces.

Proc. Cambridge Philos. Soc. **60** (1964), 817–819.

The author proves the following propositions. (1) If a subpace of (c_0) is isomorphic to the dual of a normed linear pace, it is finite-dimensional. {From the author's arguments it follows only that if a subspace of (c_0) is isometrically isomorphic to the dual of a normed linear space, hen it is finite-dimensional. However, proposition (1) s true and follows easily from Theorem 4 of Bessaga nd Pełczyński [Studia Math. **17** (1958), 151–164; MR **22** #5872].} (2) If the unit ball of a normed linear space E is ontained in the closed absolutely convex cover of the weak Cauchy sequence of points of E, then E is finite-dimensional. (3) If $(E, \|\ \|, \|\ \|^*)$ is an infinite-dimensional -compact two-norm space, and if $(E, \|\ \|)$ is a reflexive Banach space, then there exists no γ-Cauchy sequence whose γ-closed absolutely convex cover contains the γ-ompact set $\{x : \|x\| \leq 1\}$.

Edwards, R. E. 5087

A fixed point theorem with applications to convolution equations.

J. Austral. Math. Soc. **3** (1963), 385–395.

Edelstein [J. London Math. Soc. **37** (1962), 74–79; MR **24** #A2936] proved the following extension of Banach's contraction principle: If F is a self-map of a metric space M uch that $d(F(x), F(y)) < d(x, y)$ for any distinct x and y in M, and if x_0 is a point of M such that the sequence of terates $x_n = F^n(x_0)$ contains a convergent subsequence, then the limit of this subsequence is the unique fixpoint of F.

The author applies this result to a subset M of a topological vector space with a suitable choice of metric. He obtains some general theorems which are then applied to convolution equations over groups.

I. N. Baker (London)

Lindenstrauss, Joram 5088

On nonlinear projections in Banach spaces.

Michigan Math. J. **11** (1964), 263–287.

Let Y be a metric space, let X be its subspace isometric to a Banach space (i.e., if $d(\ ,\ )$ is the metric of Y and $\|\cdot\|$ is the norm of X, then $d(x_1, x_2) = \|x_1 - x_2\|$ for $x_1, x_2 \in X$). A mapping $r : Y \to X$ is said to be a uniform projection [lipschitzian projection] if r is uniformly continuous [satisfies a Lipschitz condition] and $rx = x$ for each x in X. The main subject of the paper under review is the study of such projections.

The author shows that if Y itself is a normed linear space, then the existence of such projections is closely related to the existence of bounded linear projections. In fact, the following surprising result is obtained: Let Y be a normed linear space, let X be a closed linear subspace of Y, and let there exist a uniform projection from Y onto X. Then there exists a bounded linear mapping $T : Y \to X^{**}$ such that $Tx = \kappa x$ for $x \in X$, where $\kappa : X \to X^{**}$ is the canonical embedding, and X^{**} denotes the second dual to X. Hence, if there exists a bounded linear projection from X^{**} onto X (in particular, if X is reflexive, more generally, if X is isomorphic to a conjugate space to a Banach space, or if X is an abstract L-space), then the existence of a uniform projection on X implies the existence of a bounded linear one. Dual results on uniformly continuous liftings and other interesting corollaries are given. If there is no bounded linear projection from X^{**} onto κX, then, in general, the existence of a uniform projection does not imply the existence of a bounded linear one (an example: the space m and its subspace c_0). This is a consequence of the following results generalizing results of J. R. Isbell [Pacific J. Math. **11** (1961), 609–648; MR **25** #4487]. Let $C_u(K)$ denote the space of all bounded real-valued and uniformly continuous functions (with the sup norm) on a metric space K. Then for every metric space Y which contains $C_u(K)$ isometrically there is a lipschitzian projection from Y onto $C_u(K)$. A similar result is true in the case where K is a one-point compactification of a discrete set as well as in a slightly more general situation. If K is an arbitrary compact Hausdorff space, then it is shown only that for every metric space Y containing isometrically the space $C(K) = C_u(K)$ and such that the set $Y \setminus C(K)$ is finite, there is a lipschitzian projection from Y onto $C(K)$ (with a Lipschitz constant ≤ 2).

If X is a uniformly convex Banach space with modulus of convexity $\delta(\varepsilon)$, then (1) from every metric space $Y \supset X$ with $d(y, X) \leq \alpha$ for all $y \in Y$ there is a uniform projection onto X whose modulus of continuity $\phi(\varepsilon)$ satisfies the condition $\phi(\varepsilon) \leq K\alpha\delta^{-1}(\varepsilon/\alpha)$; (2) from every metric space $Y \supset S_X(0, 1)$ ($S_X(0,1)$ denotes the unit cell of X) there is a uniform projection onto $S_X(0, 1)$ whose modulus of continuity $\phi(\varepsilon)$ satisfies the condition $\phi(\varepsilon) \leq K\delta^{-1}(\varepsilon)$ (K is a universal constant which does not depend on X and Y). It is shown that in the case of $L_p(\mu)$-spaces these moduli of continuity are in a sense the best possible. This implies in

particular that the Banach space $X=(l_{p_1}\oplus l_{p_2}\oplus\cdots)$, with $p_k\to+\infty$ is not a uniformly continuous retract of any of its uniform neighbourhoods in m. This is a solution of a problem raised by Isbell [loc. cit.].

The results given above are applied to the problem of the classification of Banach spaces with respect to the equivalent uniform structures [cf. C. Bessaga and the reviewer, General Topology and its Relations to Modern Analysis and Algebra (Proc. Sympos., Prague, 1961), pp. 87–90, Academic Press, New York, 1962; MR 26 #2855]. Banach spaces X and Y are said to be uniformly homeomorphic provided that there exists a homeomorphism T from X onto Y such that both T and T^{-1} are uniformly continuous. The author shows: (a) A space $C(K)$ is not uniformly homeomorphic to any reflexive infinite-dimensional Banach space (more generally, to any Banach space X such that there is a projection from X^{**} onto κX, but X is not a $\mathfrak{P}$-space, i.e., X does not have the extension property); (b) If $X_1=L_{p_1}(\mu_1)$, $X_2=L_{p_2}(\mu_2)$, and if $p_1>\max(2,p_2)$, then X_1 is not uniformly homeomorphic to X_2; (c) There is a reflexive space which is not uniformly homeomorphic to any uniformly convex space; (d) The space c_0 has an uncountable number of mutually non-uniformly homeomorphic closed linear subspaces.

Another application is a partial negative answer to a problem of Smirnov [cf. E. A. Gorin, Uspehi Mat. Nauk 14 (1959), no. 5 (89), 129–134; MR 22 #967] whether $C[0,1]$ is uniformly homeomorphic to a subset of l_2.

Lindenstrauss, Joram 5089

On the extension of operators with range in a $C(K)$ space.

Proc. Amer. Math. Soc. 15 (1964), 218–225.

Theorem: Let K be a compact Hausdorff space and let $X=C(K)$ be the space of all the continuous real-valued functions on K with the supremum norm. The following four statements are equivalent. (i) For every two Banach spaces $Z\supset Y$ with $\dim(Z/Y)=1$ and every operator T from Y into X with a separable range there is an extension $\hat{T}$ of T from Z into X with $\|\hat{T}\|=\|T\|$. (ii) For every two Banach spaces $Z\supset Y$ with $\dim Y=2$, $\dim Z=3$ and every operator T from Y into X there is an extension $\hat{T}$ of T from Z into X with $\|\hat{T}\|=\|T\|$. (iii) There is a $\lambda<2$ such that for every two Banach spaces $Z\supset Y$ with $\dim(Z/Y)=1$ and every operator T from Y into X with a separable range there is an extension $\hat{T}$ of T from Z into X with $\|\hat{T}\|\leq\lambda\|T\|$. (iv) K is an F-space in the terminology of the reviewer and Henriksen [Trans. Amer. Math. Soc. 82 (1956), 366–391; MR 18, 9], that is, for every $f\in C(K)$ there is a $g\in C(K)$ such that $f(k)>0$ implies $g(k)\geqq 1$ and $f(k)<0$ implies $g(k)\leqq -1$. Furthermore, if the continuum hypothesis is true, then the following statement is also equivalent to the preceding ones. (v) For every two Banach spaces $Z\supset Y$ and every operator T from Y into X with a separable range there is an extension $\hat{T}$ of T from Z into X with $\|\hat{T}\|=\|T\|$. The author remarks that the equivalence of (i) with (iv) is essentially due to Aronszajn and Panitchpakdi [Pacific J. Math. 6 (1956), 405–439; MR 18, 917].

Nirenberg, R.; Panzone, R. 5090

On the spaces L^λ which are isomorphic to a B^*.

Rev. Un. Mat. Argentina 21, 119–130 (1963).

The present paper concerns the problem of Dieudonné [Arch. Math. 10 (1959), 151–152; MR 21 #3763]: "characterize abstract L-spaces which are (isometrically) isomorphic to the dual of another Banach space". The authors discuss the actual situation of this subject (an exhaustive list of references is given). Under a certain very special additional assumption (too complicated to state here) the authors show that a space $L_1(X,\Sigma,\mu)$ for σ-finite μ is not isomorphic to a dual space of a subspace of $L_\infty(X,\Sigma,\mu)$.

On the Weierstrass approximation theorem.

C. R. Acad. Bulgare Sci. 17 (1964), 789–792.

In this generalization of the Weierstrass theorem, the problem is to approximate a continuous, vector-valued function defined on a compact, convex subset A of a Banach space X. The approximating functions are obtained by averaging with respect to a non-negative measure on the Borel subsets of X. The usual form of the Weierstrass theorem is obtained when A is a rectangle and X is R^n.

Thorp, E. O. 5093

Some Banach spaces congruent to their conjugates.

J. London Math. Soc. 39 (1964), 703–705.

The author exhibits a large class of Banach spaces Z which are congruent (i.e., isometrically isomorphic) to their conjugates Z^*. Starting from a space $(X,|\cdot|)$ which is congruent to X^{**}, endow the direct sum $Z=X\oplus X^*$ with a norm $\|(x,x^*)\|=\|(|x|,|x^*|)\|$, derived from a norm $\|\cdot\|$ on R^2 which coincides on the non-negative quadrant with some multiple of the Euclidean one. An implementing congruence $\varphi: Z^*\to Z$ is defined by $\varphi(z^*)=(z_1^*,z_2^*)$, where $z_1^*(x)=z^*((x,0))$ and $z_2^*(x^*)=z^*((0,x^*))$. {The reviewer points out that E. R. Lorch has established a similar result, however, with the Euclidean norm in R^2 [cf. Ann. of Math. (2) 46 (1945), 468–473; MR 7, 125]; Lorch also gives a more restrictive interpretation of selfadjointness, leading to a characterization of Hilbert space.}

On Beurling-Livingstone's theory on the Banach space with duality mapping.

Yokohama Math. J. 11 (1963), 1–4.

It is proved here that if a conditionally σ-complete Banach lattice admits a duality mapping T such that $x\cap y=0$ implies $T(x+y)=T(x)+T(y)$, then, whenever we have $x=x_1+x_2$, $y=y_1+y_2$ with $x_1\cap x_2=0$, $y_1\cap y_2=0$, $\|x_i\|=\|y_i\|$, we also have $\|x\|=\|y\|$. A discussion of some consequences is given.

Intermediate spaces and interpolation, the complex method.

Studia Math. **24** (1964), 113–190.

[...]is is the complete version of the author's results on [...]termediate (or interpolation) spaces, part of which were [...]nounced already several years ago at a meeting in War[...]w [see Studia Math. (Ser. Specjalna) Zeszyt 1 (1963), 31–[...]; MR **26** #5409]. Let (B^0, B^1) be a couple of Banach [...]aces, B^0 and B^1 being both continuously imbedded in [...]me topological vector space V. Let $\mathscr{F}(B^0, B^1)$ be the [...]nach space (with the natural norm) of functions with [...]lues in $B_0 + B_1$, boundedly continuous in the strip [...]$\leq s \leq 1$ of the complex $(s+it)$-plane, analytic in its [...]terior $0 < s < 1$ and such that $f(it) \in B^0$ and tends to 0 in [...] as $|t| \to \infty$, and $f(1+it) \in B^1$ and tends to 0 in B^1 as [...]$\to \infty$. The basic intermediate spaces, denoted by $B_s = [B^0, B^1]_s$, $0 \leq s \leq 1$, are now obtained as the Banach space [...]ith the natural norm) spanned by $f(s)$ when f runs [...]rough $\mathscr{F}(B^0, B^1)$. (The same definition, indeed, in a [...]mewhat more general form, was also found inde[...]ndently by Lions [C. R. Acad. Sci. Paris **251** (1960), [...]53–1855; MR **22** #9859].) It is trivial to verify the fol[...]wing interpolation theorem: Let (B^0, B^1) and (C^0, C^1) be [...]o couples and let T be a linear mapping from $B^0 + B^1$ [...]o $C^0 + C^1$ such that T (when restricted to B^0) $\in \mathscr{L}(B^0, C^0)$ [...]d (when restricted to B^1) $\in \mathscr{L}(B^1, C^1)$. Then T (when restricted to B_s) $\in \mathscr{L}(B_s, C_s)$, with a corresponding convexity inequality $M \leq M_0^{1-s} M_1^{s}$, where M_0, M_1, M are the operator norms in question. Similar results hold for multilinear mappings. For technical reasons certain other intermediate spaces, denoted by $B^s = [B^0, B^1]^s$, $0 \leq s \leq 1$, are also used, the definitions of which are analogous. It is trivial to see that $B_s \subset B^s$. If one of the spaces, say B^0, is reflexive, one can show also the converse $B^s \subset B_s$, so that $B_s = B^s$ in this case. However, a concrete counterexample shows that $B_s \neq B^s$ in general. An important result is a duality theorem claiming that $([B^0, B^1]_s)^1 = [(B^0)^1, (B^1)^1]^s$ provided $B^0 \cap B^1$ is dense in both B^0 and B^1. The theory is applied to some concrete cases, in the first place, to Banach-space-valued Banach lattices $X(B)$. It is shown that, under certain assumptions, $[X_0(B^0), X_1(B^1)]_s = X(B) = [X_0(B^0), X_1(B^1)]^s$, where $B = [B^0, B^1]_s$ and $X = X_0^{1-s} X_1^{s}$, this latter Banach lattice being obtained as follows: $\varphi \in X_0^{1-s} X_1^{s}$ if and only if there exist $\varphi_0 \in X_0$ and $\varphi_1 \in X_1$ such that, for each point x of the measure space $\mathscr{M}$ in question, $|\varphi(x)| \leq |\varphi_0(x)|^{1-s} |\varphi_1(x)|^{s}$. A similar result is given for a general class of Lipschitz-type spaces $\Lambda(X, B)$ obtained as follows: One assumes that a continuous group of operators $G(t)$, $t \in R^n$, acts in B and that X is a Banach lattice on R^n. Then $\Lambda(X, B)$ is, roughly speaking, the subspace of B defined by the relation $\|G(t)b - b\| \in X$ or a similar relation with a higher-order difference; the relation depends on the growth properties of the functions in X. The presentation is not very clear, mainly owing, in the reviewer's opinion, to the unfortunate subdivision into two parts, the first giving the definitions and main results, the second giving the detailed proofs; the reader has to spend quite a lot of time just searching for the relevant passage for the proof of each particular statement.

Gudiev, A. H. 5098

An imbedding theorem for the trace in abstract functions. (Russian)

Dokl. Akad. Nauk SSSR **147** (1962), 764–767.

L'auteur démontre de nouveaux théorèmes d'immersion pour les espaces de Sobolev $W_p^{(l)}(\Omega)$ (espace des fonctions dont les dérivées d'ordre $\leq l$ sont de puissance p sommable dans Ω, ouvert de R^n).

On désigne par $L_{(p_1, p_2)}(\Omega)$ l'espace des fonctions qui sont des restrictions à Ω de fonctions f définies dans R^n et telles que

$$\left\{\int_{R^{n-s}} \left(\int_{R^s} |f(\mathrm{x}_s, \mathrm{x}_{n-s})|^{p_1}\, d\mathrm{x}_s\right)^{p_2/p_1} d\mathrm{x}_{n-s}\right\}^{1/p_2} < +\infty$$

$(\mathrm{x}_s = (x_1, x_2, \cdots, x_s)$ décrit l'espace R^s et $\mathrm{x}_{n-s} = (x_{s+1}, \cdots, x_n)$ décrit l'espace R^{n-s}). Alors pour $n/p - l < (n-s)/p_2 + s/p_1$, $p_2 \geq p_1 \geq p > 1$, on a l'immersion de $W_p^{(l)}(\Omega)$ dans $L_{(p_1, p_2)}(\Omega)$. L'auteur démontre également des résultats plus généraux (immersion dans les espaces $L_{(p_1, p_2, \cdots, p_k)}(\Omega)$ de définition évidente). Aucune hypothèse particulière n'est faite sur Ω bien que la formule de représentation de Sobolev [*Some applications of functional analysis in mathematical physics* (Russian), Izdat. Leningrad. Gos. Univ., Leningrad, 1950; MR **14**, 565] soit utilisée. *P. Grisvard* (Nancy)

Guglielmino, Francesco 5099b

A proposito di un teorema riguardante alcuni spazi di interpolazione. (English summary)

Boll. Un. Mat. Ital. (3) **19** (1964), 171–177.

Sur un ensemble Q mesurable de $R_x^m \times R_y^n$, on désigne par $L^{p_1,p_2}(Q)$ l'espace des (classes de) fonctions qui sont L^{p_1} en x et L^{p_2} en y. L'auteur étudie les espaces de traces [comme dans le rapporteur, Math. Scand. **9** (1961), 147–177; MR **28** #2429] entre $L^{p_1,p_2}(Q)$ et $L^{q_1,q_2}(Q)$; il donne diverses inclusions selon les valeurs des paramètres p, q et des paramètres des espaces de traces considérés. Comme conséquence on a un théorème d'interpolation pour les opérateurs linéaires entre ces espaces, théorème qui généralise le théorème classique de M. Riesz et qui complète, en autorisant les valeurs infinies pour les divers paramètres, un résultat (établi de façon complètement différente) de Benedek et Panzone [Duke Math. J. **28** (1961), 301–324; MR **23** #A3451]. Une difficulté de mesurabilité est résolue dans le second article.

J. L. Lions (Paris)

Hadžiivanov, Nikolaĭ 5100

On indecomposable elements of two cones. (Bulgarian. Russian summary)

Annuaire Univ. Sofia Fac. Sci. Phys. Math. Livre 1 *Math.* **56** (1961/62), 191–194 (1963).

The author finds the extreme elements of two cones of multiple sequences. The extreme elements of the cone K_n of the multiple sequences $\{a_{\nu_1\cdots\nu_n}\}_{\nu_i=0}^{\infty}$ which satisfy the equations

$$(1)\qquad (-1)^{\nu_1+\cdots+\nu_n}\Delta^{\nu_1}\cdots\Delta^{\nu_n}a_{k_1\cdots k_n} \geqq 0$$
$$(\nu_i = 0, 1, 2, \cdots;\ k_i = 0, 1, 2, \cdots)$$

are sequences of the type $\{cq_1^{\nu_1}\cdots q_n^{\nu_n}\}_{\nu_i=0}^{\infty}$; $c>0$; $0 \leqq q_i \leqq 1$; $i = 1, 2, 3, \cdots, n$.

The extreme points of the cone L_n are also found, where L_n is defined in the same manner as K_n, but with the condition that

$$\sum_{\nu_1=0}^{m_1}\cdots\sum_{\nu_n=0}^{m_n}(-1)^{\nu_1+\cdots+\nu_n} \times \binom{m_1}{\nu_1}\cdots\binom{m_n}{\nu_n}a_1^{\nu_1}\cdots a_n^{\nu_n}a_{k_1+m_1+\cdots+k_n+m_n} \geqq 0$$

instead of (1). {The paper contains some troublesome misprints.}

Ishii, Jyun 5101

A remark on the space D_Φ^h.

Sci. Rep. Fac. Lit. Sci. Hirosaki Univ. **10** (1963), 1–4.

Let E be a measure space and $h(t)$ an unbounded positive measurable function such that if $E_\nu = \{t : h(t) \leqq \nu\}$, then $\mu(E_\nu) < \infty$. D_Φ^h is the totality of measurable functions $x(t)$ such that $\|x\|_\Phi + \|xh\|_\Phi < \infty$, where $\|\ \|_\Phi$ is a norm on the Orlicz space L_Φ and $xh = x(t)h(t)$. The properties of D_Φ^h are precisely what one would expect, and the author proves them by considering D_Φ^h as a modulared function space. Theorem 1: $D_\Phi^h \subseteq D_{\Phi_1}^h$ if and only if there exists $k>0$ such that $\Phi_1(\xi) \leqq \Phi(k\xi)$. Theorem 2: D_Φ^h is separable if and only if Φ satisfies the Δ_2 condition of Orlicz. Theorem 3: D_Φ^h is a regular (i.e., reflexive) Banach space if and only if Φ and $\bar\Phi$ satisfy the Δ_2 condition.

McLachlan, E. K. 5102

Extremal elements of the convex cone B_n of functions.

Pacific J. Math. **14** (1964), 987–993.

Let B_0 denote the set of non-negative continuous functions on $[0, 1]$; B_1 the set of $f \in B_0$ such that $\Delta_h f(x) = f(x+h) - f(x) \geqq 0$ for $h>0$ and $[x, x+h] \subset [0, 1]$; and B_n $(n>1)$ the set of $f \in B_{n-1}$ such that $\Delta_h^n f(x) \geqq 0$ for $h>0$ and $[x, x+nh] \subset [0, 1]$. Then B_n is a convex cone. The principal results of this paper specify exactly the extremal elements of B_n and (by using a general theorem of Choquet) give an integral representation of elements of $C_n = \{f \in B_n : f(1) = 1\}$ in terms of a positive measure on the pointwise closure in $B_n - B_n$ of the set of extremal points of C_n.
